The Lord Penzance hybrid Sweetbriers have proved themselves good growers, and are hardy and satisfactory here. The flowers are usually larger and of finer coloring than those of the parent Sweetbrier, while the foliage of all is pleasantly fragrant. The old Sweetbrier is a delightful plant for the wild garden. Often it has a half-weeping habit. There is some difference in the color of its flowers, which, in a wild state, range from nearly white to a clear pink. The finest Rose for color which has ever opened at Rose Brake is a Copper Austrian Brier now just out of bloom. It is curious to find a Rose with petals of scarlet velvet, almost the hue of a vivid scarlet Geranium. The blossoms seem on fire with their own beauty. This color is altogether unique among Roses. The foliage is very fragrant, something like that of the Sweetbrier, but more spicy. Our specimen is planted where it can scramble at will over a ledge of rocks, in company with such Roses

as *Rosa setigera* and Harrison's Yellow, the yellow Austrian Brier, the old Persian Yellow and others adapted for such a position, where Teas and even Hybrid Perpetuals would be out of place.

### Edible Wild Plants.

To the Editor of GARDEN AND FOREST:

Sir,—This is the season of "greens" and of more or less speculation on the edibility of wild plants. Looking over the list, and omitting the fruits of native plants as well as the bark of the Birch and the Sassafras, the young growth of the Beech-nut and one or two species of *Allium*, all of which are eaten raw, if at all, the number left for cooking entire is remarkably small.

Besides, there is no little misconception of the wholesomeness of many well-known plants. A writer on wild flowers has published a volume in which the reader is warned against the poisonous qualities of the Trillium, and there are many less learned notions equally as erroneous, so that the seeker after herb-food is unnecessarily timid. There is nothing poisonous about the Trillium, as I can testify from personal use of it for greens, particularly *T. erectum* and *T. erythrocarpum*, both of which are esteemed by those who have eaten them. *T. grandiflorum* is, no doubt, quite as wholesome, but it did not happen to grow within the limit of my excursions for native plants in boyhood days.

Early "greens" gathered in the lowlands include the Cowslip, a common name for the Marsh Marigold, *Caltha palustris*, but, like most edible plants, it becomes tough and bitter when in full blossom, and it is therefore soon worthless. About the cities the Dandelion is the great dependence for greens, and no amount of attack with knives in cutting off the crown of the plant will kill it—as in case of the Burdock and many other tap-rooted plants—for the Dandelion root is too much of a root-stock not to sprout again.

Many plants of the Mustard family, which are related closely to the Mustard itself and the Cabbage, are good for greens. Turnip and Cabbage stumps are sometimes planted in spring for this purpose. Of the Borage family, the Comfrey makes good greens when gathered young. The common Adder's-tongue, *Erythronium Americanum*, is sometimes used, and one or two species of Nettle, gathered with gloves, come into the list. Milkweed, treated much after the fashion of Asparagus, is esteemed where it grows in plenty.

Of weeds in cultivated grounds the narrow-leaved Dock, *Rumex crispus*, is used, but its neighbor, the Yellow Dock, *R. obtusifolius*, though much resembling it, is rejected. The common "Pusley," *Portulaca oleracea*, would also come into the list but for the fact that its stems, even after they are cooked, suggest angle-worms too vividly. There is a species of Amaranth common as a rampant weed in gardens where it obtains a foothold, sometimes known as Red-root, *Amaranthus retroflexus*, that is closely enough allied to the Beet and to Spinach to approach their high standard for greens. It must be used young, before the root becomes woody. The tall Pigweed, or Lamb's-quarters, *Chenopodium album*, is eaten, but its mealiness is not always relished.

Potato tops may be used in connection with other plants, but, as a rule, the *Solanum* family is too close to the line of poisonous plants to be eaten in the wild state. There is an innocent plant which, where it is plentiful, furnishes all the requisite qualities for greens. This is *Hydrophyllum Virginicum*, sometimes known as Boston Cabbage. It grows rampantly and usually forms a mass of broadly pinnate leaves. Coming up early, it will reappear after being picked off, and it does not become woody or bitter for a long time. As it takes full possession of the ground when given the opportunity, and is in no sense a weed, it seems that it might be introduced into semi-cultivation with profit, choosing a moist and partly shady spot.

### The Nomenclature of Abies.

To the Editor of GARDEN AND FOREST:

Sir,—Professor Greene (*GARDEN AND FOREST*, vol. x., p. 188) thinks that I overlooked some important considerations in my discussion of the nomenclature of the White Spruce. As a matter of fact, these considerations had presented themselves to my mind, but not attributing any very great importance to them I refrained from bringing them into the discussion. A binomial, or species, is published, according to the Rochester code, either by citing one or more binomials, with the name

of the author, publication, date, etc., as synonyms, or by giving a proper diagnosis in some scientific or other publication. In 1739 Gronovius published a flora of Virginia, in which he described an *Abies foliis solitaris* . . . membranaceis. So far as I am aware, all subsequent authors have considered that Gronovius had in view and described the Hemlock. In 1760 Miller described an *Abies foliis piceæ* . . . laxis (*Icones*, i., t. 1); there is no question but that Miller described, as he intended to, one of the Spruces other than the Hemlock. In the *Species Plantarum*, in 1763, Linnæus published a *Pinus Canadensis*, with the diagnosis *P. foliis* . . . submembranaceis, and quoting as first synonym the Gronovian description, Linnæus thinking (though erroneously) that Miller's species was the same, cited the latter's description as a second synonym. Professor Greene suggests that the Linnæan and Gronovian descriptions, which, at any rate, are synonymous, may not mean anything other than the White Spruce, but it is not likely that authors have since their time been so uniformly mistaken in interpreting their meaning. A reference to the Gronovian and Linnæan herbaria may throw some light upon this question, however. Miller in 1768 described an *Abies Canadensis*, using the Linnæan diagnosis, and quoting his own earlier description. Three things, then, are evident: that Gronovius and Linnæus had in view and described the Hemlock; that Linnæus erroneously thought that Miller's plant was the same as the Gronovian, and therefore that two species entered into the make-up of his *Pinus Canadensis*, which was founded primarily upon the Gronovian description—the Hemlock; that Miller followed Linnæus in thinking that his plant and the Gronovian were one and the same, but differed from Linnæus in having in view one of the Spruces instead of the Hemlock. Now, regardless of the fact that Linnæus had the Hemlock in view for his *Pinus Canadensis*, and that Miller had in view one of the Spruces for his *Abies Canadensis*, the two names must be considered according to the Rochester code as synonymous, since the diagnosis and synonymy in both are the same.

### Recent Publications.

*The Plant World. Its Romances and Realities.* Compiled and edited by Frank Vincent, M.A. New York: D. Appleton & Co.

This is one of the series of books which has been prepared under the supervision of W. T. Harris, United States Commissioner of Education, to furnish systematic home reading on natural history and other subjects. The books are prepared to carry out the University Extension idea and furnish opportunities for self-cultivation after school days are over, and this one, devoted to botanical subjects, can be used as a school reader. Of course, there cannot be much systematic science included in the fifty disconnected extracts found in this little volume, but they are all on interesting subjects, they are usually prepared by competent hands, and they certainly have the charm of variety. We have no reason to expect that the study of botany or any other science will receive any essential impulse from efforts of this sort. The real beginning of the study of nature comes from direct observation of natural objects. Nevertheless, books like this present in an interesting way many facts which ought to be known to persons of ordinary cultivation. It is a good thing for any young person to know something about the distribution of Ferns, the uses of the Coconut-tree, the Bread-fruit-tree and the Bamboo, and to get some idea of the botanic garden at Paradenza and the Cinnamon gardens of Ceylon. These are some of the topics treated in this collection, while among the selections which seem to have been arranged by chance are sprinkled short poems by Shelley, Longfellow, Whittier, Thomson and others. An editor thoroughly conversant with the literature of botany might have made a hundred books of this size, each one as good or better than this, and we should have liked this better if our *Sequoia* did not appear in it under the name of *Wellingtonia*. The illustrations are suggestive and helpful, and the frontispiece shows an avenue of Royal Palms in Rio Janeiro which in a striking way sets forth the value of these remarkable trees for what may be termed architectural planting.

### Notes.

At the beginning of a useful bulletin on spray-pumps and spraying, just issued by the New York Experiment Station, is the following important notice: Do not spray trees and plants when in bloom. It is in no instance necessary or desirable. Not only is this practice liable to injure the delicate parts of the flower, but, what is even more important, it poisons the bees and other insects that are our friends. It would be impossible to grow some of our fruits in commercial quantities without the aid of insects in fertilizing the blossoms.

One of the latest bulletins of the Cornell Experiment Station has been prepared by C. E. Hunn and Professor Bailey on Strawberries under Glass. After quoting a note from this journal to the effect that pots of Strawberry plants in fruit were among the specialties for sale on Broadway at Easter, the writers of the bulletin add that nothing in their experience has ever aroused so much enthusiasm from plant lovers as forced strawberries, and that it is difficult to conceive of anything better suited to table decoration than a clean pot with a thrifty, well-formed Strawberry plant bearing from six to eight full ripe berries and a few blossoms.

Like many other flowering plants, *Hemerocallis flava* has been unusually handsome this year. The Pæonies, Oriental Poppies, German Irises and other tall plants with large flowers which bloom about the first of June have never been more showy. By the way, *The Gardeners' Chronicle* of June 5th speaks of a hybrid between *Hemerocallis flava* and *H. Middendorffii*, which has appeared in the garden of our correspondent, Dr. Christ, of Basle. The resemblance of the hybrid to the latter plant is shown in its shorter flower-stalk and in the color of the flower, while in its inflorescence and the length of the tube it more closely resembles *H. flava*.

By long cultivation and crossing the Mock Oranges have assumed a great variety of form. Some of them belonging to the group of which *Philadelphus coronarius* is the best known, are more beautiful than the type, with much larger flowers and an odor which is not so oppressively sweet. These have all passed their bloom in this latitude, and *P. Zeyheri* is just coming into flower. It is an old shrub, quite distinct from the rest of the genus, and was distributed in America many years ago by the Messrs. Parsons, of Flushing, Long Island. It has smaller and more scattered leaves, arching branches six or eight feet high, and flowers with narrow pointed petals, which are star-shaped when looked at directly in front, although their general outlines are somewhat like those of a bell. It is altogether a pleasing addition to the shrubbery, and could hardly be spared even in this season of abundant flowers.

*Clematis crispa*, which is a native of the river-bottoms and swamps of our southern states, is already opening its fragrant lilac-purple cylindrical flowers, and it will continue to produce them until they are killed by heavy frosts in November. These flowers are not as showy as those of *C. coccinea*, which are longer, vase-shaped and bright pink, deepening toward scarlet. In spite of the fact that it is a native of Texas, *C. coccinea* is quite hardy in New England. Both of these plants have a long period of bloom and both bloom very late in autumn, in spite of their southern origin. Last year we noticed two or three rods of fence covered with these vines mingled together, and the effect was very pleasing. *C. coccinea* has rather sparse foliage, but this defect was remedied by the abundant leaves of *C. crispa*. A screen covered with these two vines would make an interesting display of foliage and flowers every day for four or five consecutive months.

Mr. A. H. Kirkland, who has been assisting Dr. Fernald, of the Gipsy Moth Committee, has prepared a paper on the habits and food of the American toad, which has just been published as a bulletin by the Hatch Experiment Station, at Amherst, Massachusetts. After an introduction, in which the ancient ideas as to the venomous qualities of this animal are set forth in a very readable manner, Mr. Kirkland gives statistics which show that only eleven per cent. of the toad's food is composed of insects and spiders which are beneficial or indirectly helpful to man, while eighty per cent. of its food consists of insects and other animals directly injurious to cultivated crops or in other ways obnoxious to man. This shows a record which will compare favorably with that of any of our insectivorous birds, and it is suggested that the boys, who are its most continuous persecutors, should be instructed as to its habits and that laws should be enacted to arrest its wanton destruction.

Receipts of apples are becoming light, and last week was the first of the season in which none have been shipped abroad

from this port. Northern Spies, from this state, are the choicest apples now seen in the local markets, with Ben Davis, Roxbury and Golden Russets. Pears are already included in the new-crop fruits now in season, and the first Le Contes have arrived from Florida. Botan and Chickasaw plums are also coming from the same state, and the first Alexander peaches arrived from California last week, with the same variety from the southern Atlantic states. Cherries are plentiful from near-by points, and those from California, larger and of preferable quality, have been exceptionally cheap, owing to dull business during the rainy weather of early June. Strawberries of all grades may be had from Maryland, Delaware, New Jersey, Staten Island and the Hudson River section in this state. Gandy's Prize is one of the best sorts. No more handsome berries than those now coming from Hilton, New Jersey, have ever been seen here. Besides other field and garden fruits from the southern states, there are still some Valencia oranges from California, with the first cherry plums and apricots. Twenty-six car-loads of California fruit were sold here last week, mostly cherries and apricots.

Mr. W. R. Dodson, the Botanist of the Louisiana Experiment Station, has been examining the tubercles on the roots of leguminous plants by means of which nitrogen is taken from the air and used as a food material for the plants. The experiment seems to indicate that each plant, or at most each genus of plants, will support only one kind of parasitic organism capable of developing root tubercles. For instance, a particular organism must be present in the soil if tubercles are formed on Alfalfa, and any quantity of Cow Peas or other leguminous plants will not furnish the proper form of life. The Cow Pea likewise has its peculiar parasite, and dozens of leguminous plants may be grown side by side and each develop its own specific tubercle. Nevertheless, several imported species have been grown and formed tubercles, although the plants were not found in this country and have never been grown in the soil, which seems to indicate that the organism must have been in the soil before the seeds were planted, as there could have been no inoculation from soil in which the plant had been previously grown. If this is true, the organisms are not dependent on any particular plant for their existence, although the plant may be dependent upon them for its fullest development. Their absence from some soils and presence in others cannot, therefore, be explained satisfactorily. While the tubercles have peculiarities of shape or appearance they do not present characteristics that enable one to distinguish them under the microscope, although there are probably as many varieties as there are species of leguminous plants. The fact is that much is to be learned on this important subject before farmers can inoculate their soils with the assurance of success with any given crop.

An interesting bulletin in popular form has just been issued by the Geneva Experiment Station of this state in relation to Gooseberries. There are two native American species, *Ribes cynosbati*, with prickly fruit, and *R. occycanthoides*, with smooth fruit. The European Gooseberries, *R. grossularia*, have been cultivated for generations, and, at least, a great number of varieties of this species are being tested at Geneva. These bear large and beautiful fruit, but the plants are so liable to mildew in this country that unless this can be checked they are of little value. Many of them bear fruit an inch and a half long and an inch or more in diameter, while the fruit of the native varieties is smaller and less varied in color. In quality the best American sorts are superior to the foreign kinds, since they have thinner skin and a more delicate flavor, and in spite of the smallness of the fruit they are more productive than the foreign varieties. Downing, Houghton, Crystal and Red Jacket are among the best of the American sorts. The well-known mildew is a fungus which grows on the surface of the green shoots, the foliage and the fruit, at first frost-like, and covering later the affected parts with brown or black felt-like patches. To check this fungus the plant should be set in well-drained soil in high locations where the free circulation of air is not hindered by tight fences or wind-breaks of any kind, so that rapid evaporation of dew will be secured. Shallow cultivation, keeping the soil light and free from weeds, and pruning to admit air currents are also essential. The Bordeaux mixture is liable to spot the fruit, and it is, therefore, better to spray the bushes as soon as the buds begin to open with potassium sulphide in a solution of one pound of sulphide to thirty-two gallons of water. If one is prepared to make a determined fight against the mildew in this way he can successfully raise European sorts like Industry, Crown Bob and Wellington Glory, and secure fruit both early and late of striking size and color.

## The Park System of Greater Boston.

WE have several times made allusion to the Metropolitan Park System, which includes public holdings in various cities and towns within a radius of twelve miles from the Boston State House. Under an act of the Massachusetts Legislature passed in 1893 a Board was appointed to take charge of this system in the thirty-seven cities and towns which make up what is known as the Metropolitan District. Outside of the parks of Boston proper this Commission now has charge of about 6,800 acres of land, and the appropriations thus far made for the use of the Board have amounted to \$4,300,000. The annual reports of the Metropolitan Park Commission have always had a genuine educational value, as they give an account of the first intelligent effort at providing a comprehensive and consistent park system for so large an area, with its separate reservations under different governments, and covering a territory which will soon be densely populated. These different pleasure-grounds are judiciously distributed from the great Middlesex Fells and Lynn Woods Reservation on the north, down through the Fens, Franklin Park and the Arnold Arboretum, to the 4,000 acres of the Blue Hills on the south, and from the magnificent stretch of Revere Beach, which fronts the open sea, to the unique water parkway into which it is proposed to convert the Charles River, stretching out to the west. These reservations are not only connected with the populous centre of the district by cheap and rapid means of transportation by electric cars, but stately parkways will provide dignified approaches to the larger pleasure-grounds and make them agreeably accessible to those who do not choose to take a public conveyance.

In the report lately issued it is a pleasure to note that the Commission holds to the same high purpose, primarily insisting that the foundation work for the future shall be broad-set and firm, and not making any nervous haste for immediate effect. Here is one great undertaking in which nothing is left to chance. No detail is attacked in a desultory or unrelated way or until there is a general design which will enable those who are entrusted with its development to work with a definite purpose at every point and all the time. A moment's reflection will convince

any one that this is the only common-sense way of treating such a work, and yet we believe the Metropolitan Park System of Boston is unique in that not only the original selection of the reservations, but the adjustment of their boundaries and the choice of routes for parkways to connect them, have been matters of design. It may be added that no detail of construction is begun in any one of the reservations until the same close study has been made of its interior features as has been given to the general scheme. In nine cases out of ten the designers of public parks find that some city has come into possession of a certain number of acres of land by some chance, and then this land is modeled or planned without any particular relation to other pleasure-grounds or to the means of reaching them. In this city, for instance, we have half a dozen so-called parks lying north of the Harlem River, ranging in area from seventeen hundred acres to a hundred in size. No intelligent study of their boundaries has been made. Some of these come within a few feet of an existing street, but leave a narrow strip of land between the park and the roadway. There is little doubt that in any one of them a skilled designer could point out how the possession of a few acres outside of the line would be invaluable for completing a picture or furnishing some desirable feature, and how a certain area in another place might be surrendered with little loss and sold. In Bronx Park, plans have already been prepared for a botanical garden and for a zoölogical garden, without any suggestions as to the revision of the limits of the park, and without any adequate study of its approaches or surroundings. We may add that these so-called parks above the Harlem have not even been surveyed, while new roads are being built all about them without any thought of their relation to the parks, and many of the parks themselves are cut by roads for traffic and thus needlessly turned over to business when they might as well have been made pleasure-grounds pure and simple.

No doubt, the Park Commissioners of Greater Boston are right when they say that the reservations already acquired are a distinct addition to the resources of the commonwealth, and that considered as salable assets to-day they are worth more than they have cost. No doubt, too, they have a higher value than this in the renown they bring to Metropolitan Boston, and in the health and pleasure they will give to its future population. Beyond question, this pleasure is greater because the new park system is the result of study and not of chance, and it seems a thousand pities that other cities will go on acquiring costly lands and then allow them to fail of their highest purpose by neglecting to treat them as they do any other great work. As to the necessity of a careful study which not only includes the topography, but the different kinds of vegetation in all its parts before any roads are built or spaces are cleared, the landscape-architects say:

To us it seems that a due regard for the high purpose of public reservations, as well as a due regard for the economical fulfillment of that purpose, prohibits piecemeal, unrelated and hand-to-mouth work in such domains, precisely as it prohibits planless and disconnected work for the accomplishment of any and every large purpose that can be imagined—for the purpose of sewerage and water commissions, or trustees of art museums and public libraries, for example. Park commissions are the trustees of the people's treasures of scenery; they are responsible for the safeguarding and the increase of this treasure, and they are charged with the duty of making it most effectively accessible. Being trustees they cannot safely proceed planlessly any more than can they who are charged with guarding and making accessible the people's treasure of books and pictures, or with providing the people's drinking water. The devising of comprehensive and far-seeing plans or programmes of procedure is for park commissions as well as for all other executive bodies the most necessary, arduous and responsible labor which they are called upon to perform.

It is clear that if the natural beauty of any place is to be preserved and its poetic charm is to be enhanced, while at the same time it is made accessible to thousands of visitors every day, this is the one thing that requires the

most considerate and prophetic planning. Leaving a reservation alone is to encourage monotony and obliterate scenery, and if there is to be any enrichment of the landscape beauty of a place there must be a programme of work devised which looks specially toward the controlling and directing of its vegetation. Fortunately, the two great reservations, Middlesex Fells and the Blue Hills, are wild picturesque lands which for the present need little more than forest treatment. If the energies of the Commissioners for a score of years to come are directed to the work of restoring and improving these woods they will not only be constantly increasing in beauty, but they will make an object-lesson of great value to the entire country. Of course, all this is to be done with intelligent attention to lines of permanent roads to come and of the points of view which command choice stretches of scenery. This means the recognition in a broad way of all the essentials of the landscape until more elaborate and detailed plans are needed. We do not invite attention to this work of the Commission because it is novel in theory, or because any intelligent person will think of disputing its soundness, but because in practice it is constantly violated, greatly to the increase of the cost of constructing and maintaining pleasure-grounds, and to the diminution of their actual value.

#### Private Forestry and State Forestry.—II.

NOW, let us imagine that a tract of Michigan White Pine forest is suddenly transported by some unknown agency into the heart of Germany, say, to the neighborhood of Dresden, and let us further imagine a capable, well-informed forester in charge of it. What is the forester likely to do with it? Will he remove in each year from the entire tract no more timber than the annual increment allows, so as not to reduce the specific quantity of timber which constitutes the entire growing stock? Will he cut only trees of mature age likely to die if not felled? No. The forest administration would proceed in much the same way of the Michigan lumberman. It would not allow a large capital to lie idle, bearing very small interest, but would convert the timber into money as soon as possible, establishing at the same time, by skillful cutting of the trees, a second growth consisting of seedlings and trees of pole size, the annual increment of which is sufficient to pay ample interest on the capital which they represent. The woods would not be entirely cleared in a single year, simply because it would not pay well. The seedling growth left on the ground by the method of successive cutting has a value which more than covers the extra expense for successive cuttings, when these are carefully made in a way to avoid injuring the second growth. Of course, such seedlings are not valued for the timber they actually contain, but because they will ultimately produce timber. German foresters know that a piece of woodland which in twenty-five years will contain 5,000 feet, worth \$30.00, is now worth \$8.86,\* and, after harvesting that, there will be another crop worth then about \$8.86, and worth now \$2.62.

The financial principle, of course, holds good for America as well as for Germany, and, if only the circumstances were the same, the lumberman would do exactly as the German forester does. The American lumberman, if he cut the tree crop carefully, would certainly succeed in establishing a second growth consisting of seedlings and small trees; from the annual increment of the second growth a reasonable interest might be derived on the extra expense of careful cutting and on the capital value of small trees left standing. But if the lumberman succeeds in doing that he is not at all sure that the second growth on a certain area will develop into \$30.00 worth of timber within twenty-five years, and no one would give him \$8.86 in exchange for it, because it is much more likely that the entire second

growth will be eaten up by fire\* than that it will reach timber size within the next twenty-five years. Abroad, where forest fires are practically unknown, money invested in timber production is considered safer than if invested in Government bonds, and for this reason three per cent. per annum on the forest capital is considered an ample return. In this country no one would think of investing money in growing timber, because, owing to the slow growth of trees, he could not net more than three per cent. per annum on his capital. If tree-growing should pay under favorable circumstances ten per cent. or more, then the lumberman† would be more likely to stand the risk of fires.

If there were no fires, and therefore no danger of loss of capital, the lumberman, like any other capitalist, would be satisfied with comparatively low interest, and, like the German forester, would provide for a future crop while harvesting the present crop. In fact, there is no difference between forestry and lumbering; both try to make as much money out of the wood as possible. And as long as ruthless clearing pays ultimately better than any other method, ruthless clearing is the course to adopt from the financial standpoint of forestry. This sounds paradoxical, as Americans are in the habit of considering forestry to be the art of cultivating, using and preserving forests. Such an art, however, is not financial forestry, but merely the development of the principle of forestry under a certain set of circumstances. Where cultivating, using and preserving forests yields the highest money result, as it does abroad, there cultivating, using and preserving forests is economic forestry. Where making a clean sweep yields the highest results, as it has hitherto done in the United States, there making a clean sweep is economic forestry. In a very densely wooded but thinly populated country far away from large markets, as long as the world lasts, mere lumbering will be the consequence of the true principles of forestry. In fact, in such a country ruthless lumbering and forestry are identical. Mr. J. E. Defebaugh, editor of *The Timberman*, Chicago, Illinois, in an interesting address delivered before the World's Fair Congress, comes to the conclusion above indicated, stating, "It is not within the power of the lumberman, under present conditions, to carry out any policy of forest preservation or culture."‡

Now, if the present conditions do not allow economic forestry to preserve forests, and if it is, on the other hand, a vital interest of the state to have the forests preserved, then the conditions must be changed by the state. To compel the lumberman by stringent laws to cut only mature timber, to clean up the debris, to replant the areas cleared, is utterly impracticable.

The change of conditions needed is mainly protection from forest fires by laws strictly enforced by the Government. Protection from forest fires is the essential condition that renders forest preservation and forest regeneration remunerative. With the certainty of their being safe from fire in the future, seedlings and young trees have a value. Now, if it is true that the commonwealth needs forests, then the commonwealth must pay for the change of conditions for the protection of young woods from fire. The owner of the forest, when practically sure that fires will no longer occur, realizes at once that a second growth left on the ground has a value; he will find out that forest preservation and forest regeneration pays, and will therefore try to preserve and regulate his woodlands.

Reduction of taxes on second-growth woodland when

\* Besides by fire, young trees are endangered by wind, insects and fungi. However, checking insects and fungi is comparatively easy if the fires are stopped, and wind-breaks can be lessened under proper management.

† The term "lumberman" in the above remarks designates the forest-owner in his capacity of lumberman. The lumberman who buys stumpage from the owner, of course, has not the slightest interest in the preservation or regeneration of forests, neither here nor abroad.

‡ Mr. Defebaugh gives a financial illustration of what he thinks to be forestry. A virgin forest of 100,000 acres of Pine, he assumes, under forest methods, yields 20,000,000 feet per year with a growing stock of 700,000,000. But such forest methods are far from being economic. I would cut, say, 45,000,000 feet annually during fourteen years, thus reducing the investment of capital to a minimum and raising a second growth at the same time, from which, after the lapse of the fourteen years, 20,000,000 feet may be cut annually. An average production of 200 feet per acre per annum with White Pine, if the rotation is fifty to eighty years, is certainly not too high. Compare *Proceedings American Forestry Ass.*, vol. x., page 155.

\* These figures are merely meant for illustration, and are not based on any actual data. For the calculation compound interest at five per cent. was taken.

sufficiently stocked might form another inducement toward forest preservation. Here, again, if the state benefits by the existence of woods, it should reward the men who preserve them by refunding or reducing taxes. Such laws will constitute the most important step possible against further decrease of the timbered area. The maintenance of the forest-clad area, in consequence of forest fire and tax legislation, will not, however, do away with the evils already existing. It will not restore the millions of acres which are not only unproductive, but a constant and increasing danger to the lowlands, having lost their capacity of storing up the precipitations, of mitigating atmospheric extremes and conferring health on the neighboring population. There are also vast districts, now more or less heavily timbered, whose mere existence is so beneficial that neither the lumberman nor the forester should be allowed to cut them, as young seedling growth does not act as beneficially on climate, water-supply, etc., as mature woods do. With such forests, found at the headwaters of streams or near large cities, the principles of economic forestry do not hold good, because their value in the economy of mankind is less than their value in the economy of nature. Such forests must be withdrawn from a merely financial treatment, for the sake of the commonwealth. Withdrawal from the usual economic treatment being identical with the withdrawal from ownership by private individuals, their acquisition by the public becomes a necessity.

It would, of course, be absurd to dispense entirely and invariably with the economic use of areas called forest reserves or reservations in America. But, while financial forestry manages the forests with the exclusive view of securing the greatest money return, reservations are meant, in the first instance, to furnish prosperity to the commonwealth or to parts of it, and only such financial profits are expected to be derived from them as are consistent with their main purpose of existence—health-supply, water-supply, protection of lowlands from destruction or deterioration. The value of health, water and protection secured to the commonwealth by forest reservations cannot be exactly measured and expressed in dollars and cents. We may estimate it, however, by calculating what loss the community would incur if it were less healthy, more subject to sudden changes of temperature, possessed of fewer opportunities of refreshment from outdoor life; or, again, what loss the community would suffer from an inadequate supply of water for domestic use, irrigation and navigation; from the destruction of bridges and roads and railroads, farm-lands, houses and human lives by inundations and floods. The principal return from forest reservations is not shown in money gained, but in losses avoided. If the sum of the losses which a given community would annually undergo in consequence of the ruin of a reservation is estimated at \$4,000,000, then the value of the reservation is about \$100,000,000.

Every reservation, apart from its value as a barrier against possible losses, has a value as a source of money returns from the sale of timber, etc. True forest management, in the case of reservations, is that which renders the value of the "barrier against losses" plus the value of the "source of revenue" a maximum. The more a tract of woodland has the quality of a reservation the less will forest management regard strict economic principles in its treatment, and the more necessary becomes its acquisition by the community interested in it.

## Foreign Correspondence.

### London Letter.

**CRINUM SCHIMPERI.**—This plant is thriving out-of-doors at Kew under the same conditions as *Crinum Mooreanum*, *C. longiflorum* and the hybrid *C. Powellii*. It may, therefore, be looked upon as another addition to hardy *Crinums*, and as it is a well-marked species with glaucous subdis-

tichous leaves and tall scapes of handsome white flowers, it is likely to become a popular garden plant. It was introduced about ten years ago from the mountains of Abyssinia, where it was first gathered by Schimper, who also found *C. Abyssinicum*, with which *C. Schimperii* was confounded. It is figured in *The Botanical Magazine*, t. 7417. Another species of *Crinum* which has been tested for its hardiness at Kew is *C. Americanum*, a native of the southern United States, but it is too tender for our climate, even when planted in a sheltered position against the south wall of a greenhouse.

**LATHYRUS SPLENDENS.**—We are delighted with this, the "Pride of California," which has been a beautiful picture of flowers for the last two months and promises to continue in bloom well into the summer. It is as beautiful as any *Pea* I know, as floriferous as a *Scarlet-runner* and as easy to manage when once its requirements are understood. We have it planted in a bed of loam in a sunny, airy greenhouse, with its shoots at first trained on strings within a foot of the roof. The training has, however, ceased and the new luxuriant growth straggles and festoons in all directions, while from every leaf-axil springs an elegant raceme of from four to eight deep crimson flowers. A peculiarity of this species is the production of one or a pair of flowers at the base of the stalk of the raceme, and almost sessile in the axils of the leaves. It is likely to become a popular greenhouse climber now that its merits have been revealed here and its requirements have been hit upon. For the last five years we have tried to grow it in the open air, and have always failed.

**RHODODENDRON, MADAME MOSER.**—I omitted this new plant from my notes of last week. It is a double-flowered variety of the *Caucasicum* × *arboreum* group, and is apparently dwarf and floriferous. The color of the flowers is deep crimson. This variety is interesting mainly on account of its being the second double-flowered variety of this class of *Rhododendron*, the other being *fastigiata flore-plena*, which is a seedling form of *R. Ponticum*. It is questionable if doubling the flowers of *Rhododendron* would be an improvement, although the double varieties of Indian *Azaleas* are beautiful as *Carnations*. At any rate, the doubling has started, and, no doubt, before long we shall see more of it. The variety under notice has been raised by Monsieur Moser, of Versailles, and it has been awarded a certificate by the Royal Horticultural Society.

**OLEARIA MACRODONTA.**—While the majority of the New Zealand Daisy-bushes are too tender to bear our severest frosts, several are useful shrubs for outdoor cultivation, *Olearia Haastii* being the most familiar. One of the most distinct and handsome is *O. macrodonta*, which forms a robust shrub in the open and also grows well against a wall. It has woody striate brown stems, freely branched and clothed with evergreen oblong gray-green leaves, silvery on the under side, the margins broken into large irregular teeth; in size and outline they are very similar to those of the common *Holly*. The flowers are borne on short branches in crowded terminal heads six inches in diameter, each flower being half an inch across, pure white, with purplish disk. The Kew plant is now flowering freely. It used to be called *O. dentata*. A figure of it was published in *The Botanical Magazine*, t. 7065.

**PHILADELPHUS MEXICANUS.**—Although introduced into English gardens more than fifty years ago, this plant has found little favor, probably because of its tenderness compared with the other and more commonly grown species. At Kew it is perfectly happy against the south wall of a greenhouse, and for the past month it has been flowering freely, its fragrant, creamy white, saucer-shaped flowers, nearly two inches across, occurring singly at the ends of the short lateral branchlets, while the leaves are dark green and shining, ovate lanceolate, two inches long, the three principal nerves very conspicuous and the margins dentate. The plant is first-rate in every sense when grown as here described, and I have no doubt that it would prove useful for cultivation in cool houses in the

same way as the *Carpenteria* here noted. It is by far the largest-flowered of all the species of *Philadelphus* in cultivation here.

*DENDROMECON RIGIDUM*.—We make poor progress with this plant, which is described as a handsome shrub in California and very floriferous. We have it planted against a south wall, a less-sheltered position being uncongenial, but it grows slowly, and is decidedly thin, "a weedy, wiry-looking object," Mr. Gumbleton called it. This gentleman is of opinion that we have not got the true *Dendromecon rigidum*. The flowers are of a rich yellow color, about an inch in diameter and Poppy-like, or, to be exact, like those of the Welsh Poppy, *Meconopsis Cambrica*. Possibly our plants are too small to judge by—they are at present about a foot high—but they have been flowering freely for the past month or more. When discovered by D. Douglas in California, about forty years ago, it was introduced and grown by Messrs. Veitch in their Exeter nursery, where it proved quite hardy. A figure prepared from this introduction represents it as a sturdy bush with straw-colored branches, rigid, lanceolate entire leaves three inches long and flowers two inches across. Are two forms of this species known?

[There is a second species of *Dendromecon*, *D. Horsfordii*, a stout bush, sometimes fifteen feet high, with oval or broadly oblong obtuse leaves and larger flowers. This grows on the California Islands, and is a handsomer plant than the mainland *D. rigidum*, which is always unattractive in habit, with slender erect wiry stems, and hardly worth growing, except as a curiosity.—Ed.]

*CARPENTERIA CALIFORNICA*.—This plant is not a success in the open air at Kew, and I learn that even in the south of Ireland it does not thrive outside, the leaves turning partially brown and the flowers coming deformed and irregular. But grown under glass it has proved quite satisfactory. In a conservatory at Kew there is a pyramid-shaped shrub of it six feet high with healthy leaves and bearing numerous erect racemes of the purest white saucer-shaped flowers. Mr. Bennett-Poë also grows this plant successfully by planting it in tubs and placing it outside in the summer, removing it into a vinery and keeping it fairly dry on the approach of cold weather. It is one of the most beautiful shrubs we owe to the United States, and that is saying a great deal, but it requires the protection of a greenhouse during winter, and its flowers only come perfect when opened under glass.

*MAGNOLIA FUSCATA*.—Although comparatively small and dull-colored in its flowers, this Chinese *Magnolia* has long been grown as a garden plant on account of its powerful and delicious fragrance. There is a large bush of it in the large temperate house at Kew, which is nearly always in flower, scenting the whole house at times. A plant is also established on a south-east wall outside, having been there about three years, and it grows and flowers so freely that one begins to wonder if it is not a hardy shrub, after all. At any rate, it is worth a position on such a wall as that described, the odor of its flowers being particularly pleasing. It has withstood all the frost we have had during the last two years, so that one may gauge its hardiness as equal to a minimum temperature of about twenty degrees, Fahrenheit.

London.

## New or Little-known Plants.

### *Robinsonella*, a New Genus of Tree Mallows.\*

THE recent collections of Mexican and Central American plants are full of little-known and new species, and even new genera are not uncommon. It is rare, however, to discover a genus of trees, and especially one as attractive as this one.†

\* Published by permission of the Secretary, Smithsonian Institution.

† *Robinsonella* Rose & Baker fil., gen. nov. Bractlets at base of calyx, none. Calyx 5-cleft or lobed. Stamens united into a slender column, divided at apex into numerous filaments. Cells of ovary 9 to 13, 2-ovuled; style branches filiform; stigmas capitate. Ovule solitary, hanging; mature carpels much inflated and

In Mr. E. W. Nelson's last collection and the recent distributions of Mr. C. G. Pringle and Captain John Donnell Smith are two undescribed species which, with one heretofore anomalous species generally referred to *Sida*, seem to constitute a new generic type. The species are all small trees or shrubs with large and palmately lobed or veined leaves and large white or pale lilac-colored flowers. Some of the species are very handsome and worthy of cultivation, but since all come from southern countries they can hardly be used outside of greenhouses, although one of them, and perhaps the handsomest, comes from the mountains about Oaxaca, where it was found at an altitude of 7,500 feet.

This new genus belongs to the Mallow family. Its technical characters place it in the subtribe *Sidæe* and near the genus *Sida*, from the typical species of which it differs in habit, in color and size of flowers, and especially in the character of its carpels.

The differences in the carpels are several and very important. While in both genera the ovules are solitary and pendulous in the young carpels, in the new genus the upper part of the carpel rapidly develops, leaving the seed at the base, which thus appears as if it originated at the base, and in, at least, one of the species the attachment is so low that the free end of the seed is pushed up and becomes erect. The carpels are much inflated, of thin papery texture throughout, never reticulated, obtuse at apex, and do not in the least suggest a *Sida*. They are tardily dehiscent, seeming to split from the base up along the back; the seed often hangs by a slender thread which runs along its back the full length of the carpel. The calyx is much smaller than the fruit, the sepals never connivent or enclosing it, as in *Sida*, but more or less open, or even reflexed.

The genus as we now understand it is composed of five species, two of which are Mexican, one Central American and two South American.

We take pleasure in dedicating this genus to Dr. B. L. Robinson, the Curator of the Gray Herbarium, whose contributions to American botany deserve to be commemorated in this beautiful genus of Tree Mallows. The species as we understand them are the following:

*Robinsonella cordata*.\* (See figure 31, page 246). The collection of this tree by both Mr. Nelson and Mr. Pringle in 1895 first led to our recognizing the new genus. The species is, perhaps, the handsomest of the group. It must, however, be very rare, which, perhaps, accounts for its having been overlooked by previous collectors. Mr. Pringle wrote, under date of March 15, 1897, as follows: "I saw only two plants. One was a shrubby plant on the rocky bluff of a cañon (and only seen from the railroad train), the other was the tree, about twenty-five feet high, from which I took specimens, then coming into flower. I got nothing to show the character of the fruit. I climbed into the top of this tree, and remember it as of upright habit with a trunk of about a foot. It cannot be abundant in the vicinity of Oaxaca, for I traveled thereabouts extensively and saw only the single specimen growing on the slope of the Sierra de San Felipe, some seven miles above that city."

spreading, united only at the base, obtuse at the apex, and perhaps tardily dehiscent; seed 1, attached near the bottom of the mature carpel, appearing as if coming from the base, and filling only a small part of it.

Shrubs or small trees. Leaves palmately lobed or veined. Flowers large, white or pale lilac.

\* *Robinsonella cordata*, Rose & Baker, sp. nov. Trees 15 to 25 feet high, much branched; branches with dark gray wrinkled bark, pubescent, tardily becoming glabrate; mature leaves broadly ovate with cordate base, simple, acuminate, 5 to 7 nerved, slightly crenate, nearly glabrous above, paler and softly pubescent beneath, 3 to 4 inches long, 1½ to 3 inches wide; petioles 1 to 1½ inches long, villous pubescent; flowers borne in the axils of the old leaves in small clusters of 3 to 5 on short peduncles; pedicels slender and weak, 5 to 10 lines long, jointed near the middle, clothed with short stellate pubescence and with longer simple hairs; calyx deeply 5-parted, densely stellate, with or without villous hairs; flowers 2 inches in diameter, pale lilac; styles 12 to 13; stigmas capitate; carpels 12 to 13, distinct nearly to the base, somewhat inflated, obtuse, thin, stellate, one-seeded; seed glabrous, filling but a small part of the carpel.

Collected by Mr. E. W. Nelson near Tamazulapam, State of Oaxaca, Mexico, altitude 6,500 to 7,000 feet, November 16, 1894 (No. 1955), and also by Mr. Pringle on the Sierra de San Felipe, altitude 7,500 feet, 1895 (No. 6244). Distributed as *Malva subflorosa*.

*Robinsonella divergens*.<sup>\*</sup> (See figure 32, page 247). This species is a small tree eighteen feet high. It will be found in many herbaria under the name of *Sida Lindeniana*, from which, however, it is wholly distinct. *R. divergens* is confined to Central America, and differs from the above in its leaves, flowers and carpels. It appears to be very common in Central America and Guatemala.

*Robinsonella Lindeniana*.<sup>†</sup> This species is described as a shrub, but we know very little regarding it. It seems to be confined to the low land of Mexico, being reported from the state of Vera Cruz and the valley of Cordova. It cannot be widely distributed, for Mr. Pringle, who has traveled so extensively in Mexico, has never met with it. It has been collected, however, by Linden, Galeotti, Bourgeau and Botteri. The specimens of the latter two collectors are represented in the United States National Herbarium. *R. Lindeniana* has always seemed to us to be anomalous in *Sida*. It was first studied by Turczaninow (in 1858), who described it under three different names in the same paper—twice as *Sida* and once as an *Abutilon*. The flowering specimens were referred to *Sida*, while the fruiting one was placed in *Abutilon*. The carpel much resembles those of *Abutilon*, but differs in having one ovule instead of several. Dr. Gray, in his revision of our United States species in 1887, constructed a separate section in *Sida* for this species in these words: "*Abutilastrum* is a name quite appropriate for another section, namely, for *Sida Lindeniana*, which would be essentially an *Abutilon* of the section *Gayoides*, except for the uniovulate carpels."

This view was taken by Mr. Baker in his recent Revision of *Malvaceæ* in the *Journal of Botany*, where he added several species to the section. A good illustration of this species may be found in Hemsley's *Biologia Centrali-Americana*, t. 9. It differs from *Robinsonella divergens* in having, perhaps, larger leaves, with the pubescence on the under surface very soft and villous, the inflorescence more open, with more slender and longer pedicels, the sepals broader, the flowers smaller and white instead of blue, and the carpels more compact, etc.

*Sida lepida* (*Fr. Muell. Frag.*, vi., p. 168), from Australia, differs in habit from the members of this genus; the leaves are small and orbicular, the structure of the carpels is, however, somewhat similar, being inflated, globose and one-seeded and the seed pendulous. It appears to be an ally of some of the globose-fruited species of *Abutilon*, such as *A. graveolens*, W. & A., differing, of course, technically in the number of ovules.

*Sida densiflora* (Hook. & Arn., *Bot. Misc.*, iii., 155) was first described from Borgia in the Missions, where it was collected by Baird. It is said to be a beautiful tree, and the type is in the Kew Herbarium. This plant is closely allied to *S. myriantha*, Pl. & Lind.; both species are much smaller-flowered than *Robinsonella cordata*, *R. divergens* and *R. Lindeniana*, and according to Dr. K. Schumann (*Fl. Brasil*, XII., pt. iii., p. 287) *S. densiflora* differs considerably from them in the structure of the carpels, while *S. myriantha*, Pl. & Lind., so far as we are aware, has not yet been collected in fruit.

Dr. Schumann, l. c., p. 280, makes a section of *Sida* for

*S. densiflora*, H. & A., calling it *Bastardiopsis* and characterizing it as follows: "Flores gynodioeci, i. e., plurimi post anthesin caduci; carpidia longe caudata, caudis flexuosis pilosis carpidiis pluries longioribus, dorso et ventre dehiscencia, contigua tardius soluta."

*Sida densiflora*, H. & A., differs from *S. myriantha*, Pl. & Lind., in having the calyx externally much more densely cinereo-tomentose and in having a much longer staminal column. It comes from Brazil (Minas Geraes and St. Paulo), and from Paraguay.

*Sida myriantha*, Planch. & Linden, ex. Tr. & Pl. in *Ann. Sc. Nat. Sér.*, iv., xvii. (1862), p. 179, comes from New Granada, the localities given by the authors being "Prov. Ocana. Schlim, No. 359" and "Onebrada de los Corales," Gondot. It is in the British Museum Herbarium, from Prov. Ocaña, Schlim, No. 376.

In our study of this genus we have had access to the material at Kew, in the Gray Herbarium and in Captain John Donnell Smith's Herbarium, as well as that of the British Museum, and in the United States National Herbarium.

J. N. Rose and E. G. Baker.

## Cultural Department.

### Chrysanthemum Notes.

CHRYSANTHEMUMS intended for specimen plants should be making rapid growth now, and stopping must be continued regularly; a shoot overgrown, and then topped, breaks badly. Varieties like Garza, W. H. Lincoln and Glory of the Pacific make good plants with little training. Others are difficult to manage, no matter how much care is used to get them into shape, and some of the choicest kinds are unruly in this respect. It is seldom, out of a dozen novelties, that more than one or two are found useful for bush specimens. New varieties may be tried, but they should not be relied upon; though the color and form of the flowers may be entirely satisfactory, the habit of the plant may be undesirable.

We continue stopping through the greater part of July, and even in August, if we find any shoots getting away. No rule can be made for either early or late varieties, and the cultivator must become acquainted with the different kinds to be able to judge in respect to stopping. Many early varieties break poorly; strong-growing and stocky varieties, as G. W. Childs and Minerva, almost always do so. As these generally make good-sized flowers on smaller stems, we continue to pinch them back until August. Others, such as Ivory, G. Daniels, Arethusa and W. H. Lincoln, are naturally bushy, and need little attention at any time. Later varieties, as John Shrimpton, S. T. Murdock and all those that come best on an intermediate bud, or second crown, like Crystallina, G. Pitcher, Golden Hair and Clinton Chapant, must be let alone after the middle of July.

Yellow thrips are more troublesome than usual. As a remedy I use whale-oil soap—one pound to ten gallons of water, with an infusion of tobacco and a pound of sulphur. This pest is hard to kill, but by continued application we expect to get rid of it. The soot of bituminous coal, used in place of sulphur, was effectively used.

Plants intended to be grown for exhibition blooms to a single stem should be planted during the month of June. July will be early enough to plant for commercial and decorative purposes. Not less than nine inches each way should be allowed for exhibition blooms. For decorative purposes and later planting six inches apart will do. The heights and colors of the flowers may be arranged to harmonize effectively.

Wellesley, Mass.

T. D. Hatfield.

### More June Irises.

THERE are other Iris species interesting in the garden in early June besides the Spanish varieties. The most stately one and among the tallest of Irises is *I. ochroleuca*, which flowers at a height of four feet. The blooms are pure white, with orange-yellow markings. The claws are long, falls obovate, and standards not very prominent. Each stem usually bears four flowers opening in succession. This Iris is also grown as *I. gigantea*, but according to precedence it should be known as *I. orientalis*. *I. Kerneriana*, collected near Smyrna, for which I am indebted to Mr. Whittall, is supposed to be the wild form of *I. ochroleuca*, and differs from this well-known Iris only in being narrower in all its parts, the leaves as well

\* *Robinsonella divergens*, Baker & Rose, sp. nov. A small tree 18 feet high; lower leaves 3-lobed, 6 to 8 inches long, including the petiole (2 to 3 inches long), acute, serrate, cordate at base; upper leaves lanceolate, simple, slightly serrate or entire, somewhat scabrous above, short stellate-pubescent beneath; inflorescence cymose-paniculate; pedicels short, 2 to 6 lines long; calyx deeply 5-cleft; sepals lanceolate, 2½ to 3 lines long, acute, reflexed in fruit; carpels 9 or 10, strongly spreading and widely separated at apex, the summit wing-like.

Specimens examined. Costa Rica: San José, John Donnell Smith, April, 1894 (No. 4751); San José, Tonduz, February, 1893 (No. 7311), and November, 1880 (No. 1452); San José, H. Pittier, December, 1893 (No. 8471); San Rafael, H. Pittier, June, 1890 (No. 2600); San Rafael, Tonduz, February 13, 1890 (No. 1977). Guatemala: Santa Rosa, Heyde & Lux, November, 1893 (No. 6299); Santa Rosa, Heyde & Lux, January, 1893 (No. 4326).

† *Robinsonella Lindeniana* (Turcz.), Rose & Baker; *Sida Lindeniana* (Turcz.), *Bull. Soc. Nat. Mosc.*, 31, pt. 1, 200 (1858); *S. Ghiesbreghtiana*, Turcz. l. c.; *Abutilon* (?) *ambiguum*, (Turcz.), l. c., 205. Shrub; lower leaves large and palmate-lobed, the upper three-lobed above; dark green, somewhat scabrous beneath; pale, densely and softly stellate-pubescent; lobes entire or more or less dentate, four to six inches in diameter on petioles as long or longer; inflorescence ample, cymose-paniculate, its branches and pedicels slender; pedicels six to twelve lines long, jointed a little below the flower; calyx five-lobed; sepals broadly ovate, acute or obtusish, two lines or less long; corolla white; carpels eleven to thirteen, inflated, four to five lines long, somewhat compact. State of Vera Cruz and Valley of Cordova.

as petals. Irises are not much affected by insects, but the nectar of *I. ochroleuca* seems to be very attractive to black ants, some of which will always be found busily engaged on the flowers.

Early June is also the flowering-season of some of our native Irises. The light purple flowers of *I. prismatica* (*Virginica*) appear in our meadows at this time, and the small flowers with grass-like foliage are attractive in the garden. This Iris is a sturdy grower and can hold its own among the thickest grasses. Like our other common but larger "Blue Flag," it grows equally well in wet or dry places. Some ten years ago Mr. W. A. Manda found, near Wilmington, North Carolina, a new "Blue Flag," which had hitherto escaped the notice of the botanists. This is an attractive species, with lax foliage, brown spathe valves and light purple flowers. It has since been found as far north as Bordentown, New Jersey. One of our quaintest and most distinct Irises is *I. fulva*, or *cuprea*, which is a southern species, but perfectly hardy here. This has drooping petals of a terra cotta color quite distinct from any other Iris known.

Among all the tall native Irises, however, we could safely give the palm to *I. hexagona*, the best varieties of which are attractive in form and coloring, bold in size of flower and distinct in habit. It seems to have a wide range, and I have had it from as far west as Idaho and as far south as Florida. It forms thick rhizomes sometimes two feet long, and flowers freely on stems with several heads and several large leaves. These stems are partly prostrate at flowering-time, and the effect is that of a shower bouquet of rich blue flowers with greenish white centres. The best variety which I have seen is that collected in Arkansas by Mrs. La Mance and which bears her name. Besides this, I have varieties with light coloring, and one with an intermediate shade of purple. My friend, Mr. Mead, found in a Florida swamp a pure white variety, but this has not yet been proven to be hardy here, although there seems to be no reason why it should not be. The type is reliably hardy with no protection, and the white variety is evidently only a sport, as seedlings mostly revert to the type. Another winter with plants better established will test the variety more fully.

Elizabeth, N. J.

J. N. Gerard.

### Strawberries under Glass.

AN attempt was made last winter at growing Strawberries under glass in Cornell University, and some details of the experiment are given in a late bulletin prepared by Mr. C. E. Hunn and Professor Bailey. The cloudy climate of Ithaca, where there was not a full day of clear sunshine during the months of December or January, the lack of well-established plants of suitable varieties, and the fact that the only houses available were too high and too dark for the best growth of the crop were serious drawbacks, and yet the success achieved was so considerable that we feel warranted in presenting in a condensed form the main features of the practice adopted:

The plants from which runners were taken were set in rich ground on the 6th of May, but the season was so dry that they made small growth. It is probable that the best results could be expected from the runners of maiden plants set early in the spring or in the autumn before. In these experiments the first lot of plants were grown in two-inch pots plunged under the runners on the 10th of July, the second lot on the 27th of July, and the third on the 22d of August. After growing in the pots for two weeks the plants were shifted into four-inch pots and put in cold frames upon which no glass was placed until very cold weather. They were shifted on into five-inch and finally into six-inch pots and brought into the forcing-houses in succession and carried through to fruiting. The plants remained out-of-doors until nearly midwinter, with no protection except the glass covering, so as to give them a thorough rest by allowing them to freeze perfectly solid. Perhaps this freezing is not essential. Indeed, it is probable that the berries can be raised as well without it, and yet it is believed that a decided check should be given to the plants before they are taken into the houses, and the freezing may help to destroy the red spider and other pests.

Four hundred and fifty pots of the first lot were brought, on the 21st of December, into a house with a temperature of forty to forty-five degrees at night. Dead and diseased leaves were trimmed away, and on the 6th of January the young leaves began to appear freely. The plants were sprayed with ammoniacal carbonate of copper as soon as the first spot of rust appeared, and the house was vaporized at intervals with extract

of tobacco to keep down insects. Many plants were in flower on the 1st of February, and nine days later they were staged near the glass at a temperature of sixty-five degrees at night. The berries were well colored by the 6th of March, and on the 11th the first pickings sold for \$2.00 a quart in Ithaca. The crop continued for about ten days. Most of the plants were of the Beder Wood variety, and although they began to flower when the foliage was very small and scanty there seemed to be enough to carry the plants to maturity. The stamens did not develop strongly in cloudy weather and there was some difficulty in getting enough pollen. The Beder Wood is a perfect-flowered variety, but it only produces enough pollen to fertilize its own flowers. The pollen was transferred every bright day by means of a brush rubbed over the anthers and again over the pistils. The operator always carried a little spoon-like implement made of a watch crystal glued to the end of a small ladle, and whenever any flower contained a superabundance of pollen the dust was shaken into this receptacle for flowers where the pollen was deficient. This process was repeated every clear day, for, as in the case of Tomatoes and other forced plants, the pollen is discharged most freely when the sun is bright and the house is dry. It is essential to pollinate every flower completely, for if one side of the pistils is left unfertilized that side of the berry will fail to develop. After the berries were well set, on the 19th of February, a little manure-water was given, and repeated until the berries were about full-grown. The surface of the pots was at first covered with sphagnum moss to hold the berries from the earth, but two or three days of dull weather brought on indications of rot, and the moss was removed. Some of the pots were then covered with cork-dust, such as is used in packing foreign grapes, which answered the purpose well, but the most successful device was the use of small pieces of wire screen, which kept the berries away from the earth and showed them off to the best advantage.

The second and third lots contained some plants of the Sharpless, Van Deman and a few of Hunn, but the Beder Wood proved the best variety. One of its peculiarities is the small amount of its foliage and the greater prominence of the fruit on this account. The light color of the berries is against it, but it has the advantage of being very early. Hunn is the handsomest berry tested, being large and dark-colored, but it is too late for profitable forcing. The plants of Beder Wood set from eight to twelve berries each, but when small and imperfect ones were removed about six first-class uniform fruits were the average on each plant in the whole lot of four hundred. With stronger plants no doubt eight fruits could be averaged. Because the pots are set so close together it is possible to secure a larger yield to the square foot under glass than is obtained in the field—that is, a quart can be grown on from two to three square feet of floor-space, and allowing for walks and other waste the yield would figure up to four hundred bushels to the acre.

The bulletin gives the following summary of points which should be especially noticed in the cultivation of Strawberries under glass: (1) Very strong plants to begin with, which have been kept in vigorous growth and not allowed to become pot-bound until they have reached six-inch pots. (2) Varieties which are early, or, at least, not later than midseason, and preferably those which themselves produce an abundance of pollen. (3) The exercise of great care to have the plants free of fungous diseases and insects before they are put upon the benches. (4) The devoting of an entire house to the crop. If two or three different crops are grown in the same house none of them can receive the very best treatment which they demand; and if there are other plants in the house which are infested with red spider, the pests will spread to the Strawberries, and it is very difficult to dislodge them without keeping the plants so wet that pollination is interfered with and rot threatened. (5) Growing the plants as close to the glass as possible. (6) In the dull months constant and careful attention to hand pollination. (7) Liberal applications of liquid-manure two or three times a week after the fruits have begun to swell. (8) Exercise of care that the berries do not lie directly upon the soil or upon a wet surface.

**Asparagus Sprengeri.**—This plant has not only all the merits noted by Mr. Orpet, but is also a very decorative and useful house plant either in a suspended basket or placed on a standard or pillar, which its profuse sprays of foliage will soon cover. It is a clean plant with a distinct effect, and only requires, like most plants devoted to domestic use, a certain acclimation; after which it endures well the modern house conditions of light and heat and requires no special skilled

attention. Mr. A. Blanc is entitled, I believe, to the credit of introducing this plant in the United States.

### Fir-tree Oil as an Insecticide.

To the Editor of GARDEN AND FOREST:

Sir,—The following notes upon the use of Fir-tree oil against certain insects not readily amenable to insecticides, may interest some of your readers. For the past two years hardy Roses in this neighborhood have suffered severely from the attacks of at least three insects: first, a species of aphid, or plant-louse, which swarms upon the tender new growth and upon the flower-buds; secondly, the larvæ of one or more species of moths belonging to the genus *Cacœcia*, which damage the foliage and flower-buds; and lastly the leaf-hopper, a small, white, winged insect which lives upon the under surface of the leaves, sucks the juices, and thereby causes irregular white spots upon the upper surface of the leaves.

The damp weather and frequent rains of May induced a rapid growth of succulent tissue, and early in the month the aphides appeared upon Roses in enormous numbers. Attempts were made to eradicate the pest by crushing, but the survival of two or three individuals was sufficient to infest the plants completely in a day or two. About the middle of May the worms began to appear, one kind, of the "inch-worm" type, from half to three-quarters of an inch in length, and attacking the leaves principally; the other a trifle larger, grass-green, with a black head, and usually found neatly ensconced in a rolled-up leaf, whence it emerges and attacks the flower-buds, gnawing out the inside completely. Upon being disturbed, this larva becomes extremely active, writhing about on the palm of the hand or wriggling quickly from the leaf and dropping to the ground. Last year I dusted the Roses thoroughly with hellebore, naturally with no effect upon the aphides, but, to my surprise, with very little effect upon the worms. This year I have tried spraying the plants with two insecticides, both separate and combined, with entirely satisfactory results—at least in the case of one of them. Upon a large Queen of the Prairie Rose I used a decoction of tobacco made by steeping one pound of tobacco waste in two gallons of hot water. This was used while still warm, and was applied by means of a small force-pump attached to a pail and provided with a Vermorel nozzle. Upon this plant the aphides alone were present, but in very great numbers. The first treatment resulted in the death of about fifty per cent. of the insects, and it was repeated a week later. These two treatments, however, have not proved sufficient or wholly satisfactory.

To two gallons of the tobacco decoction, made as described above, I then added a quarter of a pint of Fir-tree oil, and with this I sprayed six large plants of Polyantha Roses. These plants were covered with buds, had produced an abundance of tender shoots, and were badly infested with aphid and with the green larvæ mentioned above. A careful examination of the plants on the day following the treatment showed that fully ninety per cent. of the aphides had succumbed, while upon the six plants only two or three living larvæ were found, the liquid having penetrated the folded leaves and killed the larvæ within the fold. A spray consisting of a quarter of a pint of Fir-tree oil in two gallons of clear water produced a like beneficial effect upon six other Polyantha Roses, and in neither case did the application result in any damage to the most tender tissues. This experience confirmed what I had previously known regarding the value of Fir-tree oil as an insecticide. A spray or wash made of half a pint of the oil in two gallons of water completely destroys the scale insect so detrimental to Orange-trees grown in the house or under glass. A single treatment causes the scales to become brown and dry, so that, if desired, they may be gently wiped from the plant. Against woolly aphid upon plants in the greenhouse, Fir-tree oil has proved invaluable. This substance is expensive (seventy-five cents a pint at retail), but a little goes a long way, and the odor, by no means unpleasant even in the house, is soon dissipated.

I am aware that a suds made of whale-oil soap, or even of common soap, has often been pronounced "as good as anything" against aphides, but for general utility, thorough effectiveness, ease of application and cleanliness, I know of nothing which equals Fir-tree oil. It is to be hoped that an increased demand will lower the price of this substance, so that its value may become more generally appreciated.

New Haven, Ct.

W. C. Sturgis.

### Pokeweed as a Vegetable.

To the Editor of GARDEN AND FOREST:

Sir,—Mr. Chamberlin's list of wild plants which are used as "greens" in the various parts of the country (see page 239) might be considerably extended. It seems rather remarkable, however, to a resident of this city that Pokeweed, *Phytolacca decandra*, should have been omitted, especially since Milkweed is mentioned as a substitute for Asparagus. The young shoots of the Pokeweed are not at all uncommon in our markets and on our sidewalk stands, and when cooked like Asparagus they are very tender and have a flavor that is highly relished by many people who flatter themselves that their palates are not uneducated.

## Exhibitions.

### Flower Show in New York City Hall.

THE New York Gardeners' Society, by permission of the Mayor and Aldermen of the city, held a flower show on Saturday last in the Aldermen's Chamber of the City Hall. The society consists mainly of private gardeners, and they certainly brought together one of the most interesting and varied exhibitions of flowers ever seen in this city. The Roses, of course, were in great abundance at this season, and standard varieties of all classes were shown in first-rate form. Among the newer ones were Bardon Job in the collection of Hicks Arnold, a large semi-double cup-shaped flower of a singularly rich crimson color, and Mr. W. A. Manda's hybrids between *Rosa Wichuraiana*, and certain Tea Roses like *Perle des Jardins* and *Madame Hoste*. These flowers have the true Tea fragrance and the plants have evergreen leaves. Mr. Manda also showed hybrids between *Rosa Wichuraiana* and the Hybrid Perpetuals. There were fine cut flowers of *Odontoglossums* and *Cattleyas*, and a magnificent plant of *Cattleya guttata*. The Japanese *Hemerocallis aurantiaca* was shown in first-rate form, and its rich color and large size make it a welcome addition to this beautiful genus. A new snow-white *Carnation* of fine form and fragrance, and on long stout stems and called *Greater New York*, was much admired. In the collection of Mr. John Lewis Childs a vase of the spikes of *Lilium tenuifolium* and another of the rare *L. Parryi* were exhibited, but to specify all the good flowers seen would be to give a catalogue of everything in bloom at this season. A few belated German Irises and a few early Japanese Irises were mingled with a great abundance of Spanish Irises now at their best, *Gaillardias*, named *Pyrethrums*, a *Coreopsis*, which by crossing or selection is distinct enough to deserve the name of *Harvest Moon*, *Delphiniums* of every shade of blue, masses of *Heuchera sanguinea*, upright *Clematises*, *Thermopsis Caroliniana*, beautiful strains of *Aquilegia*, *Centranthus*, the best new Sweet Peas, *Scabiosa Caucasica*, new *Pæonies*, single and double, with *Canterbury Bells*, *Sweet Williams*, *Foxgloves*, *Centaureas* and many other old-fashioned flowers. Besides these there was a good collection of fruit and vegetables. The exhibition was a credit to the gardeners of this vicinity on account of its quality, and they deserve the thanks which the Mayor gave them in a graceful speech, not only for making a free display at this busy season, but because they gave all the flowers to poor children, the inmates of city hospitals and others who have few opportunities to enjoy beauty of this sort.

The principal prizes were taken by G. Reilly, gardener of William Brown; A. Herrington, gardener of H. McK. Twombly; Richard Sherry, gardener of George W. Bramhall; F. Mongold, gardener of Miss Helen Gould; A. Taaffe, gardener of Miss Mathieson; A. Grierson, gardener of Hicks Arnold; William Anderson, gardener of J. M. Constable; A. J. Wengerten, gardener of Cornelius N. Bliss; William Scott, gardener of Mrs. T. Eastman; A. L. Marshall, gardener of J. B. Dutcher; A. L. Brill, gardener of Miss Monahan; Robert Marks, gardener of Mrs. De La Vergne; W. Bartholome, gardener of W. B. Isham; O. E. Owens, gardener of M. Crawford; James Kirby, gardener of Mrs. S. D. Ripley; John G. Aitkins, gardener of M. R. Cook; W. H. Harvey, gardener of Obert Parks; Job Ash, gardener of Miss E. J. Clark; F. R. Poirkovsky, gardener of Mrs. Reynal.

## Notes.

The destruction of the forests which has been going on about the diamond mines near Kimberley, South Africa, is believed by Dr. William Crookes to have seriously modified the climate. The country within a radius of a hundred miles has been stripped of wood to supply timber for the mines.

The forests were barriers against the wind; they tempered the heat of the sun in a region where the air is extremely dry, and their removal is thought to account for the dust storms which have been so frequent in that country this year.

Professor N. E. Hansen, Horticulturist of the United States Experiment Station of South Dakota, at Brookings, was recently appointed a special agent by the Secretary of Agriculture to visit eastern Russia, Siberia, and the elevated plateaus of central Asia, to gather garden, farm, fruit, shrub and tree seeds. Professor Hansen states that the few plants from this dry inland European region already tested in South Dakota, Manitoba and the north-west territory have proved hardy, and it is his intention to collect during the present summer and autumn as complete a representation of the plants of that region as possible.

In some places anthracnose of the Black Raspberry has been so prevalent and virulent as to warrant the special study which has been made at the Geneva Experiment Station in this state, and a late bulletin suggests the following measures of prevention and cure: Use only healthy plants and adopt a short rotation of crops. Protect the new shoots in spring by spraying with Bordeaux mixture when they are about six inches high, or spray for the first time when the first few spots appear on the young canes. This should be followed by two or more other sprayings at intervals of ten or fourteen days. Old canes and badly diseased new ones should be removed as soon as the fruiting season is over.

The sixty-sixth fair of the American Institute of this city will be held in Madison Square Garden, September 20th to November 4th. The exhibition of the agricultural and horticultural department will continue from September 27th to October 23d, in the Concert Hall, and will comprise plants, flowers, fruits, vegetables and cereals. No entrance fee is required for exhibits in this department, and there are classes open to amateur and to commercial growers. An interesting feature will be the display of vegetables grown on vacant-lot farms. Those who intend to exhibit in any of the classes of this department are requested to notify Dr. F. M. Hexamer, No. 52 Lafayette Place, New York.

The first new apples, green and small, came from North Carolina last week. Niagara grapes, from Florida, are already offered here, a three-pound basket of large-berried attractive bunches costing forty-five cents. Other new-crop fruits are currants and black and red raspberries from Maryland, Delaware and New Jersey. Watermelons and muskmelons are now of good size and flavor and sell readily. Choice English gooseberries of immense size bring twenty cents a quart. Nectarines, from California, large and showy, cost fifty cents a dozen, and new grape-fruit, from Jamaica, twenty-five cents apiece. Forty-four car-loads of California fruits were sold here last week. Lemons have advanced \$1.00 a box during the past ten days, in anticipation of warmer weather.

At the Annandale Rose Show, held last week under the auspices of the Dutchess County Horticultural Society, one of the leading features was a collection of Orchids, Crotons and greenhouse plants from the Dinsmore estate (Mr. Thomas Emerson, gardener), and Gloxinias from Archibald Rogers, Esq. (Mr. James Horrocks, gardener). The principal prize-winners were Wallace Gomersall, gardener to Winthrop Sargent, Esq., who took the silver cup for the best twenty-four distinct varieties of Roses; Mr. Richard Lewis, gardener to Miss Cruger, who won the society's prize for the best collection of outdoor Roses, and Thomas Harrison, gardener to Ex-Governor Morton, for Roses in various classes. Miss Cruger's exhibit of vegetables and Ex-Governor Morton's strawberries were exceptionally good.

The early blight of Celery is sometimes very destructive in the hot midsummer weather, and when the young plants are set out it is advisable to dip the leaves in some fungicide, the ammoniacal copper carbonate solution being most promising so far as known. The formula generally used is eight ounces of copper carbonate and three pounds of ammonia water (26°) added to forty-five gallons of water. In fields where the disease has prevailed in previous years many of the spores have undoubtedly been carried over during the winter, and it is best not to wait until the spots appear. If the plants should be sprayed at intervals of two weeks with the same solution, or one a trifle weaker, the disease may probably be prevented. Dry sulphur has been used with considerable success at the experiment station in New Hampshire, dusted on the plants at the rate of one pound to six hundred plants. It

should be remembered that this disease, *Cercospora Apii*, is quite distinct from the late blight which begins before the other fungus has completed its work and continues its activity even after the crop has been stored.

Among the latest teachers' leaflets which are intended to help on "nature study" in the common schools of the state of New York, and prepared by the College of Agriculture of Cornell University, are two relating to insects, by Anna Bottsford Comstock. One of these is entitled "Some Tent-makers," and it contains suggestions for lessons in the life of the Apple-tree tent caterpillar, commencing with its eggs, and then explaining how to watch the caterpillars as they shed their skins, make their cocoons, etc. Another leaflet gives hints about making collections of insects. The directions are very practical, and in the hands of a skillful teacher they can undoubtedly be made of great use in training the mind and eye of pupils while young and receptive to habits which will be of inestimable value to them later in life.

Many volumes of conjecture have been written about the influence of woodlands upon climate, and especially upon the influence of forest areas on the humidity of the air, but authentic data are still needed. We are glad, therefore, that a series of observations upon this point has been instituted by Professor Corbett, of the South Dakota Agricultural College. A set of hygrometric and other instruments was placed in an open cultivated prairie some four hundred feet from the edge of a grove fifteen acres in extent, and another one was placed within the grove. Practically these fifteen acres are only a grove in embryo, since the Box Elder, Cherry, Maple and Scotch Pine trees of which it consists have only been planted six years. Without going into details of temperature at the surface and below the surface of the soil we can only say that the average daily humidity reported in the open prairie during six months, as ranging from sixty-two to seventy-four per cent., was less than the daily mean humidity in the so-called forest by from two per cent. to ten per cent. This would seem to indicate that the influence of trees is felt in some ways long before they are fully grown.

String-beans, estimated by the number of packages, seem to be among the most popular vegetables, for, besides 25,471 boxes of unclassified vegetables sold in the New York markets, and which included some beans, nearly 25,000 packages of green and wax beans were received here last week from states between New Jersey and North Carolina. Other vegetables handled in large quantity were cabbage, of which more than 16,000 packages reached our markets last week, and there were even more cucumbers. Tomatoes, firm and of good quality, are now coming from Florida, Mississippi and Georgia; large new onions, from Louisiana, Maryland, Virginia and Delaware; besides cabbage from the south, considerable quantities are brought from New Jersey and Long Island, as are peas and asparagus. Eggplants, Yellow Marrow, Crookneck and scalloped squashes, turnips, cauliflower, kohlrabi, beets, radishes, carrots, okra, peppers, garlic, celery, rhubarb, mushrooms, Romaine and other lettuces are all seen, well-grown and fresh-looking, from near-by and remote states. Almost 60,000 barrels of new southern potatoes were consigned to this city last week, many from as far north as Virginia, and old potatoes are still plentiful.

At the meeting of the American Institute Farmers' Club on June 8th, Mr. T. J. Dwyer, in the course of an interesting address on Strawberries, said that he considered Marshall, Brandywine and Parker Earle the three leading varieties of the time, not for any specially favored locality, but for cultivation over a wide range of country. The plants of Marshall are luxuriant and healthy, with dark, rich foliage, perfect flowers and large handsome, uniform fruit of the highest flavor, of dark rich color and no white point. It is a firm shipping berry, ripening early and continuing in good form until late, its season covering almost an entire month. Brandywine is also a strong grower with fine foliage. It is very productive; the fruit averages nearly as large as that of Sharpless and retains its size from midseason until late. The flavor is not the very best, although it is fair, and the fruit is firm and of good shape. The fruit of Parker Earle is firm, light red, with a short neck and about the same size as the old Charles Downing. The plants have a tendency to make very large stools, so that a single plant not infrequently yields two and three hundred blossoms and berries. Of course, so prolific a variety needs a great amount of food, and when abundant water and fertilizing material are provided this is a highly profitable berry for market.

Natural Beauty in Urban Parks.

WHETHER our appreciation of the beauty of natural scenery becomes profounder and more sympathetic with what we fondly term the advance of civilization is a subject which it is not our purpose here to discuss, although volumes have been written on the question. What we do know beyond dispute is that men and women of refined taste always feel something like indignation when they see natural beauty needlessly defaced. It is this sentiment which moved the Prime Minister of England a few years ago to advocate an act of Parliament to protect the scenery of Great Britain from vulgarization by the paint-pot of the advertiser, which impelled the Massachusetts Legislature to pass a law making it unlawful to proclaim in staring characters the virtues of a patent medicine, and which has clothed the Park Board of this city with authority over signs erected within three hundred feet of the public grounds in this city. The same feeling impelled Mr. Charles Eliot, seven or eight years ago, and his co-workers not only to make an organized effort to protect beautiful scenery from disfigurement, but to secure it as a possession of the people forever. To serve this end the Board of Trustees of Public Reservations was founded, which has been the model for many other organizations of this sort. No one can doubt, too, that the great majority of the enlightened people of Greater New York feel that somehow their personal rights are invaded by the disfigurement of the Palisades which is now going on, and there can be no question that the Legislature of this state never passed an act more thoroughly in accord with the sentiment of the whole people than the one which set apart Niagara Falls as a reservation to be the property of all the people. The National Government has recognized the same sentiment in not permitting Yosemite Valley and the Yellowstone region to pass into the hands of individuals as private property, but has taken these two great national wonders, as well as certain Sequoia groves, and held them permanently for public enjoyment.

In regard to places so noteworthy for sublimity or features of unique beauty there seems to be a feeling that these, at least, are the common heritage of all the people, and it runs counter to our innate sense of right that

great mountain peaks or natural objects of commanding grandeur should be the private property of an individual to be monopolized for personal profit or subject to the passing whims of any puny mortal. But if we adopt this reasoning we may as well go a step further and hold that all natural beauty is the inheritance of all the people, that it has a distinct value to them just as clear air and pure water have, and that the men who needlessly scar the face of nature or turn it into a desert when they bore their oil wells, dig out ore, quarry rocks, or build factories and railroads, are as truly public enemies as those who pollute springs of running water or load the air with noxious vapors. It is certain, at all events, that men who appreciate their duties as citizens will not needlessly mar the beauty of the earth in which we live, they will not wantonly destroy the forests which give a glory to our landscapes, and they will treat with reverence natural scenery whose grandeur has an elevating influence and whose beauty brings refreshment to the spirit.

We are safe, too, in asserting that beautiful natural scenery has a positive value as a refreshment to the mind, especially of those who are worn and wearied by the stress of city life. This is not a mere metaphor. It is asserted over and over again, not only by poets and philosophers who give expression to the profoundest truths in our nature, but the curative value of natural scenery is distinctly recognized by the medical profession. All of us have felt the soothing and restful influence of natural beauty, acting in a subtle way through the very highest functions of our being, and tending to establish sound minds in sound bodies. When a city possesses a piece of scenery like Mount Royal, for example, it owns something more than so many acres of land whose beauty has power to attract the residents of the city to visit it for the sake of fresh air or exercise, or for a change of mental occupation. Such scenery, as is delightfully shown in a pamphlet published by Mr. Frederick Law Olmsted nearly a score of years ago, acts "in a directly remedial way to enable men to better resist the harmful influences of ordinary town life and recover what they lose from them. It is thus, in medical phrase, a prophylactic and therapeutic agent of vital value. There is not one in the apothecaries' shops as important to the health and strength and to the earning and taxpaying capacities of a large city." Whenever, therefore, a city possesses park-lands with exceptionally beautiful features, their preservation, even from a pecuniary standpoint, means the saving of capital; it is the husbanding of a source of health which is the source of all wage-earning power and the foundation of all wealth. The preservation and enhancement of natural beauty in public parks ought, therefore, to be insisted on, not from sentimental considerations alone, but for reasons based on the most substantial and practical truth.

When we consider the almost universal admiration and even affection among civilized men and women for broad natural landscapes, for "scenery as distinct from scenes," and consider its special restoring effect upon those who suffer from the nervous strain of city life, we have the one justifying reason for large urban parks. Small parks and playgrounds, formal squares, plazas and promenades are all valuable for other purposes, but for the highest rest and refreshment nothing will fill the place of stretches of beautiful natural scenery. Artificiality, the needless intrusion of buildings, anything which interferes with seclusion and the actual contact and communion with pure nature, defeats to some extent the highest purpose of such parks. The idea should never be harbored that rural parks can be improved by buildings however noble, by any work of art which is not entirely in harmony with the spirit of the scene, or by so-called decorative gardening, however choice and rare the plants employed. It is with regret, therefore, that we hear of a threat to erect a large museum in one of the Buffalo parks. No matter how stately the building will be, no matter how attractive or instructive the material it contains, it must forever be a defacement to the

scenery, which is the essence of the value of the park. No city in the world possesses more beautiful scenery or a park area more thoroughly characteristic of what is most delightful in the landscape of the part of the world in which it is situated than does New York in Bronx Park. There seems to be some danger that a portion of it which has been handed over to the directors of the Botanical Garden may be marred by the intrusion of buildings which could be placed elsewhere. Let us hope that conservative counsel will prevent any such desecration. The city spent money like water to create some charming natural scenery in what is now Central Park by blasting out ridges of rock, filling in the spaces with soil, and turning this desert of stone into tree-flecked meadow-land. Now that it has come into possession of scenery far more beautiful and ready-made, it would be worse than folly to destroy it.

### Private Forestry and State Forestry.—III.

TOWNSHIPS\* and counties, generally speaking, are scarcely qualified to own such reservations. Nearly all of these are so poor or so unstable as to render forest management impossible, except such as is merely meant for revenue. The population of the counties is too shifting to be interested in far-reaching local undertakings. Besides, if all the surrounding counties do not unite in the scheme, steps toward solving the forest question by a single community are useless. Forests are most needed in counties situated in mountainous regions, at the headwaters of the streams. But these are the very counties that, suffering comparatively little from the consequences of forest destruction, do not care to spend any money in the matter. The lowland counties are the interested ones, but they cannot legislate for the territory of other counties. The state alone, as the aggregate of all the counties, is capable of establishing and managing reservations. A public loan to buy such areas as must necessarily be kept under forest-cover—whether wood-clad now or not—might be obtained at a low rate of interest, as the security, consisting of real estate, renders it a safe investment. The United States, if necessary, might guarantee such loans, thus still further reducing the interest to be paid.†

There is most need of purchase by the state of such tracts as cover the steepest and highest ridges. These tracts command the lowest price, being but thinly stocked and more exposed to fire than to the lumberman's axe. Large areas, usually of bare land, are annually sold for taxes.‡ The state should secure those that are suited for a reservation and reopen them to the production of timber, which, in most cases, is the only possible product. Reforestation cannot, of course, be accomplished at once. It can be done gradually, the most urgent cases first. When protected from fire, some part of such reservation will be restocked in the course of time by nature. If any human action, apart from fire protection, is needed on such part, it will only be the closing of ravines and gullies. Any delay will greatly increase the cost, the land becoming more impoverished, natural regeneration more doubtful and the gullies growing worse. The less feasible it is to enforce maintenance of a forest-cover on lands owned by private persons the more urgent is the duty of the state to secure such tracts for itself.

A singular solution of the forest question is at the present moment recommended by the Minnesota State Forestry Association to the legislature of that state. The plan, drafted by Captain Judson W. Cross, provides "that persons may deed to the state for forestry purposes such land as is

unfit for agriculture, reserving the right of hunting for themselves, and the right to dig, mine and carry away such minerals, oils and coals as may be found on such land." No taxes are to be paid on it. The expected revenue from forest crops is to be divided as follows: Two-thirds shall be paid to an educational institution, and the remaining third to state, county and township, to reimburse them for loss of taxes. The Minnesota forestry plan, if it becomes a law, will provide an inexpensive method by which the state may secure large bodies of lands, which is the first and most important step toward state forestry. The next step is protection from fire, after which forest management might follow.

I might here describe the means by which the German Government has induced wealthy individuals to buy utterly worthless land and plant it with trees after having restored it to productiveness by steam-plowing and drainage. Such plantations are free from taxes for forty or fifty years.\* The Government forest guards protect them from fire in connection with the work of protecting Government lands; the plants are furnished from excellent Government nurseries at cost price. The usefulness of this latter arrangement I cannot state strongly enough, and similar methods should be at least tried in this country.† The idea is not at all contrary to American principles; why can we not distribute plants from Government nurseries as fish are distributed from Government hatcheries? The prices which commercial nurseries quote are simply exorbitant, and the dealers are not prepared to furnish the kinds required in sufficient quantities at any price. Plants produced in forest nurseries en masse can be raised at one-tenth the expense.

Private enterprises, although fostered by the state, will, however, never solve the forest question. State forest reservations are a necessity wherever forests act as "barriers against losses." The reservations must be protected from marauders and fires by a staff of forest guards, with the necessary number of officers. The forest guards, wherever feasible, should also be employed in enforcing fish and game and forest-fire laws on private lands which may surround the reservations. An administration of this kind is as economical as it is effective. Strict discipline and freedom from political influence are necessary, and therefore a connection with the army seems advisable.‡

Biltmore, N. C.

C. A. Schenck.

### Dock Gardens.

PIER parks or promenades were suggested by Mr. W. D. H. Washington in a report to the Tenement-house Commission of 1894. The idea so evidently contains the germ of practical relief for a crowded population in hot weather that under the charter for Greater New York the Dock Board is expressly authorized to plan certain piers in such a way that they will serve for purposes of recreation.

Mr. Olmsted once said, in support of a proposal to make a waterside park, that in such parks "for one acre of land you procured a thousand acres of space and fresh air." Mr. Washington states that a dozen of such pier parks as this could probably be created for little more than the cost of a park covering a single block in the city. His description will do equally well for the present plan, on page 253, which claims no other merit than an attempt to design an attractive formal garden and playground on architectural lines for the space at command. The structure, 544 feet

\* In the United States exemption from or reduction of taxes on areas planted up is granted in Massachusetts, Wisconsin, Dakota, Montana and Utah. Iowa has repealed a similar law in spite of its apparent success. Indiana is going to grant a small reduction.

† The United States Division of Forestry was created for "the collection and distribution of valuable economic tree seeds and plants," among other objects. For lack of funds, however, practically nothing has been done as yet. (Report of United States Division of Forestry, 1890, p. 197, and 1891, p. 193.) The direct aid which the United States Government has held out in the interest of forest culture has consisted in permitting the acquisition of Government lands in the treeless region free of expense, by planting one-sixteenth of the area to trees. This method has proved of little avail. (Report of United States Division of Forestry, 1890, p. 197.)

‡ Professor Charles S. Sargent's excellent plan (*Century Magazine*, February, 1895, page 626). The majority of the forest guards in Germany are taken from the army.

\* In Maine 1,000 acres of land are set aside in each township for public purposes, probably a good deal being timbered. But no enactment in reference to these lands exists. (Report of United States Division of Forestry, 1887, page 98.)

† Such a loan could and should be made the favorite investment of the thrifty workman, enabling him to invest money as safely as in a Government savings bank. The poor laborer all over the world is likely to lose his savings through investing them in speculations, the financial standing of which he has neither the education, the experience nor the means to investigate.

‡ In Pennsylvania the land advertised to be sold for taxes in June, 1894, amounted to more than one and a half million acres. (Governor D. H. Hastings' Message.)

long, 75 feet wide and 25 feet high, is to be built of steel and iron on the existing dock and foundation. The dock is flat, constructed on fire-proof arches and finished on top with a layer of Portland cement concrete, over which is a coat of asphalt, graded to carry off the water into gutters and thence into the river. Such a structure would be practically fire-proof. This dock would be reached by staircases at the land end under a portico.

The grass-plots and flower-beds would be surrounded by a curb to receive the soil in which the plants would grow. This gardening would need care to secure a maximum of effect with a minimum of expense, but need not be costly, though it would require annual renewal. Arbored walks could easily be covered with quick-growing flowering creepers and the beds filled with the common and ever-popular flowering plants. The portico and shelters roofed with iron could be provided with awnings like those on the open street-cars for shade and to turn a shower of rain. These shelters surround a playground for children, with a sand-heap in each corner. At the far end is a band-stand surrounded by arbor-shaded seats. Two drinking-fountains and plenty of benches complete the outfit, which should be surrounded by a high light fence for the prevention of accidents.

New York. *W. Hamilton Bell.*

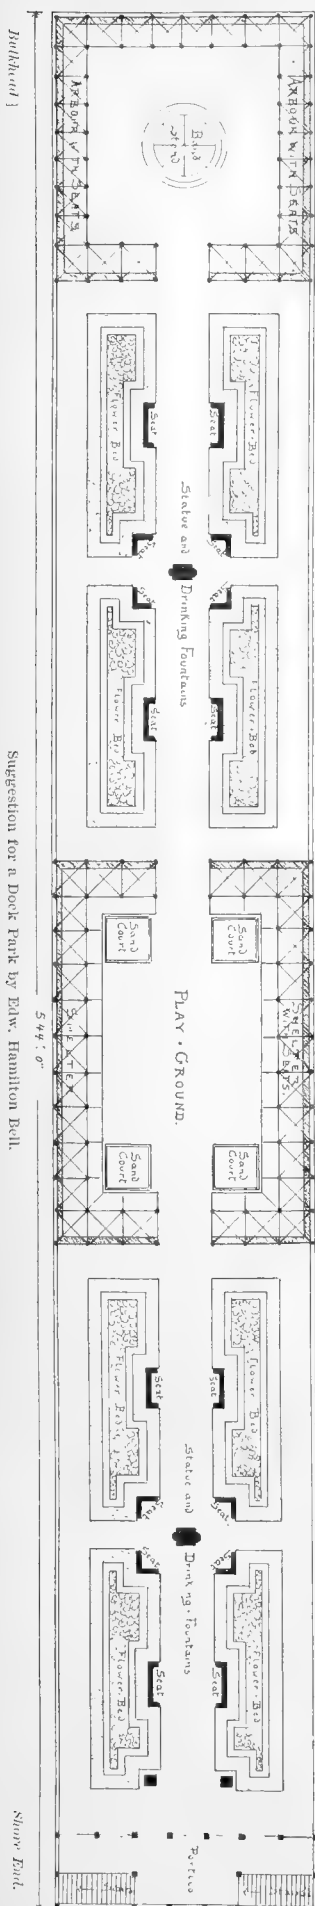

#### Roots in Commerce.—I.

ONE scarcely realizes how largely products of vegetation enter into use in the arts and the household in construction, for utensils, food, and a thousand other purposes. If, for example, we take up a wholesale drug circular, in the part set aside for "drugs and dyes" one will find several columns which include price lists of woods, barks, flowers, leaves and roots. To give some idea of the variety of these materials, the distant parts of the world from which many of them come, and the purposes for which they are made to minister to the wants of man, it is only necessary to glance at a single section, as, for instance, the roots. A trade list of roots names such familiar native plants as Blackberry, *Rubus villosus*, and *R. Canadensis* (the Dewberry),

the roots of which have tonic and strongly astringent qualities. Bloodroot, the root of *Sanguinaria Canadensis*, is also a regular article in trade. This plant, prized for its beautiful snowy flowers in early spring, is called also Puccoon, Tetterwort, Tumeric and Indian Paint, the latter name, doubtless, gained from the red juice of the bright-colored root. In trade its value is in its acrid, emetic properties and its use as a stimulant expectorant. The common Burdock, with its adhesive burs, a plant used largely as a food in Japan, as was described in an interesting article on page 143 in this volume, is one of the most popular of all the medicinal roots, both as a home remedy of country folks in spring-time, and in pharmacy, and is an ingredient in many of the patent medicines sold as blood purifiers. So greatly has the demand increased in recent years that, besides the large quantities grown in America, probably one hundred tons a year are imported from Europe. It is specially cultivated abroad, and imported roots are of better quality than our home product and cheaper, seven cents a pound being an average wholesale price. Calamus, the spicy delicacy of country school children, is another standard article of commerce, and comes whole and sliced, some of it known as white calamus, being bleached. The root of Calamus, or Sweet Flag, *Acorus Calamus*, has a pungent, aromatic taste and is credited with stomachic properties. It is also used as an adjuvant to tonic or purgative medicines. About four-fifths of the quantity consumed in this country comes from Germany. The entire root sells for six and a half cents a pound in wholesale lots, while that which is bleached and sliced brings three to five times as much.

Of Dandelion-root about one hundred tons are used in this country each year, half of it home-grown and the remainder from the fields of Germany. Its commercial value consists in its use in hepatic derangements and digestive troubles generally. Roasted and powdered, it is sometimes bought for coffee by the unsuspecting housekeeper. A native of the southern United States, esteemed for use as an anti-periodic in malarial fevers, is the root of *Gelsemium*, the yellow or false Jasmine, *G. sempervirens*. Perhaps a dozen sorts of Snakeroot are regularly listed, this name being given to many plants whose form or color is suggestive of a serpent. That known as Virginia Snakeroot is *Aristolochia Serpentaria*; the Black Snakeroot of trade may be *Sanicula Marilandica*, or *Cimicifuga racemosa*, while Seneca snakeroot may be some *Liatris* or *Eryngium*; white snakeroot is *Eupatorium ageratoides*. The general name is also applied to other roots, all of which have some reputation as remedies for the bites of serpents, and they are used as stimulants.

One of the most widely distributed American plants, which is nevertheless the most costly of all the medicinal roots, notwithstanding that the medical profession here hardly recognize it and regard it as inert, is Ginseng, *Aralia quinquefolia*. The entire product is eagerly collected and sent to China, where the demand is constantly increasing. This root has somehow caught the fancy and faith of the Celestials and is highly prized as a cure-all, and especially for supposed rejuvenating qualities. When the supply for China depended entirely upon that grown at home the roots had fabulous value, with their supposed power to prolong life. Phenomenal prices are paid for roots, which, in Chinese imagination, resemble dragons or other mythical objects, and a specially grotesque specimen with an imaginary uplifted head, many legs and an angry-looking tail, in the hands of a New York exporter of the root is stated to be worth its weight in gold. Collectors find it as near-by as Westchester County, and, indeed, the largest and highest-priced roots come from New York, West Virginia and Pennsylvania. The southern gatherings are of smaller roots, but even these, mainly from Tennessee and Kentucky, command \$2.70 a pound in wholesale lots here in New York, and larger ones of eccentric form from the northern states sell for \$6.00 a pound. Another native root-stock used in pharmaceutical preparations is that of the herb

Golden Seal, *Hydrastis Canadensis*. Not only has the home demand greatly increased in recent years, but large quantities are exported, as the efforts to cultivate it abroad have not been successful. It grows in the rich moist soil of the woods of our north and north-western states, and the extract has a phenomenally wide range of uses. A century ago it was generally used by the Indians for making a yellow dye. Mandrake-root, the laxative remedy of many households, known under its botanical name of *Podophyllum*, the May-apple of our woodlands, is another article of export. Of course, this must not be confounded with the Mandrake of the Mediterranean region, which belongs to the Nightshade family, and whose fleshy, forked, narcotic roots are often supposed to resemble a man in form.

Pokeroot, as it is called in commerce, *Phytolacca decandra*, is credited with a variety of helpful and wholesome qualities; the berries are said to be useful to reduce obesity, while the roots are hopefully used for rheumatism and as a poultice to induce suppuration. The green roots are five or six inches in length, an inch in diameter, and divided into several branches; when dried they are a light yellowish brown in color and much wrinkled. They are odorless, with a somewhat sweet taste followed by a sense of acidity, and are said to be emetic, purgative and somewhat narcotic.

Among imported roots are Aconite, native to the mountain forests of France, Switzerland and Germany, and cultivated in the latter country and in Great Britain. It has been introduced into America as an ornamental flowering plant, and the roots cultivated in the United States are found to be richer in the active alkaline principle than those imported. The ancients understood its poisonous principles, but it was not until less than one hundred and fifty years ago that it was used in medicine, and considered beneficial for the circulation and the nervous system. Another poisonous European root is Belladonna, the Deadly Nightshade, which grows wild and is cultivated in Great Britain and Germany. The corms of *Colchicum*, Meadow Saffron, from France and southern Europe, are used as a principal ingredient in all the famous old English gout remedies. Of Gentian-root, which comes from France whole and powdered, about three thousand tons are used here annually as the basis of tonic medicines. It has the recommendation of cheapness, costing from six to seven cents a pound wholesale. Most largely used of all, and imported in hundred-ton lots from Asia Minor, Southern Russia, Greece and other south European countries, is Licorice, the slender sweet root of the leguminous plants *Glycyrrhiza glabra* and *G. echinata*. Besides the dried roots, much of the extract is imported in rolls packed in Laurel-leaves, that from Italy being of the highest quality, and similar rolls are manufactured in this country. In pharmacy it is used as a demulcent in cough mixtures, to modify the taste of unpleasant medicines and to give consistence to pills and troches. Large quantities are sold for flavoring confectionery, tobacco and beer, and since the time of Elizabeth it has been cultivated in England to supply the demand of porter brewers. The Orris-root of trade is the rhizome of certain species of *Iris*. That known as Florentine, from Italy, is the highest grade, north Africa furnishing a somewhat lower quality, while a cheaper kind comes from the East Indies. It was once esteemed as a stimulant, but now is used only in perfumery and to scent powders and oils. Its fragrance, which suggests violets, is acquired in drying. Squill, from which the popular croup syrup is manufactured, and known also as Sea Onion, is the large bulbous root of *Urginea* (*Scilla*) *maritima*, which sometimes weighs fifteen pounds. The root contains 22 per cent. of sugar, and is used in the manufacture of whisky in Sicily. The supply is drawn from the countries and islands of the Mediterranean. Ipecac, the root of *Cephaelis Ipecacuanha*, reaches us from Brazil, by way of London, since the output is controlled by English capitalists, who keep the price to our importing

merchants at an average of \$1.50 a pound. Kava Kava, the large spongy root of *Piper methysticum*, comes from the Sandwich Islands. Used immoderately it has a peculiar intoxicating effect with great loss of muscular power, but is valued in medicine as a stimulant. The rhizomes and roots of Lily-of-the-valley were once popular in Russia as a remedy for dropsy. The root-stock of this plant is imported in pieces two or three inches long, covered with fine rootlets, and has a bitter taste. It has purgative qualities and is said to be sternutatory. Elecampane, introduced from Europe and familiar in our gardens and naturalized in the meadows and along the roadsides of the New England and middle states, is cultivated in Europe for its roots, which yield a tonic and stimulating extract, here used chiefly in chronic lung troubles and for some skin diseases. Its pungent taste is also familiar in tonics, and it is a favorite veterinary medicine.

Coltsfoot, the root of the perennial herb *Tussilago Farfara*, and of Comfrey, *Symphytum officinale*, are both in demand for cough mixtures, though the latter is gradually going into disuse. Colombo, the root of the Mozambique plant *Jateorhiza Columba*, is used as a tonic and antiseptic. Other staples are Bitter-root, *Lewisia rediviva*, the fleshy farinaceous roots of which are used by the Indians of the north-west for food; *Berberis Aquifolium*, or Oregon Grape-root, which comes in foot-long pieces and yields a bright lemon-colored bitter powder used for chronic skin diseases; Alkanet, *Alchusa tinctoria*, from the Grecian archipelago and southern Europe, valued for the deep red dye, and said to be used in the manufacture of spurious port wine; Arrowroot, from the West Indies and the Bermudas; Marshmallow, *Althea officinalis*; Lovage, *Levisticum officinale*, for flavoring in cookery and in barrooms; Black Cohosh, the root of the American herb *Caulophyllum thalictroides*; the porous Gentian-root, a remedy of the ancient Greeks and Arabians; the pungent, aromatic rhizomes of Galangal, from the East Indies and China, and used in bitters; Sarsaparilla, the roots of several tropical species of *Smilax*, and which has undergone great changes in reputation; Ginger, *Zingiber officinale*, from the East and the West Indies, and a staple in cookery and medicine; and Curcuma, or Turmeric, the root of *Curcuma longa*. This East Indian plant is used in medicines, condiments, chemical tests and as a dye, producing a yellow color, which by itself is fugitive, but it is largely used in conjunction with other dyes to produce special tints. It is also a harmless adulterant in drugs and spices.

No wide fluctuations in prices or supplies have occurred in recent years, since any scarcity in one locality, or attempt to make an artificial demand, is met by abundant supplies from other sections. The packages are generally bales of from fifty to one hundred and fifty pounds.

New York.

## Plant Notes.

### New Plants in Santa Barbara.

AMONG woody plants of recent introduction that have been blooming here, probably for the first time in the United States, not a few deserve special notice, as they are sure to become permanent denizens of our southern gardens, and some of them are suitable, also, for pot culture under glass in the north. Their wide range of usefulness will hardly surprise persons who are even slightly acquainted with the climate of southern California, when the botanical genera to which they belong and the countries from which they come are considered. Leguminous plants take the lead in number, of course. Without mentioning many Acacias from Australia—some of them quite remarkable—which, perhaps, have already bloomed elsewhere, we have from the same continent *Goodia pubescens*, a low, dense, flat-topped shrub, with light green trifoliate leaves, which for months has been literally covered with good-sized pea-shaped yellow flowers. *Oxylobium callistachys* is another yellow-flowered shrub, with larger flowers in

terminal spikes. It is of upright habit, with foliage nearly as silvery as that of the famous Silver Tree. The Mediterranean basin has contributed several species of *Cytisus* and *Genista*, among them *Genista monosperma*, a prostrate shrub growing in sandy beaches on the southern coast of Sicily, glaucous and wiry, with hardly any leaves and fragrant comparatively large flowers, which are white, with a crimson blotch; *G. Æthnensis*, from Sicily also, found at several thousand feet elevation on Mount Ætna, very like a giant among *Genistas*, attaining the size of a tree, with very fine leafless twigs, in habit like a Weeping Willow, and profusely covered with sweet-scented sulphur-yellow flowers during summer. This *Genista* ought to be hardy at least as far north as Philadelphia, and old specimens exist in the grounds of the Botanic Garden in Paris, as well as at Kew. *Cytisus Palmensis*, from the Canary Islands, has been greatly admired throughout the entire winter for its myriads of pure white, strongly

be one of the most gorgeous flowering trees, with its very long clusters of large scarlet flowers.

To Australia we are indebted for *Hymenoporum flavum*, a near relative of the *Pittosporums*, but with flowers much larger than any of them, white, turning to yellow, and very fragrant; *Carumbium populifolium*, with greenish inconspicuous flowers and rich bold foliage, tinted with metallic hues, like other *Euphorbiads*; *Prostanthera nivea* and *Westringia rosmariniformis*, both belonging to the *Labiata* or Sage family, and white-flowered. We close the list with *Helichrysum diosmæfolium*, a remarkable tree belonging to the *Compositæ*. At present and for weeks it has appeared like a solid mass of silver, the flat umbels of its small everlasting flowers being several inches in diameter. It is said to grow twenty feet high in Australia, and certainly will grow as large in the fertile soil of California, and a very useful plant it is likely to prove to landscape-gardeners as well as to florists.

Fig. 33.—*Iris Robinsoniana* in a California Garden.

apple-scented flowers. This plant is sure to become highly popular in this country for growing in conservatories and for cut flowers as it appears to be in southern Europe. From Chili we have had in flower and fruit *Lithraea molleoides*, somewhat related to the *Sumachs*, a bushy rapid-growing evergreen tree. Its flowers are greenish and inconspicuous, and the fermented berries furnish a highly prized "chicha" or brandy in its native country. From Natal, south Africa, *Dombeya Natalensis* has been blooming during nearly the whole winter season. Its large white flowers are very attractive on account of their fragrance, which reminds one of the *Syringa*. At first glance they suggest a pure white large-flowered *Cherry*. This is a very rapid grower and essentially a winter bloomer, and we hope it is the forerunner in our gardens of many of its congeners. These all have showy flowers and are native of south Africa, and of Madagascar, from which we have already growing vigorously the noble *Astrapea Wallichii*, said to

All the above-mentioned are shrubs or small trees; large-sized trees will take longer to reach the flowering stage. A very remarkable exception we find here in several species of the tropical genus *Ficus*, which often begin to bear "figs"—that is, flowers—when quite young, sometimes before they are two years old from seed. Such is the case with *Ficus Bengalensis*, *F. glomerata*, *F. Indica*, *F. infectoria*, *F. oppositifolia*, *F. religiosa* and *F. retusa*, all from India, and *F. Chauvieri* and *F. Parceli*, from New Caledonia and the South Sea Islands, all of which appear to be quite at home at Santa Barbara.

Santa Barbara, Calif.

*F. Franceschi.*

**IRIS ROBINSONIANA.**—This plant was discovered in Lord Howe's Island by Charles Moore in 1869, and described by Benthams under the name of *Morea Robinsoniana*, but it was not until the spring of 1891 that it flowered for the first time in England, at Kew. This *Iris* is not only noted for

its exceptional size, but it is remarkable from the fact that there is no other species of the genus in the Australian continent nor anywhere nearer than China. The Kew plant was figured in this journal (vol. iv., p. 355), and we now give a picture of another plant (see p. 255), which is interesting because it is probably the first individual of the species which has bloomed in America. It is in the garden of Mr. G. P. Rixford, Secretary of the Academy of Natural Sciences in California, and is said to be sixteen years old from seed.

Iris Robinsoniana is a stately plant with leaves from six to eight feet long and from three to four inches wide, curving gracefully near the ends and of a healthy glaucous color. It is worth growing alone for the beauty of its foliage, which is more attractive even than that of the New Zealand Flax. The flower-scapes are six feet high to the first branches, and the individual flowers open in the morning and close permanently before night. These are four inches across when expanded and pure white, except at the base of the larger segments, where there are lines of golden yellow. Although individual flowers are so short-lived, they appear in succession for a long time, so that a single plant will bear two or three hundred flowers and continue to display them for a month.

For the photograph from which our illustration has been made we are indebted to Miss Alice Eastwood, the Botanical Curator of the California Academy of Sciences.

## Cultural Department.

### Seasonable Notes.

THE height of the flowering season is now here with plants in the hardy flower border, and the unusually wet weather has induced an abnormal growth, with the result that many plants are unduly crowded. I never remember to have seen so luxuriant development of Larkspurs, Poppies, Pæonies, Thalictrums, and, indeed, all such as love moisture, and this includes about all the plants in the borders. We have found it necessary this year to go about and pull out a great number of the Columbines at the close of the flowering time, or as late as it was possible to tell their colors. The tendency in all cultivated plants is toward reversion if left to themselves, and this is soon seen in a mixed border where self-sown seedlings are allowed to grow. Those thus produced are generally inferior to the parents that are the result of much careful cultivation and selection. Especially is this true of Phloxes, Larkspurs and Columbines. The remedy for this is the rigid weeding out of all that do not come up to the desired standard of excellence. If this is not done our gardens soon present the appearance of those that have been left to their own devices for years and are dominated by the old purple Phlox and a few other plants that are equally hard to kill or eradicate.

The Rhododendrons have been specially good this year, better than ever before, and the growth is now in full progress. It is a great deal of labor to go over the plants and pick off the old flower-stems, but, like many other tiresome operations, it pays well and prevents the plants from wasting their energies in seed-production. After such a heavy strain on their resources in flower-production the growths will not be so strong as in other years, and it is, therefore, especially necessary this season to take off the seed-vessels as soon as possible.

Of Tulips grown in the border, and even those that are massed for spring effects, we do not consider it at all necessary to take up the bulbs after flowering; let them remain in the ground and plant some quick-growing annual over them. It will be found that next year the results will be even better than before, and this is especially true of hardy species, though most bulb treatises recommend annual lifting. We find that the dry period we get in fall ripens up with good results—better than if lifting is practiced. If Narcissus have been planted for a number of years, and do not flower successfully, it is because of starvation from crowding, and as soon as the foliage has dried up the bulbs should be lifted carefully, placed separately in boxes, labeled correctly, set in the shade to become moderately dry, and then stored away to be cleaned on some wet days and made ready for replanting in September. It will be found that all the varieties of *N. poeticus* will have live roots attached to the bulbs. This species seems never to be actually at rest, but there is less root-action at the

time the others are dying down than at any other, so that it is safe to lift them with the others, even if there are live roots to be seen. It may seem trivial to tell about careful labeling of bulbs when lifting them, but we have found that with a moderately large collection, or even a small one, it is about impossible, in the first place, to lift every bulb in the ground, and, in consequence, it is better to plant in a different position next time, or mixing will be sure to follow. It also seems about impossible to label all so that they may be rightly distinguished at replanting time. This seems a matter to be easily accomplished, but let him who is sure of it try, and see how his bulbs look at flowering time next year, and the advice will probably not seem so unnecessary.

Any seedling plants that have been raised to add to the borders should be planted without further delay, and it is good practice to have such each year, either for the reserve border or for setting directly where they are to remain. It is also a good time to sow seeds of such as ripen early in the garden, for, if sown now, the plants will be large enough to set out in fall and save a lot of storage-room in the frames during winter and spring. There is no necessity for treating hardy plants under glass at all at this season, or, indeed, at any other, if sowings are made in early summer in carefully prepared seed-beds and transplanting is carried on during showery weather, remembering always the fact that the smaller a plant is, within reasonable limits, when set in its permanent position, the more certain it is to be long an occupant of the garden. Large plants rarely recover from the shift unless they have tuberous roots or some other reservoir to draw upon.

South Lancaster, Mass.

E. O. Orpet.

### Plants in Flower at Wellesley, Massachusetts.

THERE is a fine specimen of *Hydrangea petiolaris* now in bloom on the estate belonging to Mrs. Durant, of Wellesley, clinging, Ivy-like, to the trunk of a large Elm-tree. It grows rapidly. From a small plant seven years ago it now reaches fifteen feet and covers all but the north side of the trunk. The flowers are produced in short-stemmed cymose corymbs, with a multitude of white-stamened fertile flowers encircled with white, large-petaled sterile florets, resembling closely the flower-heads of the other so-called single *Hydrangeas*. It is increased easily from cuttings and layers.

*Raphiolepis Indica*, a charming little bush, is now blooming profusely in the flower garden at Wellesley. It is known as the East Indian Hawthorn, and belongs to the same family. The form and shape of its short corymbs of bloom would suggest the Mountain Laurel, and it is almost as showy. It is a native of eastern Asia, not hardy here, and must be wintered in the same way as tender *Rhododendrons* and evergreens. It is propagated from cuttings of half-ripened shoots.

*Styrax Obassia* is now flowering finely in the grounds belonging to Mr. H. S. Hunnewell. It is one of the most attractive of the many hardy shrubs introduced within late years from Japan, where it is a native of Hondo and Yezzo. The specimen here assumes the aspect of a small tree, in its foliage resembling the Linden. Its attractive snowflake-like blossoms suggest the *Halesias*, and we find that the *Styrax* typifies the family to which both belong. The blooms hang on short stems from the under side of the branches, and are almost completely hidden by dense foliage, but one would almost recognize the plant by its strong Hyacinth-like perfume. It is said to be difficult to establish, and probably on account of this its hardiness has been in doubt. With a suitable location in partial shade and the protection of taller trees, it is here a thrifty and robust-looking plant. It can be multiplied freely from cuttings.

*Benthamia Japonica* (*Cornus Kousa*) is here a small upright-growing tree. One would recognize it at a glance as an ally of our *Cornus florida*, though, coming into bloom later when vegetation is in full leaf, it is not so conspicuous an object. The bracts differ from those of the American species in being ovate-acuminate instead of obovate and emarginate.

Wellesley, Mass.

T. D. Hatfield.

### Rock Garden Notes.

UNDER the influence of our hot summers *Thymus serpyllum* is scarcely recognizable from its appearance in its native habitats. The stems grow from one to two feet long in a season. It flowers freely enough, both flowers and foliage being much lighter in color than in its native haunts. *Geranium sanguineum*, a European species which grows naturally on rocky cliffs, is one of the most reliable plants we have for the embellishment of the rock garden during the entire spring and summer. Seldom do we see it without dozens of its large

pink flowers nestling among the star-shaped leaves. It grows only about ten inches high, and a plant two years old will, under favorable circumstances, grow to about three feet across. Young plants are quickly raised from seeds. North of here *Silene maritima* ought to do well in the rock garden. It behaves well enough with us until about the middle of July, when it succumbs to the hot weather. Seeds are saved of it, however, and sown in the fall and left to themselves in a cool frame for the winter. This species has dense masses of light green foliage, only a few inches high, and the flower is pure white, with a very large inflated calyx.

*Silene Armeria* is desirable for this class of work if kept within proper bounds. In the garden here it would not be long in appropriating most of the space to itself if left alone. It is a very free seeder. The seed of this year's flowers self-sown will come up about the beginning of September and form bushy little tufts before cool weather. The seedling plants come into bloom early in the spring and are followed by others which germinate after the cold weather has gone.

*Pentstemon Torreyi* when not in flower grows about six inches high. The flower-stalks, however, get to be about three feet tall, and although they are flowered sparingly, their bright red color makes a very effective plant.

*Saponaria ocymoides* is almost past blooming; it forms a dense cushion of five-petaled pinkish flowers. The climate here seems to suit it exactly.

*Polygonum repens*, as its name implies, creeps close to the ground, rambling over the stones and filling up chinks in a pleasing way. In the hot months the foliage is of a reddish tinge, but the full crop of flowers is not produced until the fall, when even small plants display myriads of close, round heads of dull pink flowers. With us it is not hardy, but it is well worth saving a pinch of the seed every year and treating the plant as an annual.

*Cerastium Biebersteinii* is past blooming for the season, and the flower-stalks have been cut off; the silvery foliage remains, however, and is attractive all the season. This species does much better with us than the common *C. tomentosum*.

*Spiraea Anthony Waterer* is an excellent companion in the rock garden to the Japanese species, *S. bullata*. All last summer the former displayed its rose-colored flowers, but it is well worth growing for the foliage alone, which is partly variegated with white and sometimes takes on a bright rosy tint.

The *Onosmas* are rather fickle plants to deal with in this latitude, where the soil is baked, and dry soon after drenching rains. Sometimes a plant in full bloom will suddenly die down, root and branch, while others near it will continue in perfect health. They are among the most desirable rock-work plants we have on account of their graceful appearance when in bloom and their delicately scented flowers. *O. stellulatum* is not quite so floriferous as its variety, *Tauricum*. It should be planted in a light airy place where the sun will not strike directly on the root-soil. Pieces of rocks placed around it form a good protection. Cuttings will root under the north side of a wall if kept from wilting by the aid of a glass cover.

An odd-looking plant is *Baptisia perfoliata*, with all the leaves facing outward from the centre and placed perpendicularly on the stalks. It has rather pretty yellow flowers.

Botanic Garden, Washington, D. C.

G. W. Oliver.

### Greenhouse Notes.

THE fancy-leaved *Caladiums* are always considered effective, and since the summer is their growing season they are now a convenient addition to the conservatory. In fact, such an attractive plant as *C. argyrites* is almost indispensable even in a small collection. These plants should now be growing rapidly, and need abundant watering and good soil. Comparatively large shifts in repotting are better than frequent disturbance of the roots. Well-rotted cow-manure is one of the best fertilizers, and from one-third to one-half the compost is not too large proportion for strong-growing varieties. Although much water and a moist atmosphere are required for *Caladiums*, an extremely high temperature and heavy shading should be avoided. Very large leaves may be developed by these means, but it is done at the expense of substance and durability, and such plants will scarcely bear removal to an ordinary conservatory, and still less the exposure of an exhibition hall.

*Gloxinias* and *Tuberous Begonias* are also now approaching their prime, and while they assimilate large quantities of water when in full growth they should not be watered much overhead, or the leaves of *Gloxinias* are likely to become diseased. When well established, clear manure-water of moderate strength is beneficial, given at intervals of about three days.

In the race for large and durable flowers of *Tuberous Begonias*, some interesting and beautiful varieties of a different type seem to have been neglected—for example, *B. Boliensis*, *B. Chelsonii*, *B. intermedia*, *B. Sutherlandii* and *B. Weltoniensis*, all of them easy to grow, readily increased by cuttings and free in blooming.

*Gesneraceous* plants are at their best during the summer; some of them interest for the profusion of flowers in many brilliant colors and some for their rich foliage. The handsome foliage plant of this family is *Drymonia Turialoæ*, of moderate growth, and was probably more common in gardens twenty years ago than now. It is a native of South America, with large oval leaves of much substance and silvery gray in color; the flowers are also quite large and creamy white, and are produced with much freedom from the axils. It propagates readily from cuttings, and the leaves will root as do those of *Rex Begonias*, but are rather uncertain in forming plants.

*Gloriosa superba* is attractive for the conservatory in summer if several bulbs are planted in a large pot and the growths trained informally over a trellis. It is, however, impatient of any disturbance to its roots after growth has begun, and the best method is, therefore, to plant the bulbs in the pot in which they are to remain for the season. A rich, light loam is the best, and after potting water should be given sparingly until the plants have made considerable growth, for sour soil is fatal to success. The best specimens I have seen were grown in a warm house in full sunlight.

For a cool conservatory *Tropæolum tricolorum* is an admirable little vine for pot culture. When the tubers are first planted the directions for watering *Gloriosas* should be followed. A graceful method of training is by means of some twiggy branches from a dead Cedar-tree placed in the pot, on which the slender shoots are permitted to ramble at will. A well-grown plant under this plan is a picture of unstudied beauty.

A collection of native pitcher plants (*Sarracenias*) and hybrids can be made another interesting feature of the garden under glass. A high temperature is not necessary, and the conditions in a *Camellia-house* prove about right. Such kinds as *S. flava*, *S. Drummondii*, *S. rubra*, *S. variolaris* and *S. psittacina* are the best, and favorable conditions for their culture are found in as close an approach as possible to the conditions of a natural sphagnum swamp. The pitcher plant of the Pacific coast, *Darlingtonia Californica*, is also a most interesting species, but, unfortunately, is seldom an entire success under cultivation.

### The Sycamore Blight.

TO THE EDITOR OF GARDEN AND FOREST:

Sir,—I observe that the Sycamore-trees in this section are all losing their leaves. The leaves seem to have been destroyed by some disease or some insect, so that they present a sorry appearance. I should be glad if you would tell me the cause of this defoliation, and, if possible, suggest some remedy.

White Plains, N. Y.

R. A. S.

[This blight of the Sycamore, *Platanus occidentalis*, now so prevalent, which gives the trees such a distressed look, is due to the unusual development of the fungus *Gleosporium nervisequum*. This disease has been at work upon the Sycamores for several years, and, gradually increasing in force, the time has come when either the fungus must be checked or the host will perish. Already many trees have died, and at the present time a large portion of the Sycamores in the eastern states are nearly leafless, and the young branches are dead or nearly so. The fungus develops early in the season, and, attacking the leaves before they are fully grown, causes them to turn brown, and, with their dead young shoots shriveled and clinging to the larger stems, the trees are noticeable for their forlorn appearance. Attacking as it does the leaves and the buds that might otherwise soon produce new foliage, the fungus is particularly destructive.]

It is not improbable that spraying would do something toward saving the trees, but the large ones are not easily covered with a fungicide, and, owing to the trouble and expense, one will not usually spray a tree unless it is a particularly precious one. In such a case the standard Bordeaux mixture could be used with a pump in the same

way as insecticides are applied to large Elm and other trees. The numerous dead branches upon a victim to this blight harbor the fungus, and they should be removed before spraying will have its best effect.

Considering the history of this disease, its insidious nature, the large size of the trees and their almost lifeless appearance, it looks as if heroic treatment with axe and fire was the only way to meet this enemy. I lately saw a long line of Sycamores standing as unsightly victims of disease along a village roadside and thought then that they should give place to trees not susceptible to such a relentless enemy as this anthracnose.]

New Brunswick, N. J.

Byron D. Halsted.

### The Durability of Pitch Pine.

To the Editor of GARDEN AND FOREST:

Sir,—My grandfather settled in Sussex, the northernmost county of New Jersey, in the year 1801, where he bought a small forest clearing and lived in a log-house which was then standing. Some twenty years later he built another house, and since the flooring in the log-house was perfectly sound he used it in part of the new house. This flooring was made of what was locally called Yellow Pine—really it was Pitch Pine, *Pinus rigida*—and I well remember as a boy, nearly half a century ago, seeing the pitch fry out of the boards near the kitchen stove. The original log-house must have been built when nails were expensive, for the boards had in them auger-holes, through which they had been pinned to the sleepers by wooden pins. Half a dozen years ago the part of the house where the old flooring was laid was taken away, and these pine boards were perfectly solid, heavy with pitch and apparently good enough to endure another hundred years of use.

### Exhibitions.

#### Horticulture at the Tennessee Centennial Exposition.

THE visitors who have attended national or state exhibitions in this country which aim to represent the highest achievements in horticulture have usually been disappointed. Of course, the perishable nature of horticultural products makes it difficult to show them well, while in all the large displays the classification has been unnatural and incomplete. Even at the Columbian Exposition, which exceeded in interest and variety previous attempts in this direction, vegetable gardening and the nursery industry were inadequately represented, while the floricultural exhibit was not a true index of the status of that industry in this country. At the Tennessee Exposition the horticultural exhibit is merged into the general agricultural display. This is seen in a structure three hundred feet long by two hundred feet wide, with a central dome a hundred feet high. Here are the state and county exhibits of the products of the farms, orchards and gardens of the south. The prominent feature of the pomological display is the amount of fruit preserved in some transparent liquid and held in glass jars. Of these state and county displays that from Georgia is the most elaborate, the bottled fruit being uniformly well preserved and artistically arranged in irregular pyramids. Many of the jars or bottles are of elaborate design and ornamentation. Various preparations are used for saving the fruit, the fluid often being pure water containing a small amount of sulphurous acid, salicylic acid, or corrosive sublimate. For preserving berries a one per cent. solution of boric acid is the most satisfactory, especially for red and black raspberries, blackberries, red and black cherries, black currants and other red or dark-colored fruits. The Florida exhibit contains a fine display of citrus fruits preserved in sulphuric acid used at the rate of about two ounces to a gallon of water. But, although this preserved fruit makes a fine display, it is from an educational point of view of comparatively small value. The glass jars exaggerate the size of the individual fruits so that they are deceptive, and the method admits of no sampling, so that some of the most important characteristics of the varieties are entirely lost. It is just to say, however, that these exhibits were the centres of attraction in the agricultural building, and that Georgia, Florida, Tennessee and other states which made strong competitive displays in this direction will be amply repaid for all their expense and trouble. Many visitors gained broader ideas of the horticultural possibilities of the south than they had possessed before.

The Tennessee June exhibit of fresh fruit, while meagre, was instructive. But even here there seemed to be an un-

written law that what was lacking in quantity or quality must be made up in fantastic designs.

The Sneed peach was one of the first large fruits to be exhibited. It is said to be a descendant of the Chinese Cling, and is thought by many to mark the introduction of a new type of very early peaches. Following the Sneed in point of earliness came Alexander, and unnamed peaches from various parts of the state were thereafter received almost daily.

Cherries of many varieties have been on exhibition during nearly the whole of June. The earliest varieties were the Dyehouse and Early Richmond, and later the sweet cherries. As showing something of the range of season covered by this fruit as well as the difference in latitude and the short time that elapses between blossoming and maturity, it may be stated that at the time the first cherries were exhibited from Tennessee some varieties were still in bloom in northern Ohio.

There were a few creditable exhibits of nuts, but no adequate representation of what promises to be a profitable industry. The most important and valuable displays were of Pecans, and these native nuts are now seriously attracting the attention of fruit growers.

It is to be hoped that during the progress of the exposition more attention will be paid to the fresh products of the orchard and garden. For example, our native and introduced plums ought to make one of the most varied and attractive exhibits of late summer and early autumn fruit. They can be readily shipped; they keep well on plates and in nearly every state there are varieties that can be grown with satisfaction and profit. There is a wide and growing interest in our native plums, and they seem destined to play an important part in the development of the horticultural possibilities of the interior and southern states. Over fifty varieties were exhibited at the World's Fair in Chicago, and the number has been greatly increased since then.

More attention should also be given to the products of the vegetable garden. The hope of the south lies in a more intensive and more diversified agriculture and horticulture. Small holdings devoted to fruit and garden vegetables must take the place of some of the large Cotton and Tobacco plantations, and then the real economic advantages of the south will not only be appreciated, but improved.

Columbus, O.

William R. Lazenby.

#### Boston Rose and Strawberry Show.

THE conditions for outdoor Roses have been so good this year that every one expected that the Rose show here would excel all its predecessors, but the season was late, and at the date when it was generally supposed Roses would be just at their best, or perhaps going into a decline, the best buds had not really opened. Still, the two hundred vases of General Jacqueminot sent up from Pomfret, Connecticut, by Miss E. J. Clark (John Ash, gardener) were as fresh and good as it is possible to grow them in the open air, and they made a mass of crimson which will not soon be forgotten by any who saw them. Two large tables were filled with Roses from Miss Clark's garden, the best of which were such standard varieties as Fisher Holmes, John Hopper, Mrs. John Laing, Baroness Rothschild, Duchess of Teck, Magna Charta, Paul Neyron, Marquise de Castellane, Ferdinand de Lesseps, Baron de Bonstettin, Madame Gabriel Luizet and the old Centifolia. M. H. Walsh has usually brought a magnificent display from the estate of Joseph S. Fay, and he had the usual number of fine flowers, although there was less variety than in former years, owing to the lateness of the season. The light pink Catherine Souper was superb, and his new hybrid Tea, Lilian Nordica, which last year gained the silver medal, was again shown in first-rate form. It is pure white and seems very hardy. It is a cross between the hybrid Tea, Margaret Dickson, and the pure Tea, Madame Hoste, so that it is three-quarters Tea blood. W. A. Manda, of South Orange, New Jersey, exhibited some of his crosses between Rosa Wichuraiana and such Tea Roses as Perle des Jardins and Madame Hoste which have a fine Tea fragrance and evergreen habit.

The Orchids were unusually good. The prize-winning collection of six plants in bloom was that of Mr. E. V. R. Thayer (E. O. Orpet, gardener), which contained fine specimens of the peculiar *Anguloa Ruckeri*, *Cattleya Mendeli* in a white form with a tinted labellum, *Miltonia vexillaria*, *Cattleya gigas*, *Cypripedium Curtisii* and *C. superciliosum*. Mr. J. E. Rothwell showed a superb *Oncidium papillio*, *Dendrobium Phalaenopsis*, a splendid variety of *Laelia grandis* with bronze sepals and petals and violet lip, and excellent specimens of *Odontoglossum crispum*, *Cattleya Mossiae* and *Cypripedium bellatulum*. W. P. Winsor (Peter Murray, gardener) had also a

noteworthy collection. Among them was conspicuous a specimen of *Epidendrum vittalinum* with sixteen spikes of orange-scarlet flowers, besides *Miltonias*, *Cattleya Mendeli*, *Cypripedium grande* with five stems and fifteen open flowers, and other admirable plants. Mr. W. A. Manda was awarded a special prize for a new form of *Lælio-Cattleya Arnoldiana* with violet sepals and petals, purple lip and yellow throat.

The herbaceous *Pæonies* of Mr. T. C. Thurlow attracted much attention, especially the seedlings, some of which had decided merit. Mr. L. W. Goodell showed two tubs of fine *Nymphæas*, which made a conspicuous feature in the upper hall and proved how much we owe to the skill of Monsieur Marliac for some of the finest early effects in our outdoor gardens. Mention should be made also of Mr. N. T. Kidder's specimen of *Bougainvillea Sanderiana*, which was unusually bright and well flowered, of a few belated *Rhododendrons* shown by James Comley, of the superb Sweet Williams of Mr. W. N. Craig, Taunton, Massachusetts. Mr. Craig also had a general collection of border flowers such as *Carnations*, *Coreopsis*, *Campanula persicifolia*, Foxgloves and many more. Carl Blomberg also had an excellent collection of seventy herbaceous plants, and Mrs. E. B. Richards had a display of wild flowers which included the most attractive kinds now in bloom, and had a distinct educational value.

The strawberries were not as numerous as they have been in former years, but some of them were as big as peaches. Marshall still holds the lead hereabouts, and judging from the magnificent samples shown by Varnum Frost, G. V. Fletcher and C. H. Souther it will not soon be superseded. There was also a good display of vegetables. Among the principal prize winners besides those already mentioned were Kenneth Finlayson, the Bussey Institution, Rea Brothers, J. L. Gardner, Patrick Kane, W. H. Spooner, Miss E. M. Gill and W. C. Winter.

## Recent Publications.

### The Spruce Forests of Maine.—I.

*Third Annual Report of the Forest Commissioner of the State of Maine, 1896.* Augusta: Burleigh & Flint.

That the forestry question in the United States is rapidly emerging out of the hands of the popular propagandist into those of the practical business man is evidenced by several of the publications that have emanated within the past year from official sources. The report of the Forest Commissioner of Maine deserves perhaps the most credit in that it approaches the subject entirely from the business side of the forest owner or forest exploiter. The Commissioner, himself, who fills the position only as an additional duty to that of Land Commissioner, occupies only ten pages of the report, in which he briefly discusses the results of the administration of the forest fire laws. He dwells on the fact that the mere knowledge of the existence of an organized service, evidenced by the "fire notices" widely displayed, has been sufficient to prevent many fires; yet lack of power to act in cases of emergency is complained of, and a fire patrol to follow every railroad train in the dry seasons—which appears a somewhat extravagant demand—is suggested. After a few slurs on the collection of "scientific data" as against "wholesale practical information," he introduces the report of Mr. Austin Cary, who received his first insight into this line of work when employed in the Division of Forestry for the purpose of making measurements of the rate of growth of Spruce and White Pine and afterward made a short trip to Germany in order to gain some rudimentary knowledge of German forestry methods. This report contains so much that is valuable, new, suggestive and desirable to be brought forcibly to the attention of Maine lumbermen that it is a matter of regret that Mr. Cary has chosen a diffuse style and the introduction of much irrelevant and personal matter. In these busy days one objects to working over 200 pages of ore to get out fifty pages of pure metal.

The subject of the report comprises, briefly stated, an investigation into the condition and promise of the Spruce forests of a part of Maine, namely, the portion on the Kennebec and Androscoggin River basins. The report attempts a statement from hearsay of the amount of standing timber; gives a description of the conditions of different

spruce areas, especially after the lumberman has cut them over; and, what is most interesting, furnishes data regarding the growth of spruce with a view of determining what aftergrowth takes place and what method of cutting may be most profitable. Various other matters are discussed in separate chapters, such as the methods of scaling, showing the irrelevancy of the board-measure unit, statistics of lumber cut and boomed in various places, description of the methods of computing growth, calculations of growth of spruce on cut-over lands, waste of logging, etc., all matters of great interest and importance and often well stated.

To briefly summarize the more important results of this investigation, we learn from them that the spruce area of Maine, that which bears spruce in merchantable quantity, is found on the broad, mountainous plateau whose axis runs from the White Mountains across the Rangeley and Moosehead Lakes to Mars Hill at the St. John River, by which the state is divided into a northern and southern slope. The area thus containing spruce is set down as 22,000 square miles. The spruce rarely occurs in pure growths, except on the higher elevations; it is mostly mixed with hardwoods, which form two-thirds to three-fourths of the natural cover, and toward the outer boundaries of the spruce area, with decrease of elevation and improvement of soil, the hardwoods become more and more prominent, finally occupying the ground practically by themselves. The centre of best spruce development, in number of trees at least, is found near the Rangeley Lakes and Moose River and westward to the White Mountains in New Hampshire. Individual development, to be sure, improves with soil conditions, and the best sizes are found on the best hardwood lands; the maximum average dimensions being set at eighty feet in height and two feet in diameter, breast-high.

The estimates by local lumbermen of available spruce standing are given as 1,260 million feet on the Kennebec River with a total spruce-producing area of 1,964 square miles, of which 400 remain virgin, and 3,600 million feet, board measure, on the Androscoggin, in Maine, on a spruce-bearing area of 830 square miles, of which 420 are estimated virgin. Of this latter figure Mr. Cary says that it includes trees down to the smallest log size, and is based on very close economical utilization, while the usual practice in other localities of Maine would bring this figure down to 2,000 million feet. The average stand per acre on the basis of the larger figure would be 6,800 feet, and considering that half the area has been cut over, the average stand for this region, Mr. Cary says, should probably be set as high as 9,000 feet when in natural condition. From the various measurements of actual acre-yields, however, it would appear unsafe to apply this figure to any large area; for the best measured acre, in Grafton, Oxford County, gave with 526 Spruce-trees out of a total of 884 trees of all kinds and a total volume of 2,760 cubic feet of spruce, only 76 trees over eight inches in diameter, which scaled 8,792 feet, board measure, and another acre in the same county with 191 Spruce-trees, out of a total of 535 trees of all kinds and sizes and a volume of 2,220 cubic feet of spruce, gave 63 trees over eight-inch diameter, which scaled 7,352 feet, board measure. The majority of trees, it must be understood, are under a three-inch or at least under a six-inch diameter, while the eight-inch diameter seems to limit the available log size. Another acre in Somerset County, Kennebec drainage, on rocky land, moss-covered and of slow growth, 2,000 feet above sea-level, which, as the author states, represents a large stand for spruce, "as much in fact as could well grow on the ground in this size of trees," "their crowns shading the ground about as densely and evenly as Spruce ever does," contained 346 trees of Pine, Spruce and Fir over three-inch diameter, of which 266 were Spruce with a volume of 2,800 cubic feet, while the thirty Pines, a forgotten remnant, all over eleven inches in diameter, represented 2,040 cubic feet in the yield, each equal to 6,000 feet, board measure, or 12,000 to the acre.

Since the present cut in the regions under consideration is estimated at 310 million feet a year, against a supply of virgin timber of 4,860 million feet, even without an increase in the cut, which is always to be expected, there would appear hardly sixteen years' millable timber in sight under present methods of cutting, and it appears that on the Androscoggin, which represents the larger portion, the cut is even now as close as it could be.

Washington, D. C.

B. E. Fernow.

### Notes.

The latest of Mr. W. A. Manda's hybrid Roses to bloom is a seedling from Rosa Wichuraiana fertilized with the crimson Tea Rose Meteor. The flower is a light pink, very double, and the plant is a strong grower, prostrate in habit and with foliage which remained green all winter and stood out-of-doors without any protection.

*Nuts for Profit* is the title of a little paper-covered book of 150 pages which has been prepared by John R. Parry, of Parry, New Jersey. It contains much useful information collected from many sources on different kinds of edible nuts and their cultivation as adapted to various sections of the United States, besides some useful receipts for preparing nuts for the table in attractive ways.

We have received from Professor William Trelease, Chairman of the Nomenclature Committee of the Society of American Florists, a note, inviting our readers who may have observed cases of misnaming, renaming or any other irregularities in the names of plants which are bought and sold in America, to notify him of the fact by the first of August. It will facilitate the labors of this committee, which reports on the nomenclature of the decorative plants handled by American dealers, if such irregularities are promptly reported and full details are given.

Special consignments of small lots of sugar corn have been received from the south for a month past, but these have been sold directly to a few of the best hotels, and not opened up in the markets at all. On last Saturday the first corn from Delanco, New Jersey, sold in Washington Market at sixty cents for a dozen ears. Cylindrs, the flat scalloped squashes, new celery, peas and cabbage are coming from Long Island now, and on Saturday the excessive supply of southern string-beans was further increased by the first large lots of this vegetable from Long Island. The round sort known as Refugee brought double the price of the less tender flat kinds. Large fleshy Windsor beans are also now in season. Occasionally Peach tomatoes, from California, so named from their striking resemblance to that fruit in shape, color and bloom, are seen in the wholesale markets, where they seem mainly to be regarded as a curiosity. Lima beans are expected daily from the south, and when these and new sweet potatoes are in the market the entire list of fresh vegetables will be complete. Asparagus continues one of the staples, with cauliflower, cucumbers and eggplants. All vegetables are coming in from southern and neighboring states in immense quantities, and although they are of excellent quality the urgency of the demand in the wholesale markets does not keep pace with the increasing supply, so that while the consumer pays an average price, the grower finds his profits swallowed up in expenses for packing, transportation, commissions and the like.

The trays of the Italian and Greek fruit vendors which line the curbs of sections of our downtown business streets are now stocked with a wide variety and indicate the range there is to choose from. Each tray offers but one sort, and for a week past peaches, from California, have been abundant and attractive and of unusually good texture and flavor. Apricots are also plentifully seen, with trays of Le Conte pears, bananas, plums and cherries. The bright and showy light Royal Anne cherries are almost as large as the smaller Botan plums now coming from Florida, and Black Tartarian cherries are almost as handsome in their rich dark color and large size. White and red currants from the Hudson River section of the state, and raspberries from New Jersey, are seen in large quantities. The supply of strawberries is beginning to lessen and is mainly from this state. Huckleberries and cherries are coming from as far north as New Jersey and New York, and blackberries from Maryland. Northern Spy and Russet apples from last year are still in market, and five barrels were exported so late in the season as last week, when considerable quantities of green apples are being received from North Carolina. In the fancy-fruit stores last year's P. Barry pears are also yet in stock. Niagara grapes, watermelons and muskmelons are

all to be had, the latter mostly small. Some muskmelons from New Orleans are of extra-large size, however, and those of spicy flavor readily command \$3.50 for a box of six fruits in wholesale lots, while some of the same size, lacking in quality, bring but \$2.00. Some really good fresh figs came into this market last week from California. They were large, plump, and with an attractive clear purple skin, and while, of course, their flavor had suffered somewhat from the long journey in a refrigerating car, they were pronounced delicious by the few persons who could afford to buy them at \$1.00 a dozen, and \$2.00 for the choicest.

Everybody in England has lately been engaged in summing up the progress of the kingdom during the sixty years of Queen Victoria's reign, and *The Gardeners' Chronicle* publishes an interesting résumé of the progress which has been made in horticulture during this period. In regard to Roses in particular we are reminded that when the young Queen was crowned the Hybrid Perpetuals had not yet risen to the dignity of a class, Tea Roses were almost unknown, the dwarf Polyantha Roses had not been introduced, and what are called Summer Roses were about the only adornment of gardens. The advance in Hybrid Perpetuals, Roses of exceedingly mixed origin, has been most extraordinary. The hybrid China Rose, Gloire des Rosomanes, may have been in existence at that time, but General Jacqueminot, which is a probable seedling from it, did not appear until as late as 1853. La Reine was one of the introductions of Laffay as early as 1839, but the great number of exhibition Roses which we know to-day were not produced until the sixties or seventies. Of Tea Roses, Safrano and Bon Silene date from 1839, while Devonensis, the earliest English-raised Tea, was sent out in 1841. All the great Tea Roses have appeared since Niphetos was sent out in 1844. In the Noisettes, which, as is well known, are of American origin, there has been great improvement, especially since the introduction of Tea blood into the original stock. Of course, the hybrid Teas are of comparatively recent origin, while the Polyantha Roses, with such developments as the Crimson Rambler, are all modern additions to our gardens. Rosa rugosa came from Japan many years ago, but R. Wichuraiana and other single-flowered species are later additions to our garden plants, while the efforts to hybridize the Sweetbrier, Rosa setigera, and the single-flowered Roses generally with other classes were begun but yesterday. It may be added as a good tendency of the times that the single Roses which were comparatively neglected in the early years of the Victorian era are now assuming the position they deserve as garden plants of the highest decorative value.

Three plants belonging to the Mustard family, which are weeds in the fields of western Europe, have been reported within the past four years in several localities in the northern United States and Canada. The first of these is Gray Berteroa, Berteroa incana, an annual with a rosette of leaves at the base, numerous white flowers and seed-pods a quarter of an inch long divided into two cells, each of which contains six seeds usually. These seeds are brown, of about the same size and weight as those of Red Clover, and therefore difficult to separate if the two become mixed. Since an average Berteroa plant contains five thousand seeds, while a Red Clover plant produces in two years about one thousand, it is very easy to see that if only a small per cent. of the weed seeds germinate they will soon be much more abundant than the Clover. Of course, no Clover or Grass seed should be gathered from fields infested with the Berteroa. Wherever a few plants are found they should be pulled up by hand, and where they are abundant they should be mowed as often as the flowers appear. The Hare's-ear Mustard, Conringia orientalis, is another slender-branching annual, smooth and grayish. It is already in the grain-fields of Manitoba, and the seed of wheat and oats in that region ought to be carefully cleaned. Flaxseed from infested fields should not be saved for sowing at all. It is a conspicuous plant, easily recognized, and it should be pulled or mowed as soon as seen to prevent establishing it in new localities. Its white flowers are handsome enough for the flower garden, and its tender leaves, with a mild mustard flavor, make a good salad, but if ever used in the garden none of the seeds should be allowed to fall. Ball Mustard, Neslia paniculata, so called because its pods, about one-twelfth of an inch in diameter, are nearly spherical, is the third weed. It does not produce many seeds, and it has certainly spread slowly, because it has been known in America for fifty years. It has become abundant and troublesome in the grain-fields of southern Manitoba, however, and it seems to be developing an increasing ability to spread. These plants are described and figured in a circular prepared for the Department of Agriculture by Lyster H. Dewey, assistant in the Division of Botany.

## The True Function of City Parks.

THE President of the Board of Education of this city has made a proposal to the Board of Public Parks, of which this is the essence: "There are few among our public-school children who are able to recognize when they see them the various grains, the production of which constitutes so large a portion of the wealth of this country. I suggest, therefore, that you prepare a small piece of ground in Central Park, say, two hundred feet long and fifty wide, and divide it off into distinct lines so that there can be sowed in the first division of the space wheat, in the second oats, in the third barley, in the fourth rye, and in the fifth corn. The crops can be allowed to grow until ready for harvest, when they can be cut, laid in shocks and sheaves, and allowed to remain for such a time as would be desirable for the continuance of this object-lesson."

Persons who are familiar with the history of our city parks are not surprised at any attempt to divert them from their primary purpose. Long before the lower half of Central Park was completed the Park Board was urged to display in the lake a model fleet of the different kinds of sailing craft, so that school children could learn the difference in build and rigging between a ship and a schooner. An eminent educator petitioned that the north meadow should be laid out as a map of the United States, with the chief products of each commonwealth growing in its proper latitude and longitude as an object-lesson in home geography. Half a dozen years ago an elaborate scheme was devised in Boston for locating small insectaries, aquaria and zoölogical collections in different parts of that city park system, with each group of animal life surrounded by the flora of that portion of the world in which it flourished. And since catalogues could never grow as rapidly as these museum collections would increase, it was advised that educated persons in different branches of biology should be stationed near each collection to answer questions and give instruction to visitors.

The trouble is that the zealous people who wish to transform the parks into places for public education and scientific research, or devote them to military parades or to public meetings for the advancement of religion or any

other good cause, forget that the primary purpose of a rural park within reach of a great city is to furnish that rest and refreshment of mind and body which come from the tranquilizing influence of contact with natural scenery. Of course, people, young and old, can skate on the lakes in the winter, and listen to music which is provided in the summer, or play golf or ball where arrangements for such games are possible, but all these additions when they are successful are made subordinate to what should be the controlling purpose in the design and maintenance of such pleasure-grounds. Anything which interferes with the restful quality of the scenery in so far destroys the highest value of the park.

There is no need of offering specific objections to the proposal of President Hubbell. We dissent from his opinion that this growing crop of grain would be "ornamental," and we apprehend that if he would reflect upon this point he would agree with us that a square piece cut out of the turf in the north meadow, for instance, and planted in a checker-board of different colors of grain or stubble would not enhance the quiet beauty of the scenery. But if a beginning was made in this direction, why stop with five patches? Any one can see corn or oats or rye growing in their season within the city limits, and why not add buckwheat, the sorghums and millets, which are not so well known, but which are of growing importance to our agriculture every day. Besides these there are important leguminous forage plants worth knowing, and there are few city boys who can distinguish Kentucky Blue Grass from Red-top. Then there are Flax and Hemp and other fibrous plants, and no end to the different varieties of vegetation which enter largely into the economies of our every-day life. But the simple fact is that a collection of agricultural and economic plants is not a park, and it cannot be made into a park any more than a museum can develop into a library. The ideas are distinct and they may be conflicting. No doubt, education is a good thing, and scientific research is a good thing, but refreshment of mind and body is also a good thing, and it is an especially desirable relief from the nervous eagerness and intensity of the life in modern American cities. Why not leave the parks to furnish this rest, instead of turning them into cheap adjuncts of the university extension movement?

## Forestry in Pennsylvania.

WE are too often overwhelmed with discouragement because honest and persistent efforts at disseminating rational views on the subject of forestry seem to produce such meagre results, but it should be remembered that the enlightenment of public sentiment is slow work, and while the fruits of educational labor are not always manifest at once, the seeds of good ideas may nevertheless be germinating for future harvests. Half a dozen years ago no sane man would have hoped that any one of the forest laws enacted by the last Pennsylvania Legislature would pass. But many earnest men and women have been writing and talking and memorializing until a public opinion has been developed which makes almost any good legislation in this direction possible. It is very plain, too, that the report of the Forestry Commission which was published last year has done much educational work in that state, while the influence of its Forestry Bureau, created the year before, has been constantly exercised for good.

The act which will probably give delight to the greatest number of intelligent people in the country is one which creates a great reservation at the head of each of the important rivers of the state, the Delaware, Susquehanna and the Ohio. Each of these reservations contains 40,000 acres or more, and since the bill passed the Senate with only one negative vote, it is more than probable that they will be greatly extended hereafter, and that this measure is the beginning, not only of systematic protection of forests, but of a conservative practice which will provide increasing forest supplies for the future. It

is a significant fact that this bill was introduced into the House of Representatives by an active lumberman, and was supported by others who have made fortunes in the same industry. The Governor of the state, who has showed before this that he is alive to the necessity of forestry reform, signed the bill with promptness and has expressed himself as desirous to be an active promoter of the scheme which the law makes possible.

Another act of equal importance, perhaps, encourages private owners to preserve their growing forests by remitting taxes on such property. The law provides that in consideration of the public benefit to be derived from the retention of timber-trees, the owners of land which carries not less than fifty trees to the acre, each tree being at least eight inches in diameter at a height of six feet above the ground, shall be entitled to receive annually, so long as these trees are maintained in sound condition, a remission of four-fifths of the taxes assessed on such land. Besides these, there are other laws for the suppression of forest fires and for the protection of timber land from depredation, which are not only good in themselves, but which are particularly significant as indicating the temper of mind which has made such legislation possible.

This action of the Pennsylvania Legislature is certainly most encouraging. It means that the people of that state have learned a good deal in the last ten years on this subject, and the fact that there are now in both houses of the Legislature standing committees on forestry, shows that the will of the people is making ready to express itself in law. It has not been in vain that such an officer as the Commissioner of Forestry was appointed and that a report on the condition of the woodlands of the state has been published and disseminated. This means education, and it is more than gratifying to know that the Legislature has provided for publishing 17,000 copies of this instructive report to replace those which were lost in the fire which ruined the state capitol. The state has begun to frame good laws for the protection, the preservation and the enlargement of its forests. The educational work should be kept up with vigor until an intelligent public sentiment is developed which will enforce all these acts up to the full spirit which inspired them.

#### Private Forestry and State Forestry.—IV.

IT is apparent that any state action in the direction of forestry will cost money. But the investment is sure to be profitable, partly through the influence of forestry on climate, water-supply, etc., partly by the annual growth of timber on the state lands.\* I would not advise, in general, any haste in harvesting tree-growth from the state forests. The reason lies in the condition of the lumber industry. This great branch of the national resources must be preserved. That industry is now taking the timber from private lands. Opening such parts of state forests as are well timbered to axe and saw would tend to reduce the value of the stumpage of trees, and the destruction of forests would be accelerated. State forests as well as private would become bare of high-grade timber trees after the lapse of a few decades. But it goes without saying that a small part of the state forests might safely be put under economic forest management at an early date in order to gather experience.

The golden rule of state forestry at this time is, "Be quick in securing forests, firm in protecting and slow in using them."

Economic forest management cannot be established at a trifling expense.† Apart from the outlay for forests and

foresters, a large sum must be spent for the creation of more permanent means of transport, such as wagon roads, pole roads, tramways, flumes, cable roads, etc. There is one method of transportation, however, that should not be adopted, namely, that of driving logs down to the floatable rivers by means of splash dams. Clearing the creeks for a splash means doing away with any obstacles or obstructions to the watercourse. For obvious reasons this should be avoided under state forest management. Any clearing of creeks accelerates the collection and downflow of precipitations. Such forestry, instead of preventing floods, would facilitate them; instead of regulating the water-supply it would endanger its regularity.

Another outlay to be incurred before economic forest management can begin is for a working plan. A working plan is a report consisting of two parts. The first part is a description, based on a topographical map of the growing stock, its productiveness, the existing and the possible means of transport, the most economical use to be made of the products, and the possible methods of regeneration. The second part is a plan of future operations, so arranged as to apportion the expenses and revenues over a series of years. It indicates what parts of the forest are to be cut over first; what parts, if any, are to be improved; what parts, if any, are to be replanted; what roads, etc., are first to be made. This work is not as inexpensive as might appear at a first glance, especially in a country in which forestry is entirely new. Mistakes at starting are unavoidable, but their number and importance can be lessened by laying down a well-considered working plan, and the larger the total area the smaller will be the expenditure per acre. A network of footpaths must be traced out as an aid to the work of protection, and, where necessary, occasional strips should be kept free of combustible matter. Of course, under favorable conditions, the expenditure for establishing economic forest management will be small. Where there are railroads or rivers running through the heart of the district, where timber can be hauled to the railroad or river on sledges, where there is a road system, where there are maps of sufficient accuracy, where there is a tolerably uniform growth of timber, it is easy to establish economic forestry. Beware, however, of plunging into forest work; in forestry, mistakes once made can only be corrected, if ever, after the lapse of a tree's life.

There is no need of stating that forest management can scarcely be expected to furnish an immediate revenue in districts where lumbering does not pay. Even in such districts, however, there is some return from forest protection; it is dormant, latent, it is not in available cash, it is added to the original stock of capital without any possibility of separation from it. The return consists in the improved quality and increasing value of the growing stock and of the soil. In a country in which the value of stumpage is rising rapidly, forest preservation is sure to pay.\*

I am not sure that I have expressed my convictions in the forest question with sufficient clearness, and should like to summarize the principal points:

State forestry must come into play where districts administered solely with a view to the highest money return have ceased to act as a "barrier against losses."

Private forestry † in this country can be made remunerative, and therefore feasible, under a certain set of circumstances (a reduction of taxes on second growth and a protection against fire by state guards), the creation of which is the duty of the Government.

Biltmore, N. C.

C. A. Schenck.

\* Report of the United States Division of Forestry, 1892, page 307.

† There is a peculiar kind of private forestry already in existence here and there, which might be called park forestry. Park forestry, for landscape purposes, or for the sake of game preservation, voluntarily sacrifices a more or less considerable share of the money return attainable under exclusive economic forest management. It allows some trees to stand that ought to be felled and sold, and that merely because they are picturesque or because they bear seed which affords food to the game. Park forestry builds roads, not merely to facilitate the transport of forest products, but also to furnish pleasant drives and rides. It goes to the expense of planting varieties of trees in places where regeneration from self-sown seed would cover the ground in the course of time. It further allows the deer to nibble off the young shoots of trees. Such management is forestry because its main object is the forest. But it is not economic, financial forestry.

\* The forest guards acting as fish and game keepers at the same time, in many cases considerable revenue can be derived from fishing and hunting leases. The leases should run for a score of years and should comprise one or two ranges each. Their wording should be such as would warrant the maintenance of a suitable stock of both game and fish, under the control of the rangers. There are plenty of sportsmen in the United States who will gladly pay as much money for the exclusive right of fishing and hunting on a reserved range as the annual salary of the ranger amounts to.

† Report of the United States Division of Forestry, 1892, page 314.

## Pomegranates and Oleanders in California Villages.

NOVELISTS, when arranging their scenery, are apt to describe all villages as embowered in roses. As a matter of fact, hardly two villages in this state are similar in the character of their gardens, because soil, climate, situation and many curious accidents determine the kind of beginnings these gardens make and the lines of their development. Some of our mountain towns are noted for their Asters, others for their Dahlias, their Campanulas, their Balsams or their Carnations. One old mining camp grew to be a maze of white Lamarque Roses long before it was deserted. A little river-crossing in Shasta, where three or four log cabins clustered together, was once as fine a Geranium garden as America could then show. But I have been particularly interested in the use that is sometimes made of easily grown shrubs, cuttings of which are passed from neighbor to neighbor until the whole district has one characteristic garden plant. Among such are the Pomegranate and the Oleander.

There is a little town of the Sierra foot-hills named Ione, in Ione Valley, Amador County. Mountain streams and irrigation ditches cross it, and great groves of Oaks give dignity to the landscape. The pioneers planted many Apple, Pear and Cherry trees in irregular groups near the streams, so that one sometimes sees very large specimens of these fruit-trees, unpruned and neglected, but still bearing crops. The newer orchards and vineyards are much more profitable, though not half so attractive. The heart of the valley is almost a swamp. Giant Willow-trees, expanses of Marsh Grasses and Cat-tails, with impassable thickets of wild Blackberry vines, form a strange contrast to adjacent hills of white or red clay thickly clad with various species of Rhus, Ceanothus and Manzanita, with here and there a solitary Pine, the sentinel of some peak. The comparative isolation of the valley seems to have developed neighborliness and touched all Ione's gardens with an air of fellowship. Years ago, as one plainly reads the story, some one must have brought a scarlet-flowered Pomegranate from Sacramento and planted it. Cuttings were freely distributed, so that now, as I rode through the town in early June, I could not but admire the predominant Pomegranate color. Almost every garden has this royal shrub, standing in many cases twelve or fourteen feet high, and loaded with flowers, and fine specimens guard gateways or make the centrepiece of many a sheltered, sunny lawn, under the bluest of blue skies.

There are other foot-hill villages of California noted for especial flowers, the charm of which will long linger in one's memory. "There's them flowers you call Oleanders all over Douglas Bar," said an old pioneer woman to me up in Trinity County. "When me an' my ole man druv out here from Missouri I carried one in a tin can and watered it every day. Then, when we settled down in this camp, I rooted slips in bottles for everybody that wanted them. We didn't hev eny other kind of flowers except the wild ones till we got a schoolhouse. Then the teacher brought some Marigolds over the range. Next we hed a white Rose thet grew from a slip thet the stage-driver brung from Shasta. We thought it was awful pretty. 'Bout the time the war began we got some Morning-glory seed, and now, ef ye find one of these Oleander-bushes eneywhere in a cañon all by itself, look 'round, and close by there'll be the wreck of an ole cabin, a chimbley, or mebber a gravestun, to mark some forty-niner's home. Some of them very bushes that I rooted in bottles is growing thirty miles away in the brush, with nobody left 'cept me to say anything about it."

Douglas Bar was a mining village beside the Trinity River, in the midst of Pine forests, and though it had many quaint and sweetly old-fashioned flowers in its sloping and terraced little gardens by the time I first saw it, the one preëminent floral fact was that Oleanders grew there in riotous profusion, as single tall specimens, as hedges, in clumps and masses of royal color to which everything

else was subordinated. No one in Douglas had ever had the moral courage to own a garden without an Oleander. But this simple, oft-repeated element gave the visitor a pleasure hardly to be put into words; it glorified the land all summer long even more than those scarlet Pomegranates glorify the valley of Ione.

Niles, Calif.

Charles H. Shinn.

## The Agricultural Prospects of Alaska.

THE recent action of the Department of Agriculture, in sending a commission to Alaska to examine into, and report upon, the agricultural prospects of our northern province, may possibly have the effect of causing some people to infer that farm products can be grown successfully there, and for the information of such I give my experience while a resident there. Having lived for five seasons in Alaska, I would say that in my judgment the territory is wholly unsuitable, and in the nature of things must always remain unsuitable, for agriculture in the proper sense of that term. This unfitness is neither due to cold nor to the northern latitude, as most people suppose; on the contrary, the climate is very mild between the coast range and the ocean—the temperature at Sitka not being very materially lower than that of Portland, Oregon—while the long summer day of northern latitudes compensates for the shortness of the season. The two causes that militate against agriculture in the territory are paucity of soil and humidity of climate.

The lack of soil is remarkable. The surface of the country is generally a mass of moss-covered rocks, from the seashore to the mountain sides, the only exceptions to this rule being the sphagnum marshes, which are too wet to produce cultivated crops; the alpine meadows, which are too elevated for this purpose, and the few deltas and alluvial strips which have been deposited about the mouths of the larger streams. The latter and a few humus-covered spots on the shores of some of the bays and inlets are the only places available for agriculture in the whole territory. Where these patches have a south-western exposure and are properly drained, or the slope is sufficient for them to drain naturally, the long summer day of the region is so favorable that garden vegetables can be raised to some extent, but the raising of hay or grain is out of the question; it could not be harvested owing to the humid climate, even if it could be grown successfully.

As many persons may be desirous of knowing just what can be grown successfully, I herewith give, in alphabetical order, my experience with various grains, grasses and vegetables:

Barley does not ripen. Beans (Snap) do well. Beets give good results if the soil is drained. Cabbage can be raised, but it will not head. Carrots can be grown fairly well. Cauliflower does well in a dry season, but the heads are small. Clover I did not succeed with, possibly because the spot on which I tried it was unsuitable. Corn does not ripen at all, and only produces an abortive grain. Fruits (native) nearly all yield an abundant crop; the native Strawberry only does well on sandy spots, either alluvial or glacial; Salmon-berry, *Rubus spectabilis*, grows luxuriantly; Cloud-berry, *R. Chamæmorus*, is generally plentiful on the sphagnum marshes, but is occasionally caught by frost and proves a failure; the five native Huckleberries, *Vaccinium parvifolium*, *V. ovalifolium*, *V. arbuscula*, *V. sp.* and *V. sp.*, are excellent and of fine flavor and always yield a large crop; the Cranberry, *Vaccinium Oxycoccus*, is scanty; the high bush Cranberry, *Viburnum pauciflorum*, is abundant and good; the Currants, *Ribes acerifolium* and *R. bracteosum*, yield a large crop, but are not of good flavor; the Service-berry, *Amelanchier alnifolia*, is scarce, but good, and the native Crab-Apple, *Pyrus rivularis*, is only good in favorable seasons.

Of the introduced fruits the Currant and Gooseberry are the only ones I found worth trying, but it is quite possible that some of the early varieties of Apples would do well if

grafted on the native Crab-Apple ; just as the introduced Cherries in Oregon, when grafted on the native wild Cherry, *Prunus mollis*, excel any grown on their own stock.

The Grasses all grow luxuriantly and make excellent forage ; the opinion expressed by some that cattle will not eat the native grasses is a mistake, the plants which they reject being some of the Sedges (*Juncaceæ*), which many people do not distinguish from the true Grasses. Lettuce does remarkably well, and by sowing at intervals it can be had ready for use the greater part of the season. Oats will ripen, but cannot be harvested. Onions will not do well when grown from seed, but when grown from sets produce very acceptable "green onions." Parsnips grow fairly well, but are small and not of first-class flavor. Peas of the early varieties do remarkably well, and far exceeded my expectations. Potatoes, though very late in sprouting some seasons, grow rapidly, and when planted in well-drained soil give a fairly abundant crop and of fine flavor. They have been cultivated for a century or more by the Indians (*Haidas*) on Prince of Wales Island. Radishes proved to be excellent, and when sown at intervals can be used all through the season. Rhubarb grows abundantly, but not of quite as good a flavor as when grown farther south. Rye will not ripen. Timothy grows luxuriantly, but cannot be harvested. Turnips, though not large, proved to be a good crop and of fine flavor. Wheat grows a good straw and well-developed head, but will not ripen, and could not be harvested if it did mature on account of the prevalent rains and continuous cloudy weather.

The quantity of rain which actually falls does not give a non-resident a proper idea of the impediments to agriculture in the territory, as the number of rainy days in proportion to the amount of rain is much greater than in the middle or eastern states, while the proportion of cloudy days and the consequent difficulty of harvesting a crop is still greater. To better illustrate this fact I submit the following record of precipitation and number of rainy days during the months of June, July and August for the years 1892, 1893, 1894 and 1895 :

	1892.		1893.		1894.		1895.	
	No. of rainy days.	Rain in inches.	No. of rainy days.	Rain in inches.	No. of rainy days.	Rain in inches.	No. of rainy days.	Rain in inches.
June .....	19	3.62	22	4.60	21	3.57	21	6.77
July .....	23	6.81	22	9.26	20	8.97	17	5.85
August.....	28	10.61	24	12.70	19	9.49	26	8.68
Total for three summer months.....	70	21.04	68	26.56	60	22.03	64	21.30

This, however, being only for the three summer months, is still considerably below the average annual precipitation, which is 111.72 inches.

Even if the region was fully soil-covered, the surface of the country is so precipitous and uneven, and the annual rainfall so great, that the soil would soon be washed into the gulches and ravines if the hillsides were once denuded of their forest covering. The forests, while containing some valuable timber, such as the Tideland Spruce (*Picea Sitchensis*), Pacific Red Cedar (*Thuja plicata*) and Alaska Cypress (*Cupressus Nootkaensis*), are not nearly as extensive as many people suppose, and in any event will only be sufficient to supply the local demand.

In conclusion I would say that the territory can never, under any circumstances, be a field for the farmer, and, although the grasses are abundant and nutritious, it cannot be utilized for stock-raising, owing to the long winters.

Its only industrial possibilities are for the miner, the salmon-canner and the fur-hunter.

Portland, Ore.

M. W. Gorman.

Among works of art of every class statues most rarely give permanent satisfaction, and if they are awkward, ungraceful or unsuitable for the situation in which they are placed, none are so obtrusive and unsatisfactory.—*Calvert Vaux*.

Foreign Correspondence.  
London Letter.

*WATSONIA IRIDIFOLIA O'BRIENI* is now finely in flower in an unheated frame at Kew, the spikes being over a yard high, and the flowers two inches across and snow-white. It is in every sense a first-rate garden plant and should prove a profitable investment for growers of bulbs for the wholesale market. It is better than many *Watsonias* in its behavior under cultivation, for it has flowered every year at Kew since it was first obtained in 1891. I have already described it fully in *GARDEN AND FOREST*, but I may repeat here that it is very similar to *W. rosea* in general appearance, with larger flowers than any other *Watsonia*, and very fragrant. I have seen spikes of it four feet high with five or six branches and bearing from thirty to forty flowers open at one time. It ought to be a good plant for forcing to flower in spring. *W. Ardernei* is another name for it.

*STENOMESSON AURANTIACUM*.—This is an elegant summer-flowering bulbous plant which until lately has always been grown in pots under glass, but which has proved quite at home in an outside border against a warm house, where it is now flowering nicely. It has globose bulbs about an inch in diameter, linear oblong leaves produced along with the flowers, scapes from nine inches to a foot high, each bearing an umbel of about six flowers, which expand in succession, two or three being open together ; they are nodding funnel-shaped, an inch and a half long, and of a rich orange-red color. It grows in the Andes of Ecuador at an elevation of 13,000 feet. The Coburgia section of *Stenomeson* includes several beautiful flowered species, which, however, are somewhat difficult to flower under cultivation, although they grow and multiply freely enough.

*HELICHRYSUM ROSMARINIFOLIUM*.—There is no more attractive shrub in June than this in the warmer parts of the United Kingdom. In Ireland, especially the south and west, it forms a bush six or eight feet high, and when in flower it resembles a snow-laden shrub ; hence the name by which it is called there, namely, Snow in Summer. It is now flowering well against a wall at Kew, having withstood the comparatively mild past winter ; as a rule, however, it is either killed or cut down to the ground by the winter cold experienced at Kew. It is better known, perhaps, by the name of *Ozothamnus*. It is a native of Van Dieman's Land and was introduced into England about seventy-five years ago.

*OSTEOMELES ANTHYLLIDIFOLIA*.—This plant passed through the cold of last winter uninjured in a sunny position against a wall, and is now bearing numerous clusters of white May-like flowers. In countries where it would be quite hardy—it is not hardy at Kew—it forms an elegant bush or small tree with thin branches, pinnate leaves, more or less persistent, and flowers which in size of umbel, arrangement and color are not unlike those of the *Amelanchier*, to which genus *Osteomeles* is closely allied. Although well known to botanists as an interesting shrub of remarkable distribution, it was not introduced into cultivation until about five years ago. It is easily propagated from cuttings and it forms a nice pot-plant for the cool greenhouse. A second species, as yet unnamed, has lately been introduced into the Jardin des Plantes, Paris, and from thence to Kew.

*CEDRUS ATLANTICA AUREA*.—This well-known variety of the Atlas Cedar was well shown before the Horticultural Society by Messrs. Veitch and obtained a first-class certificate. In soils suitable to it, this golden-tinted form is likely to prove an attractive conifer and a worthy companion to *Cedrus Atlantica glauca*, of which there are some beautiful specimens in English collections.

*CELMINIA MONROIL*.—I lately noted this as being in flower at Kew. Some plants of it were exhibited by Messrs. Veitch & Sons at the last meeting of the Royal Horticultural Society, where it was awarded a first-class certificate. It was looked upon as a new introduction by most of those who saw it.

Fig. 34.—*Lonicera gracilipes*.—See page 266.

1. A flowering branch, natural size. 2. A fruiting branch, natural size. 3. Longitudinal section of a flower, enlarged. 4. A fruit cut horizontally, enlarged.

Roses.—Collections of single and semidouble Roses are now frequent features of our plant exhibitions, and I am told by the nurserymen that these forms are growing in popularity at such a rate that it is difficult to supply the demand for them. The Penzance Briers have, no doubt, had some-

thing to do with this run on single Roses, and the large collection of all kinds of species and first crosses of Roses cultivated at Kew has, no doubt, also had some influence upon horticultural taste in this respect. The Rose garden at Kew—a large sunken area laid out with tree-roots with

grass walks among them, planted with masses of all kinds of showy species and subspecies—is now a great attraction. Nothing could be finer than Crimson Rambler, Carmine Pillar, the various forms of *Rosa lutea*, *R. Indica*, *R. damascena*, *R. involucrata*, *R. moschata* and *R. rugosa* when planted in bold masses either as in this Rose garden or in conspicuous places on lawns.

**VANDA AGNES JOACHIM.**—This is a hybrid raised at Singapore a few years ago from *Vanda teres* and *V. Hookeri*. It was named and described by Mr. Ridley, and afterward passed into the collection of Sir Trevor Lawrence, by whom it was shown in flower at a meeting of the Royal Horticultural Society, receiving a first-class certificate. Apparently it has inherited the robust free habit of *V. teres*, and shows none of the spindliness of the other parent. It bore a spike nearly two feet long carrying nine flowers and buds, which are like those of *V. teres*, but the lip has a larger midlobe, and the color of the whole flower is of a softer pink, with tinges of purple and yellow. It cannot be considered much superior to *V. teres* as a garden plant, but it is interesting as being the first hybrid *Vanda* raised artificially.

**LARGE-FLOWERED CATTLEYAS** are becoming abundant. They were numerous at the Temple Show, and at the last meeting of the Royal Horticultural Society four new ones obtained certificates. The names of these are noteworthy: *Lælio-Cattleya Dominiana*, var. *Empress of India*; *L.-C. Our Queen*; *Cattleya Mossiæ*, *Empress of India*, and *C. Mossiæ*, *In Memoriam*, Richard Curnow. The last-named is, perhaps, the largest variety of *C. Mossiæ* known, and its colors are equally rich and striking. It was shown by Messrs. H. Low & Co., and the name is intended to commemorate one of their collectors. Among other good *Cattleyas* with bad names exhibited at this meeting were *Lælio-Cattleya Canhamiana Langleyensis*, *L.-C. Canhamiana*, var. *Sappho*, and *L.-C. Canhamiana*, var. *Iolanthe*. Judging by the large number of handsome forms of *C. Mossiæ* which have been exhibited in London recently, some new collecting ground must have been discovered for it. There is no more beautiful *Cattleya* than a good *C. Mossiæ*.

London.

W. Watson.

## New or Little-known Plants.

### *Lonicera gracilipes*.

**THIS** bush Honeysuckle is a native of Japan, where it is not uncommon on the borders of mountain forests in central Hondo, and has been cultivated for ten years in the Arnold Arboretum, where it is perfectly hardy and has attained the height of four feet, forming a broad vigorous shrub.

*Lonicera gracilipes*\* (see fig. 34, on page 265 of this issue, made by Mr. Faxon in the Arboretum) is a shrub with erect stems and spreading branchlets at first pale yellow-brown and conspicuously enlarged at the nodes, and at the end of two or three years becoming dark gray or grayish brown. The leaves are broadly ovate, rather abruptly contracted into short points, entire, thin, light green on the upper side, pale and glaucous on the lower, from an inch to an inch and a quarter long and from three-quarters of an inch to nearly an inch broad, with slender pale midribs, few obscure primary veins connected by conspicuously reticulate veinlets, and slender peduncles enlarged and clasping at the base and about an eighth of an inch long. The flowers, which appear as the leaves begin to unfold toward the end of April, are solitary or in pairs on slender nodding pedicels half an inch in length, their bracts being as long, or rather longer, than the calyx, which has a short nearly entire border; the corolla is white or pale straw-color, with a slightly gibbous tube gradually enlarged into the spreading reflexed acute lobes,

and about three-quarters of an inch long. The fruit ripens early in June, and is oblong, one-third of an inch long, light bright blue and suspended on slender nodding stems.

*Lonicera gracilipes* is occasionally found in American and European gardens under the name of *Lonicera* or *Zelostium Philomella*,

## Plant Notes.

**DIERVILLA JAPONICA.**—Many of the garden *Weigelas* bear abundant flowers of good color, ranging from a dark wine-color to pure white, but somehow the habit of these shrubs is stiff, and they do not seem to mingle well with other shrubs. In our last volume (see vol. ix., p. 405) we figured *Diervilla Japonica*, which was raised from seed gathered by Professor Sargent from wild plants in various parts of central and northern Japan. It is a common shrub by the banks of streams and along the borders of mountain woods. Here well-grown individual plants reach a height of fifteen feet and a diameter of from ten to twenty feet. This species is the only one which Professor Sargent saw, and he is inclined to believe that the three species of *Maximowicz* must be reduced to this one, which varies much in size in the pubescence of its leaves, in the number of its flowers and the length of the peduncles of its flower-clusters. It is from different types of this wild species, perhaps, that all the garden forms have been derived. It is easily propagated, and it has been flowering for three weeks past in the Arnold Arboretum and along the Boston parkways. Certainly it is a more graceful shrub than the *Weigelas* of gardens as we know them, and it can be unhesitatingly commended for park planting. The flower-clusters are sometimes long-stalked, and sometimes nearly sessile, and they are rose-colored, yellow, dark red or nearly white on the same plant, since the flowers which are very pale when they open turn darker as they fade.

## Cultural Department.

### Cultivation of the *Calochortus*.

**THE** various species of *Calochortus* have been coming into flower since early June, and now, at the end of the month, are in their best form. These native plants seem to be much neglected, though they are among the most distinctly and beautifully flowered of bulbs. It is probable that many who have ventured to grow them have been disappointed in results, for the cultural directions of catalogues are usually hazy or else incorrect. They also often recommend cultivation in frames, or other conditions which deter most growers from attempting their cultivation. My experience with all the species is that they are not tender nor at all difficult to flower in this latitude in an ordinary garden border. I have tested them for several years and sacrificed my first collection to satisfy myself as to what they would or would not survive. One should hesitate in offering any hard and fast rule for the cultivation of plants, for they can often be grown under widely differing conditions. *Calochortuses* grow naturally in regions rainless in summer, and where dormant plants waken into growth in the fall under the influence of moisture, but not necessarily of a high temperature. They are hardy here without protection, but must be classed with those bulbous plants whose foliage will not endure always the rigors of our winters. The successful growth of such bulbs requires that, after being thoroughly ripened in the early summer, they shall be kept perfectly dormant so late in the year that no foliage can appear above ground until early in the ensuing spring. The simplest and safest procedure is to lift the bulbs after the ripening foliage indicates dormancy and store them in dry earth in a warm dry place, and plant out when the ground has lost its warmth, which in this locality is in November. Under such treatment they grow and flower well here, even in soil too hard to work in dry weather, and with no other attention than that already suggested. Of course, one does not plant bulbs in manured soil or in soil rich in humus, which will hold water and ferment to their injury. In the state of nature many bulbs seek the depths evidently to escape detrimental surface humus, a desire to shun bad company, which is not always shared by human beings. *Calochortus* bulbs, if left in the ground here,

\* Miquel, *Versl. Med. Acad. Wetensch.*, ser. 2, ii., 85 (1863); *Procl. Fl. Jap.*, 158.—Franchet & Savatier, *Enum. Pl. Jap.*, i., 205.—Dippel, *Handb. Laubholz*, i., 257, f. 170 (a sterile shoot only).—Koehe, *Deutsche Dendr.*, 545.

may or may not survive the summer if the soil is not too wet, but the safe practice is to lift them.

There are more than a score of species. From a garden point of view they may be divided into two sections—the Star Tulips and the Mariposa, or Butterfly Tulips. The former are free-growing plants, many-stemmed and bear a profusion of small flowers, with petals closed into irregular globes. *Calochortus pulchellus* (yellow), *C. albus* and the red form, *C. amœna*, are the best trio. The Butterfly Tulips are entirely different in habit and form, and find their most distinct expression in the white and roseate flowered kinds, as these are spotted and lined with the butterfly markings, from which they receive the popular name. The markings are quaintly beautiful in dull reds, browns, yellows and green, sometimes in eye-like forms, at others in a few bold lines sketched, as it were, on some part of the broad petals, mostly on the base, but sometimes in the centre. Markings of similar character are also found on the very narrow green sepals. The flowers are three-petaled and about three inches in diameter, borne about twelve inches high on thin stems. The foliage is narrow and scanty. A good selection of these would be *C. venustus cœnatus*, *C. pictus*, *C. venustus roseus* and *C. Eldorado* (rose).

Of the yellow self-flowered kinds, perhaps, the best is *Calochortus luteus*, var. *concolor*, a deep golden flower and a vigorous species. There are also many purple forms, mostly self-colored or slightly shaded, which do not appeal to me as favorably as the others, though there are spotted kinds. The best is probably *C. splendens*, a lilac-colored form, which has finely dentated petals and the base of the cup filled with hair-like growths. Many of the *Calochortus* have these growths, but none, I think, in such profusion. Probably the specific name of this species refers rather to some one's botanical enthusiasm than the gratification of his color sense. *C. Catalinae* is a distinct kind, the white petals being flushed with purple on the outside. *Calochortus* seem to be attractive to a number of different insects, and they bear seeds freely. *C. Plumariæ* seems to be a late-flowering species.

J. N. Gerard.

### The Abelias.

THERE are some half a dozen species belonging to this genus, with one or two varieties, natives of northern India, Japan, China and Mexico, where one species grows at an elevation of 10,000 feet above the sea-level. *Abelia rupestris*, introduced by Robert Fortune from China nearly fifty years ago, is the species best known in this country, where it is frequently called *A. floribunda*, the name of a red-flowered species from Mexico. *A. rupestris* has flowers about an inch long, and white, the two lower divisions of the corolla being faintly tinged with pink. The calyx is of a brick-red color, and at certain times of the day the flowers are delicately scented. Although in this latitude *A. rupestris* will commence blooming by the latter part of June, it keeps on unfolding its flowers late into November. It would be hard to find a more desirable decorative shrub. It can be grown to form a perfect hedge or a compact specimen on the lawn when kept free from other things, or it may be had in long graceful branches by allowing the strong shoots to develop and by removing the twiggy growths at the base of the plant. For grouping in city parks and for cemetery use its long period of flowering should alone recommend it. The species is, without doubt, quite hardy in this vicinity, as plants which were put out by Downing are yet in a flourishing condition and promise to remain so for years to come. When we have the thermometer registering a few degrees below zero it is untouched, save in the shedding of its foliage, which in ordinary winters is evergreen. At Philadelphia I understand it stands out without protection, and at Mr. C. A. Dana's place, on the north shore of Long Island, it thrives with a little protection in winter. There is a variety of *A. rupestris* called *grandiflora* which has larger flowers but fewer of them.

The Mexican *Abelia floribunda* is at home on the peak of Orizaba, 10,000 feet above sea-level, and on the Cordilleras of Oaxaca. Although it has withstood several winters here it cannot be recommended for situations farther north, but for the southern states it ought to be an admirable plant. It has pendulous flowers about two inches long, rosy purple in color, and it blooms at an earlier period than *A. rupestris*; but there are enough scattering flowers all through the summer to make the plant attractive.

*Abelia triflora* is a native of the western Himalayas, where it flourishes at an altitude of 9,000 feet. It forms a very pretty little shrub with whitish yellow and pink flowers in clusters at the ends of the branches. It is quite hardy with us, and so are *A. serrata* and *A. uniflora*.

The most successful way of propagating these plants is by cuttings taken just after the wood is ripe in the fall. Flowering shoots with the ends cut off make good cuttings, which can be rooted in a cool frame or propagating-house.

Botanic Garden, Washington, D. C.

### Irises in Late June.

THE English Irises closely succeed the Spanish kinds and keep up a succession of attractive flowers. As is well known, these bulbous Irises are not English, but Pyrenean, and gained their name in Holland because they were introduced through the former country. The bulbs of this species are longer and rougher than those of the Spanish varieties. The leaves are wider and the flowers are larger in all their parts. They are white and all hues of purple from blue to red, and their effect is distinct from that of the brighter-colored Spanish Irises. The white-flowered form, known as *Mont Blanc*, is the choicest of this species, for it seems to be a true species. Shortly after the middle of July appear the Japanese Irises, as the hybrids of *I. lævigata*, or *Kämpferi*, have come to be known. The type of this species is a blue-purple, and, as is frequent in wild plants, a white-colored form. These Irises as imported have usually the same characteristics of flower and foliage, though the Japanese offer as a type form one with shorter and broader leaves. This may possibly be the form lately noticed in an importation and separated by Baker as *I. albo purpurea*. It is curious that though some fine forms of *I. lævigata* were sent here by Mr. Thomas Hogg soon after the Japanese treaty ports were opened many years ago, they did not meet with general appreciation until a few years ago. The type has evidently been broken for many years, and besides the typical forms there will now be found those with colorings through the entire gamut of purples from the blue to the dull-red end of that spectrum. They also appear in selfs and mixed colorings, the mixtures being in spots and reticulations usually. There are also single and double forms, which furnish altogether an extensive field for variation and a decided choice. As a rule, with their ordinarily sombre, dull colorings the thin large flowers, floating, as it were, and well raised on tall stems above the narrow foliage, are very effective in garden groups. Some of the forms, especially those which are double and splashed with varied colorings, do not seem to me great gains, and, like a good many other latter-day Japanese articles, seem to be produced to cater to the present department-store standard of taste. I notice that one of this type is frankly named in the catalogue, "Maple leaves spoiled by rain."

J. N. Gerard.

### Flower Garden Notes.

ALTHOUGH semi-tropical bedding plants are not making rapid growth, owing to continued cool nights, the weather in May and June suited most plants exactly. Perennials of all sorts have made remarkably vigorous growth, the frequent copious rainfalls during the past six weeks having been just what they needed. We have recently gone through our beds of herbaceous stock and securely staked all the plants which required it, and carefully hand-weeded the beds at the same time. Seed-pods of *Papaver orientale* have been cut off, and of a few other plants which become nuisances if allowed to seed without restraint, and bare spaces of ground have been lightly stirred with a hoe. Now that warm and dry weather is setting in, the advantages of leaving on the old manure which covered the beds during early winter and of not wheeling it away or digging it into the ground are apparent; beds with a mulching of this sort can stand quite a severe drought without suffering. Perennial borders usually have a somewhat seared and dilapidated appearance after the middle of July, when *Pæonias*, Irises and many other showy flowers have waned, but *Zinnias*, *Dianthus*, *Gaillardias* and numerous other bright annuals among these plants make the beds a mass of color from the latter part of May until they are cut down by frost.

Seeds of such biennials as Sweet William, Canterbury Bells, *Antirrhinums*, Wallflowers, etc., have been recently sown, and will be kept well watered until they germinate. When large enough to handle, these are pricked off in nursery rows a foot apart. *Coreopsis grandiflora* is one of the best hardy plants grown for cut flowers, and a sowing of it may be made now to advantage. We lift and pot a number of these plants late in the fall and force them into bloom by the middle of May; they are particularly acceptable on Memorial Day, when bright yellow flowers are rather scarce. Pansies we sow early in August, and find *Trimardeau* the best all-round variety. This season

has suited Pansies better than any I can recall. Hollyhocks should have been sown before this time, but it is not too late to do so now.

Beds of tender-flowering and foliage plants require some attention each week to keep them attractive. Seed-pods and decaying foliage from Cannas, faded flower-trusses from Geraniums and the tops of many foliage plants should be removed, while the surface soil should be kept stirred and all grass verges trimmed. No flower-bed can look well if the verges are poorly kept, but this neglect is often noticed in private and public grounds. Cannas, to be at their best, should have copious waterings in dry weather, as they are semi-aquatic, and a scattering of fertilizer over the beds occasionally will help in the development of superior flower-spikes. The new Italian varieties, Austria and Italia, are very robust growers and flower freely, but the flowers are rather flimsy. Burbank appears to belong to the same class; it is, however, a grand yellow flower.

Hardy Roses of all sorts have produced capital flowers this year, the cool, showery weather bringing them on finely. Many of the old hybrid Perpetuals raised a generation or two ago still lead as the most popular and profitable sorts. Some varieties of more recent introduction are, however, great acquisitions; specially good are Clio, Marchioness of Londonderry, Captain Hayward, Earl of Dufferin, Margaret Dickson, Mrs. Paul and Helen Keller, all of which are reliably hardy here and possessed of good constitutions. The flowering season is now nearly past, and all faded blooms should be removed; also any Manetti or Brier shoots, which rob the plants of much vitality if allowed to remain. Crimson Rambler, one of the most charming pillar Roses ever introduced, is now a mass of bloom. If the new French varieties, Thalia, Aglaia and Euphrosyne, which we are trying, prove hardy and equally satisfactory as white, yellow and pink varieties, they are bound to become extremely popular. Mr. W. A. Manda, who has already sent out some pretty Wichuraiana hybrids, recently exhibited in Boston some crosses between Rosa Wichuraiana and Madame Hoste and Perle des Jardins which were deemed worthy of first-class certificates. Mr. Manda says these crosses are thoroughly hardy, make rampant growth and are very floriferous.

Carnations grown expressly for summer blooming are now beginning to flower freely and have recently been staked up. The winter-blooming stock must be looked over weekly and necessary topping done, the ground kept well stirred and all weeds growing near the plants carefully pulled up by hand. Violets look remarkably well thus far and are now commencing to make runners, which should be removed once in two or three weeks. Our last sowing of Asters and Stocks was made toward the end of June. The plants of the first sowing of Asters, Queen of the Earlies, are now well branched and will soon furnish flowers for cutting. Gladioli we plant in several batches for a succession of cut flowers. The last lot has just been put out, and these are useful during September and early October. If Sweet Peas have not already been mulched some suitable covering should be given them; seaweed, grass or short spent manure answer equally well. It should be remembered that they love to be moist at the root, and that to prolong the flowering season none of the flowers should be allowed to go to seed.

## Correspondence.

### Licorice Root.

To the Editor of GARDEN AND FOREST:

Sir,—Your brief allusion to licorice root on page 253 hardly indicates the magnitude of the trade in this commodity. It really comes to this country in cargo lots, and you may be interested in a few facts well known to the trade and which have been published at different times in various pharmaceutical journals.

Until less than thirty years ago Spain was the main source of supply for this country. Persistent collecting has almost exterminated it in some sections of that country and much of the limited quantity now exported is of small and fibrous roots skillfully assorted and packed with the few larger ones to make the best effect. The Spanish licorice is sweeter than any other, and is specially valued for use in lozenges and pharmaceutical preparations. The extract of the root boiled down and evaporated is familiar to us in rolls an inch or more in diameter and about eight inches long. A test of purity in this form is its solubility in water, but adulteration is common. Potato starch and other farinaceous substances are used, with sugar, in licorice confectionery. The root from Sicily ap-

proaches that from Spain in its mild and sweet qualities, and the Italian roots yield the richest extract.

Immense tracts in Russia and Asia Minor are covered with the Licorice-plant, which is regarded by farmers as a nuisance to be cleared away before the ground can be used for agriculture. The trade in licorice began in Russia about twenty years ago, and the plains of that country offer an almost unlimited field for collectors. The Caucasus Mountains are also a favorite collecting ground, and uncultivated districts in Turkey and Greece, for all the licorice of commerce grows wild. Greek root is a name popularly given in the trade to all licorice root except the Spanish. The saccharine and starchy properties are affected by the soil, and also the color of the root, which is yellowish, reddish or brown. The tap-roots of one kind of Licorice extend three to six inches downward, and of another sort to but half that depth, the latter being, of course, more easily gathered. The digging begins in autumn after the rains have set in, and the same ground yields a crop once in three years. In Russia, now the principal exporting country, the collecting is done by natives of the peasant class in the section between the Black and the Caspian Seas. The roots are delivered at local stations, cleaned, some of them peeled, dried, packed and carried by rail to the seacoast. Large factories for curing the green roots and for extracting the juice are operated in Transcaucasia by English capitalists, and the largest of these each have a yearly output of 5,000 tons, or above 10,000,000 pounds. So heavy is the trade that a fleet of vessels is employed on the Black and Caspian Seas in transporting licorice alone.

The Russian roots and those from all that part of Europe and from Asia Minor have a slight acidity, and are used mainly for flavoring tobacco and various drinks. The price of these is considerably less than that for Spanish roots, and mature first-grade roots from Spain command twice as much. Like Ginseng, this root is highly esteemed by the Chinese, and is largely used by them as a tonic and for supposed nutritive qualities. In 1892 the United States alone imported one hundred million pounds of licorice, and the quantity is steadily increasing.

Philadelphia, Pa.

B.

### The Bladder Nuts.

To the Editor of GARDEN AND FOREST:

Sir,—I am surprised that the European *Staphylea pinnata* is not more often found in our shrubberies. It is a good deal better than *S. trifolia*, the native Bladder Nut of our eastern states with clusters of white bell-shaped flowers. *S. pinnata* has bolder leaves, larger flowers, which are pure white and fragrant. *S. Bumalda*, from Japan, is also very interesting, and *S. Colchica*, whose flowers have the fragrance of Orange blossoms, is the most beautiful of all, a compact little shrub, which is said to be good for forcing. All these plants are interesting, even after the flowers are gone, with their inflated pods which give them the common name. Few shrubs have given me more pleasure than the various species of this genus.

Shepherdstown, W. Va.

Danske Dandridge.

### Periodical Literature.

A recent article in the *Pall Mall Gazette* gives an interesting account of the culture and brief harvest of those strange little "immortal" flowers so closely associated with mortality on the Continent and in London also, though the fashion for them in England is of a more recent date. Naturally they are a valuable crop, and, strangely enough, a somewhat difficult one to handle, as they will not grow everywhere. The world's supply of them comes from the neighborhood of a little burg, Ollioules, in the Var, near Toulon, half a dozen miles out on the main road to Marseilles, in the south of France. There, on the edge of a straight and narrow pass, bordered with piled up, cleft and calcined rocks, on the arid soil that suits it best, grows the "Immortelle," that curious *Amaranth*, *Helichrysum orientale*. The plants are low, flat and rosette-like, appressed on the ground, each one sending up two or three slender stalks, which about the first week in June are covered with small Primrose-buds. Each stalk carries some twenty or thirty buds, and the right moment for their gathering must be carefully watched for by the harvester, as too early is as disastrous as too late, since the flower then perishes in drying. After the drying process, an easy

one in the sun-baked valley, comes the dyeing, when the "immortelle" takes on its conventional ruddy color. Many of them are also dyed black for the purpose of picking out the legend or dedication on cross or wreath. They are then bunched and boxed for transportation to Paris or London, as the case may be. The crosses and wreaths are largely made up on the spot, the feminine fingers at Ollioules being passing deft at this unique and intricate industry. Every bud has to be sewed into its place on the framework of plaited straw, which is the backbone of the design and which must not show when the article is ready for the market.

"Immortelle" prices vary at Ollioules; last year, for instance, they sold for £3 per hundredweight, and a good year brings in £8,000 to the small community.

### Recent Publications.

#### The Spruce Forests of Maine.—II.

*Third Annual Report of the Forest Commissioner of the State of Maine, 1896.* Augusta: Burleigh & Flint.

This rapidly diminishing supply of standing timber makes the question of the future growth of the trees which remain and the reproduction of new ones one of vital moment, and Mr. Cary gives much space and many valuable data to its discussion. He ascertains the rate of growth that is to be expected of the trees which the lumberman has left, and argues the question whether and to what extent more economical cutting pays. At present the practice, varying in different parts according to the facilities of bringing material to market, is to cut down to eight-inch diameter, breast-high, although occasionally larger trees are left uncut, being either overlooked or inconvenient to get out. The amount of wood left to the acre of measurable volume of Spruce Mr. Cary sets down as in general varying from 300 to 500 cubic feet, according to the closer or more liberal practice of the logger. On these left-over trees Mr. Cary determines the annual growth in volume a year at from two to three per cent. compound interest. The method employed to arrive at such result, namely, by the use of Pressler's accretion borer, is, to be sure, of questionable value for the purpose for which Mr. Cary uses it, although excellent under very different conditions; nevertheless, for a general statement, where accuracy is not of importance, we may accept the results as sufficiently close. If we take the largest figure of tree volume remaining, namely 500 cubic feet, at two per cent., the annual growth is ten cubic feet "which," Mr. Cary says, "at a fair equivalent might be called forty board feet." Eventually such a translation into board feet may become permissible, but it is hardly so for the first ten to twenty years, considering that we have to deal with only small-sized timber. Nevertheless, if we allow this figure to prevail over the entire area in question, and assume that the uncut portions participate in the same proportion of increase, the 2,800 square miles involved would add annually a round seventy million feet, board measure.

Mr. Cary, himself, guesses—for there is after all but little more than a guess possible from the meagre data—that the Kennebec area produces fifty-three million feet new growth annually. Applying the same ratio to the much harder cut, and hence, in regard to annual growth, much less favorably situated Androscoggin district, we arrive at the same total, namely, seventy million feet of new growth on these two areas. That is to say, after the sixteen years, for which the virgin supplies are estimated to last, there would have accumulated in new growth at best not enough to supply four years of the present annual cut. Mr. Cary abstains from applying his figures or drawing conclusions in this way; on the contrary, he speaks with a sanguine air of "the bounty of nature in setting at our hand greater supplies, when all are considered, than we are yet able to utilize," and thinks that "to talk of European economy for the state of Maine is folly."

Many other notes of interest are to be found in the vol-

ume, which the interested reader will find hidden away in the recesses of this woodman's tale, of which we can mention only a few. Here is, for instance, a most valuable observation to be heeded by the forest exploiter, namely, that where Spruce forms the prominent feature of the virgin growth, the culling process of the lumberman prepares a large loss in the shape of windfalls; older trees left, having lost the support of their neighbors, are uprooted and thrown. This loss Mr. Cary estimates as often more than half the timber left. Thus he states the account of a sample acre as follows:

Left standing by the logger,	-	850	cubic feet.
Blown down in 17 years,	-	500	" "
Remainder,	-	350	" "
Growth on it during 17 years,	-	150	" "
Now standing,	-	500	" "
Balance lost,	-	350	" "

The loss is really much greater, almost double; for we are entitled to the accretion on the entire amount left standing, hence adding to the 850 cubic feet, which the logger left, at the assumed rate of increase (2½ per cent.) for seventeen years, that is, 340 cubic feet, and deducting the amount now standing, namely, 500 feet, we find that 690 feet at least were lost during the time in original growth and accretion.

The account with another acre is calculated as follows:

Original stand,	52 trees of 12-inch and over,	1,360	cubic feet.
214	" of 3-12 inch,	- - -	1,440 " "
266	"	- - -	2,800 " "
Utilized 36 per cent.	in logs hauled,	- - -	1,020 " "
	(in stumps and tops,	- - -	340 " "
Wasted 47 per cent.	destroyed in cutting,	- - -	480 " "
	blown down,	- - -	480 " "
Left to grow, 17 per cent.,	- - - - -	- - -	480 " "
		- - -	2,800 " "

Mr. Cary advises, therefore, to cut down to the lowest available diameter wherever Spruce stands thickly, in order to reduce the inevitable loss by windfall, while in mixed growths in which hardwoods predominate, and hence the timber left is supported by neighbors, the cut may be more conservative without danger of windfall.

He then attempts, with admittedly insufficient data, to discuss the financial difference of a severe and a conservative cut. The results can hardly be more than illustrative of what natural reasoning leads to, namely, that the severer the cut the less is left to grow and the longer the time, when the logger may come again on his robbing expedition.

In this part of the discussion Mr. Cary makes what, from the forestry point of view, we must consider a vital omission when he leaves the question of reproduction entirely undiscussed. This is like a stockman who sees in his swine, young and old, nothing but animals to be fattened and slaughtered as soon as they are fit to kill, but provides for no new litters to replenish the herd and keep up the supply. The young growth left is to grow on to log size and then to be cut—that is to say, the robbing system is simply to be continued as long as there is something to rob. It would have been proper for Mr. Cary to point out that under the present system, while the hardwoods remain occupants of the ground, with the Spruce constantly diminishing in number, not only will the rate of growth on the smaller sizes be constantly diminished by reason of the shade of the overgrowing hardwoods, but it is only a question of time, and not a very long time, when the Spruce will be practically eradicated, at least in all mixed growths. He fails to point out to the lumbermen, for whose benefit he attempts to find the best method of management, that this system of culling out the Spruce must inevitably result in killing out all Spruce growth.

With all its shortcomings and its faults from a literary point of view, which seem due to the pardonably exuberant enthusiasm of a man who has found a new and promising field of work, the study of this report cannot but be helpful to all who are interested in practical forestry prob-

lems. The author states modestly enough that when he took the field he had "very indefinite ideas" as to the object to be attained, and began "with partially unformed purposes." This may account largely for the lack of form in the results. The author is a thorough woodman and good observer, and his contributions to practical forestry will, no doubt, gain in value with experience.

Washington, D. C.

B. E. Fernow.

### Notes.

The degree of Master of Arts has been conferred by Harvard University upon Mr. C. E. Faxon for his attainments in science and art. The readers of GARDEN AND FOREST know something of the substantial quality of his botanical knowledge and of his skill as a botanical draughtsman.

A very striking display was made at Floral Park during the last week in June when four acres of Japanese Irises were in flower. Nearly one acre is devoted to a pure white sort named Gold Bound, while the dark purple kinds are best represented by the variety Mahogany. The pale mauve of Exquisite and the bright blue of Blue Jay indicate some of the colors through which these flowers range. Individual flowers are said to measure nearly ten inches in diameter and single plants carry from twenty to twenty-five spikes.

A correspondent of *The Gardeners' Chronicle* writes from Manilla of a remarkable *Dendrobium*, a new species which has been named *Victoriæ reginæ*, in commemoration of the Queen's jubilee. The plant grows at an altitude of 6,000 feet and higher, and the branching stems produce great numbers of richly dark blue and white blossoms borne in trusses and lasting for several weeks. The flowers are more than an inch in diameter, the petals at the base being white, with a large blue blotch at the edges, the lip ovate, oblong and of the same color. It is, without doubt, one of the most striking of the *Dendrobiums*.

Professor Bailey and Mr. Wilhelm Miller have issued another bulletin on the *Chrysanthemum* which contains much that is of interest to florists and flower lovers generally. Mr. Miller's chapter entitled "*Chrysanthemums at Home*" is certainly worth publishing under the Nixon Act, and perhaps the horticultural knowledge which can be disseminated by investigations and publications of this character justify the use of the costly machinery of the experiment station in this particular direction. The question is whether it could not be used to better advantage elsewhere. But since the bulletin is published primarily for educational purposes, we must express our regret at the use of such a barbarism as "mum" for *Chrysanthemum*. A subject which is of sufficient importance to be discussed in a bulletin from a university ought to command the use of dignified and scholarly language.

What is said to be the largest sale of Mediterranean fruit ever made in this country took place in this city on Monday of last week, when the cargoes of three steamers were disposed of. Almost 45,000 packages of oranges and lemons were bid off in the auction, which lasted five and three-quarter hours. The sales aggregated almost \$75,000, or \$200 for each minute of that time. When it is considered that the report of an expected cold wave influenced the demand for lemons unfavorably, and that the sales were in as small lots as five boxes and upward, the sustained energy of the auctioneer and the general business dispatch are better realized. A cargo of the same fruits was disposed of on each succeeding day of last week, and the week's sales amounted to 30,300 boxes of Sorrento, Palermo, Messina, Rodi and Catania oranges and 122,050 boxes of Messina, Palermo, Maiori and Sorrento lemons.

The United States Department of Agriculture has just issued the first number of a new series of brief popular bulletins based upon the work of the experiment stations for the purpose of setting forth the practical side of certain features in the progress of agricultural investigation. An introductory note states that this work must not be depended upon to lay down any "rules for farming," and that the results reported are generally regarded as tentative and suggestive rather than conclusive, leaving to the individual farmer the problem of applying the results of experiments to his own peculiar conditions. This bulletin of thirty pages treats of a dozen topics, and every paragraph is full of instruction. A chapter of three pages devoted to the subject of barnyard-manure is exceptionally good in its treatment of a subject of prime practical importance and one that has been the study of the most eminent agricultural chemists ever since agricultural chemistry has

been a science. How to manage and preserve this product in an economical way without losing any of its fertilizing value is a problem in which every cultivator of the soil is vitally interested, and in these few paragraphs some of the results of the latest researches of the leading experimenters in the country are explained in clear and simple language.

*The Rural New Yorker* regrets that *Magnolia hypoleuca* is still a rare tree in the United States, and, indeed, it is remarkable that so beautiful a tree remains comparatively unknown, although it was sent to the United States thirty-two years ago from Japan by Thomas Hogg. We published a figure of it in the first volume of GARDEN AND FOREST, taken from a tree which was planted with many other rare Japanese plants at the foot of Eighty-fourth Street, in this city, in 1865, where it may still be standing, although an alteration in the grade of the street has left it bruised and hidden behind a bank of earth. The foliage is light bright green above and pale steel-blue or almost silvery beneath, and its large flowers exhale an odor which by some is thought to resemble that of a pineapple, while others describe it as a combination of the wintergreen and the fruit of the banana. They have cream-white petals and scarlet filaments, and are six or seven inches across when fully expanded. In this city these flowers appear early in June, after the tree is in full leaf. It is a common forest-tree in the northern island of Japan, where it attains a height of a hundred feet or more with a trunk diameter of nearly two feet.

Bartlett, Lawson, Beurre Gifford, Comet, Wilder and Lawrence pears were among the fruits in sixty-one car-loads received here from California last week, with Alexander apples, and peaches, plums, prunes and cherries in extended variety. It is interesting to note the trade in dried fruits so late in the season, and evaporated apples, raspberries, huckleberries, blackberries, cherries, apricots, peaches and plums of last year's crop are sold in the home markets and exported in considerable quantities. The highest grade of evaporated apples are still in demand for shipment abroad, and nearly 1,700 boxes of dried fruits and raisins left this port for Liverpool alone last week, while 850 packages of dried California fruits were shipped to Hamburg. So late as June 19th the weekly output of dried prunes from San José, California, amounted to above 45,000 pounds. Other exports of fruits and vegetables which suggest the complex demands of trade are 900 crates of bananas shipped to England during the past fortnight, and 245 barrels of winter apples. Several thousand barrels of American potatoes leave this port for Cuba each week at this season, and the first consignment for this year of fresh California fruits, consisting of five car-loads, was started from that state for London on June 29th and is due in England about July 13th.

A bulletin just issued by the Agricultural Experiment Station at Alabama gives an account of some hybrids between American and foreign Cotton-plants which were tested last year. Seeds of foreign varieties which had been acclimated by planting in the United States, from different parts of India and from Egypt, were crossed both with the Long Staple and Short Staple varieties grown in the United States. Sea Island Cotton, which belongs to the species *Gossypium maritimum*, sells for twelve cents a pound, but the demand is greater than the supply, and therefore the Long Staple Cottons of Egypt find ready market here. Fifty thousand bales of this cotton were sold in the United States in 1896, and buyers were glad to pay eleven cents a pound for it. Without giving in detail the results of hybridization, it may be said that many of the Indian Cottons, as, for example, those derived from *G. hirsutum*, did not blend with certain American kinds, but some of the Egyptian forms which are varieties of *G. maritimum*, to which our Sea Island Cotton is referred, combine well with this type. Mr. Mell, the experimenter, concludes that the hybrids between the Egyptian and American kinds are generally equal to the parents in good qualities, and the Egyptian kinds make better fibre in length of strand, in strength and texture, than the Indian kinds. The Sea Island Cotton in combination with two of the Egyptian varieties produces a superior grade of staple, and the plant is rather prolific, so that there seems to be a prospect of securing a variety which will be a healthy, long-staple, upland cotton. A blending of small-bolled species with large-bolled species is not advised, since the resulting cross is generally weak, but when plants referred to *G. maritimum*, which is slow in maturing its bolls, so that frost often catches them before they are open, are united with a suitable strain of *G. hirsutum*, the hybrid reaches maturity quicker and is more prolific, and the combination of these species yields a plant which produces fibre of the best grade in strength, maturity, twist, length, fineness and yield to the acre.

## One Way to Reduce the Cost of Park Maintenance.

THERE are few public parks in this country in which the trained eye does not generally detect a disheveled or untidy look. The shrubberies are disfigured by dead wood; strong, coarse-growing bushes are smothering the more delicate ones; trees are defoliated by insects and fungi, and many of them are making a sickly growth; the road borders are ragged and the general effect is a weak imitation of untamed nature. The hand of man is visible everywhere, but his efforts are too feeble to be the controlling force, and they rather mar than make the landscape. If this fact is pointed out to park superintendents or park commissioners they at once reply that in the first place they cannot secure enough money to do the work as it is done in the most carefully managed private grounds, while, in the second place, if they had all the money the work demands it would be impossible to secure enough skilled labor and intelligent superintendence to do it in the most approved way. And there is much to justify this excuse—that is, parks do languish for lack of maintenance, and adequate maintenance is impracticable for lack of funds and trained workmen.

Under such conditions the parks must suffer, of course, but it is singular that some commissioner, instead of struggling after appropriations which, under the growing expenses of modern cities, are much harder to secure every year, does not argue in favor of designing and constructing parks in such a way that they can be cared for more cheaply. We are speaking now of large rural parks where quiet landscapes are the essential features. To provide such landscapes we need good grass, good trees, an abundance of hardy shrubs effectively arranged, with good roads and walks to make the pleasant prospects available. Little else is necessary, from an artistic point of view, for the more simple the material the more effective and enduring will be the picture which an artist of real creative faculty will produce. To insure cheap maintenance it is essential that all work should, in the first place, be done thoroughly and well. The roads should be perfectly drained and constructed of the best material, and there should not be too many of them. Equally or even more

important is it to have a deep, rich, well-drained soil, for turf on such a soil lasts longer and is more easily kept free from weeds, while the trees and shrubs planted in it will also be long-lived and their branches will not be dying back every year as they do on trees and shrubs which lead a starved life on thin, sterile soil. Of course, the hardiest trees and shrubs should be selected, for there is no economy in planting trees or shrubs which are liable to be killed every year or so, partially if not entirely, by frost or heat, or drought or winds, or some other freak of American weather which annually works ruin upon a large percentage of our exotic garden plants. Nor should we select plants like garden Roses, which, unless carefully watched, are disfigured every year by insects. It costs time and labor to cut out dead or dying branches, to remove dead trees and fight insects.

But the shrubs and trees which need the least attention are not only the most economical ones to plant; they are the best from an artistic point of view. The fact is, that for producing large effects, for making scenes which a painter would like to transfer to canvas, we do not need any great variety. With wood borders of our native American trees, a dozen good shrubs, half as many climbers and green turf, a good landscape-gardener can produce scenery which is more truly restful to nerves overstrained by city life than any more elaborate planting scheme could make. In fact, it is quite impossible to take all the showy trees and shrubs which are available in this climate and group them together so that they will have any consistency or unity of design. A landscape-painter would make himself ridiculous if he argued that his picture was valuable in proportion to the number of different colors which he could manage to work into his canvas, and certainly the landscape-gardener who tries to use all known shrubs and trees of diverse form and habit, and with flowers and leaves of every color, is more likely to create a landscape which resembles a crazy quilt than one which suggests a picture of peace. Some of the noblest pleasure-grounds in the world contain nothing but big trees and grass; and how superior simplicity of this sort is to the fussiness of modern decorative gardening will be appreciated by any one who compares St. James Park, in London, with Battersea, on the other side of the Thames.

The tendency among superintendents of planting in parks is constantly toward showy plants, and particularly exotic ones, and if they are rather rare so much the better. They seem to feel that the way to establish a reputation is to produce something that will excite surprise and which will strike the beholder as remarkable, and, no doubt, the shrubs and trees which can show the gayest flowers will be more likely to arrest popular attention, and therefore these plants are very largely selected. Now, a very elaborate and varied planting scheme may be admissible on private grounds of limited extent, although on a large place a true artist will exercise restraint in this particular. But when a man can afford to plant a collection of rarities he can probably afford to maintain them. If any of them are unable to take care of themselves he pays for the labor and other expenses which are required to give them special protection. He sprays them against attacks of fungous diseases and defends them against the assaults of destructive insects; when they die back in winter, his gardeners cut the dead wood away and he gives them all the pruning and training that is necessary to keep them looking trim and happy. Public grounds, however, should be considered from an entirely different point of view. Shrubs with gaudy flowers are out of place where children, old or young, will be tempted to break off their branches. Shrubs and trees which need constant pruning to keep them from looking shabby should be rejected. Elaboration in planting ought to be forbidden as utterly as needless construction. The very qualities which would make a particular shrub or tree tempting to a man who is searching for a showy specimen to decorate the border of his small lawn are the very ones which ought to condemn it for use

in a park where the general effect is the first thing aimed at and where economy in maintenance is a necessity.

The sum of the matter is that one good way to reduce the cost of maintaining rural parks is to make them less pretentious and artificial in design and to construct them in the outset in the most thorough manner. This will not only save money, but it will lessen the danger of sins against good taste. At least, it will tend to encourage that simplicity which is the foundation quality of all sincere art.

### Second-growth White Pine in Pennsylvania.

THE valley along Hickory Creek and its tributaries—Beaver, Otter and Queen Creeks—the slopes and the tops of the hills which surround it, extending to the banks of Tionesta Creek, are in places abundantly covered with thrifty young White Pines. The second-growth White Pine here is of particular value; it affords an opportunity to study the process of natural regeneration of White Pine and its progressive development under conditions almost like those which would generally take place in the pineries, should the cuttings be regulated so as to assure the complete reproduction of the Pine. While the White Pine in Pennsylvania reproduces itself readily everywhere—in the openings of the forest, on the cut-over lands and on the abandoned fields—still the areas of second-growth White Pine are usually small, and the park-like aspect of the young growth does not allow us to draw conclusions as to what an area completely restocked would look like, and as to what the progressive development of a second-growth White Pine would be under forest conditions. The unsatisfactory state of reproduction of White Pine is due mainly to the lack of a sufficient quantity of good seeds. The only seeding trees to be found on the cut-over lands are the few defective Pines left, which provide undesirable seeds with a very low percentage of germination. Then also the inferior hardwoods, always spared by the axe, cover the ground with a thick young growth which hinders considerably the germination and development of the few Pine seeds accidentally brought by wind. The successful and complete regeneration of the Pine at Hickory Valley finds its explanation in the fact that the areas now grown up with young Pine, when stripped over forty years ago of their original growth, were surrounded by forest, and thus abundantly provided with seeds from the adjoining walls of standing White Pine.

An acre representing typical conditions of regeneration in the valley was staked off on a steep slope facing the south-west. The young Pine on the acre was mixed with hardwoods and scattering Hemlock. The dense undergrowth consisted of 160 Beech-trees, 108 Maples, 12 Oaks, 9 Ashes, 76 Black Birches, 189 Yellow Birches, 100 Ironwoods, 2 Black Cherry trees, 2 Hickories and 248 Hemlocks, all of which were very small, less than three inches in diameter and from five to ten feet high. The soil, being here uniform, was a clayey loam intermixed with shale, yellowish brown in color, deep, fresh, drained on the south by Beaver and on the west by Hickory Creek, with three or four inches of mold on top and a surface cover of abundant leaves and a few Ferns. The subsoil was a laminated shale of an indefinite depth. The age of the Pines ranged from forty-two to forty-eight years. The canopy formed by the Pine in places represented a full cover, but the average density of crown cover on the acre was 0.8. Of the 753 trees on the acre there were 383 White Pines, 50 Beeches, 46 Maples, 20 Oaks, 16 Ashes, 73 Black Birches, 59 Yellow Birches, 13 Ironwoods, 15 Black Cherries and a few Aspens and Butternuts not counted.

The following are the dimensions of the White Pine: One tree was fifteen inches in diameter, breast-high; one, fourteen inches; one, thirteen inches; four were twelve inches; twelve, eleven inches; twenty-one, ten inches; twenty-eight, nine inches; twenty-four, eight inches; twenty-three, seven inches; thirty-four, six inches; forty-nine, five

inches; forty-one, four inches; fifty-six, three inches, and eighty-eight were under three inches in diameter. The number of Pines over three inches in diameter is thus 295, while only 149 were more than six inches in diameter.

The dimensions of the species intermixed are as follows: Seven Hemlocks, at breast-high, ranged from six inches to twenty-four inches in diameter, and seventy-one from three to six inches. Two Beeches ranged from six to fourteen inches, and forty-eight from three to six inches. Two Maples ranged from six to ten inches, and forty-four from three to six inches. Seven Oaks ranged from six to ten inches, and thirteen from three to six inches. Four Ashes ranged from six to ten inches, and twelve from three to six inches. Seventy-three Black Birches ranged from three to six inches; two Yellow Birches from six to ten inches, and fifty-seven from three to six inches. One Ironwood ranged from ten to fourteen inches, and twelve from three to six inches. Five Black Cherries ranged from six to ten inches, and ten from three to six inches.

From these measurements it is seen that while the number of White Pines over three inches in diameter constitutes only forty-four per cent. of the total number of trees on the acre, the number of White Pines over six inches in diameter, when compared with that of all the other species on the acre above that dimension, swells to the dominating per cent. of eighty-three. It is not astonishing, then, that the reproduced areas at Hickory Valley carry with them an impression of being stocked exclusively with White Pines. The close examination of the above tables throws a good deal of light upon the nature and process of regeneration of White Pine. The total number of trees on the acre, including the undergrowth, is 1,723; the number of White Pines is only 383. The Pines then have started and grown among the hardwoods, which, being large in number, did not, however, interfere either with the reproductive power or the thriftiness of the Pines. The hardwoods were gradually crowded out, and in the long and natural struggle for light and room succeeded only so far as to retain twenty-three individuals of considerable size, leaving all the others, together with the Hemlock, far below the canopy formed by vigorous Pines. This clearly shows that, with the provision of a sufficient quantity of Pine-seeds, the hardwoods need not interfere with the successful reproduction of White Pine, unless it be old and dense timber which shades the ground and young growth unduly. On the contrary, the hardwoods, instead of being undesirable weeds, may render to the success of regeneration of White Pine manifold and valuable services. First of all, the hardwoods on the ground prevent it from growing up into weeds, which are far more dangerous to the starting Pines than the hardwoods. In the seedling stage the Pines are protected by the hardwoods from frost, which, when occurring at the beginning either of spring or fall, is liable to kill the terminal branches of the Pines. When the Pines reach a similar height with the hardwoods, the latter become stimulants for the height-growth of the Pines. When the Pines have lifted their boles above those of the hardwoods, the latter assume the role of undergrowth, protecting on one hand the ground from the direct rays of the sun, and on the other providing ample shade for the shafts of the Pines, and thus clearing them of limbs. The accumulating leaves of the hardwoods shed annually form a rich litter, a natural forest-manure, which improves the physical conditions of the soil, thus indirectly benefiting the growth of the Pines. Then the larger number of trees to the acre usually found in mixed forests affords ample protection from wind. Adding to all this, that the spread of diseases caused either by fungi or insects is naturally prevented in mixed forests, the value of the hardwoods with regard to the regeneration of White Pine and its development may be better understood.

The thrifty appearance of the White Pines at the valley, the straightness and clearness of their shafts and the proportionally developed crowns prove that the Pines here

were considerably benefited in their growth by the presence of the hardwoods.

For the information of the Division of Forestry twenty-seven individual Pines from this locality were measured and completely analyzed. The table given below illustrates the progressive development of the dominant young White Pines at Hickory valley :

TABLE SHOWING THE RATE OF GROWTH OF DOMINANT YOUNG WHITE PINES AT HICKORY VALLEY, PENNSYLVANIA.

Age.	Diameter, breast-high, without bark.	Height of tree.	Volume without bark.	Periodical accretion.				Average annual accretion.	Current annual accretion.
				Decade.	Height.	Diameter.	Volume.		
	Inches.	Feet.	Cu. ft.		Feet.	Inches.	Cu. ft.	Cu. ft.	Cu. ft.
10	3.4	9	0.3	1	9	3.4	0.3	0.03	0.03
20	7.2	26	3.3	2	17	3.8	3.0	0.16	0.30
30	9.5	42	9.2	3	16	2.3	5.9	0.31	0.59
40	12.2	54	19.7	4	12	2.7	10.5	0.49	1.05

The height of the Pines on the sample acre was from fifty-five to sixty-five feet, with a volume of stems varying from sixteen to thirty cubic feet. The yield of the acre for the Pine only, not considering the 144 Pines under four inches in diameter, was 1,824 cubic feet, which means an average annual accretion of forty cubic feet. The current annual accretion during the last ten years was 110 feet. It will certainly increase up to eighty years, but assuming that, contrary to biological laws, the current accretion will remain the same up to one hundred years, the yield of the acre for that age will be at least 8,000 cubic feet. Making an allowance of fifty per cent. or sixty per cent. of waste when passing through the mill, the 8,000 cubic feet will furnish from forty to fifty thousand feet, board measure. A sum of from \$200 to \$250 net could then be realized after the lapse of fifty-five years.\* A calculation with four per cent. compound interest establishes the present value of the acre at from \$23.00 to \$29.00 when kept under forest growth. For agricultural purposes it is not worth anything, because the steep slopes of the hills from 400 to 500 feet above any roadway are absolutely unfit for cultivation.

Washington, D. C.

A. K. Mlodziansky.

### Roots in Commerce.—II.

THE Butterfly-weed, *Asclepias tuberosa*, of our roadsides and dry pastures, with its well-known deep orange-colored flowers, is represented in trade by its root, which is known as Pleurisy-root. Growing throughout the United States, this plant is particularly abundant in the south, where the fleshy, irregular, often spindle-shaped roots are esteemed as a remedy for flatulence and indigestion as well as for pleurisy and affection of the lungs. This Milkweed differs from other species of *Asclepias* in not giving out a milky juice when cut or bruised. Another root of the Milkweed family in commerce is Indian Hemp, *Apocynum cannabinum*, used as an emetic and cathartic. The small shrub *Spiræa Ulmaria* affords the root which appears in the lists as Queen of the Meadow, and is known also as Meadow-sweet or Meadowwort. This part of the plant is considered less valuable, however, than the leaves and bark. Pellitory, the root of the composite plant, *Anacylus Pyrethrum*, brought from the Mediterranean regions of Africa and Europe, is especially useful in dentistry as a powerful irritant and sialogogue. At one time Arrowroot, *Maranta arundinacea*, was successfully grown in Georgia and Florida, but the supplies for this country now come almost entirely from Bermuda by way of England, and from St. Vincent, one of the British West India islands. It is also cultivated in other of the West Indies, and in the East Indies and Africa. Arrowroot from the Bermudas has the highest reputation, and its cultivation and manufacture are carried on in primitive fashion by the

\* To be sure, the future generation will be glad to pay \$5.00 per thousand feet, board measure, for Pine stumpage, if there is any left fifty-five years hence.

small farmers in St. David's and other remote islands of the group. This nutritious starch, which is now used almost entirely as a delicate food for sick persons, is said to owe its name to Indians, who used it for neutralizing the venom from poisoned arrows.

Marshmallow-root, *Althea officinalis*, is at home in the temperate parts of northern and western Asia and the greater part of Europe, and has been naturalized in the salt marshes along the coast of New England and New York. The roots are collected in spring or autumn when two or three years old, the outer skin being removed in their preparation for market. They are sometimes used to give proper consistence to pills, as a demulcent and a poultice, and are credited with nutritious qualities. The blackish knotted rhizomes of *Helleborus niger*, with their many long brownish fibres, come from the mountains of southern Europe. The plant has an assured place in gardens for the late flowers known as Christmas roses. The ancients ascribed great power to Hellebore and used it for relief from such desperate diseases as epilepsy, some forms of mania, dropsy and scrofula, while its use is now comparatively restricted.

One of the most important exports from Mexico is jalap, the tubers of *Ipomœa purga*, and it also comes from Brazil. It consists of resin and starch almost entirely.

The rhizomes of Male Fern-root, *Aspidium Felix-mas*, and our native *A. marginale* are gathered in summer before they are a year old, since they soon lose their anthelmintic properties. Like many modern remedies this was also a medicine of the ancients and is mentioned by Pliny as a vermifuge.

Sarsaparilla may be the root of any one of several tropical American species of *Smilax*, principally *Smilax officinalis* and *S. medica*, and of *Aralia nudicaulis*, the wild Sarsaparilla of this country. These bitter mucilaginous roots are used in medicines and in syrups for flavoring. The Sarsaparilla from Honduras is most highly esteemed, and the Spaniards introduced the roots to Europe from Peru, Brazil and San Domingo as early as the middle of the sixteenth century, when they were supposed to be potent in serious blood diseases.

Perhaps 250 tons of dried Rhubarb-roots, *Rheum officinale*, are used in this country each year, most of the product coming from Shanghai. Pieces of the rhizomes, which are heavy and close, brittle and of lively color, are the best. As a medicine it combines the opposite qualities of a cathartic and astringent, and is also a tonic and stomachic, and helps digestion. A root which finds sale as a remedy for colic, but which is not considered officinal by the medical profession, is Masterwort, or Angelica (*Angelica atropurpurea*). The perennial purplish root is common in Canada, and in the United States as far south as the Carolinas, in marshy woodlands and meadows. Another once popular remedy, now but little used, is Mugwort, *Artemisia vulgaris*, formerly a favorite German remedy for epilepsy.

Pareira brava, the root of *Cissampeloo Pareira*, a climbing woody vine known as the Velvet Leaf, comes from South America. In Brazil it is used to offset the bites of poisonous serpents. It was introduced into European practice as long ago as 1688.

Years ago the Creeks and Cherokees in Georgia and the neighboring country collected Pink-root in their uncertain intervals of industry, and the plant was abundant in all the states south of the Potomac. The supply in time became smaller and fell short of the demand, but the western and south-western states now provide all that is needed, and casks and bales of it are forwarded from St. Louis by way of New Orleans. The rhizomes and rootlets of Pink-root, *Spigelia Marilandica*, are a powerful anthelmintic, and in South America and the West Indies *S. anthelmia* is likewise used. Overdoses are poisonous.

Zedoary is the trade name of the rhizomes of different species of *Curcuma*, especially of *C. zedoaria*. The outside of the short wrinkled pieces are gray, the inside being brownish red. It comes from the East Indies and is used

as a stimulant. The fibrous yellow roots of Gold Thread, *Coptis trifolia*, while not regarded as having medicinal qualities, are, nevertheless, sold in large quantities for their bitter tonic properties. The small evergreen plant is familiar near springs and in marshy places, and will be recalled by many as a local remedy of the country housewife for sore mouth in infants. It is offered in loosely matted masses of the long, thread-like, orange-colored roots, mixed with the leaves and stems.

Quantities of the odorous root of *Valeriana officinalis* are gathered by the Shakers of New Hampshire, and the industry extends to northern Vermont and New York. But the demand for this one-time fashionable nerve remedy is much too heavy for our home supplies, and many hundred-weights come yearly from the gardens of Belgium and the Netherlands—perhaps four-fifths of the entire supply—with smaller quantities from Germany and England. Valerian also comes from Japan, and the root from that country is said to be the richest in oil.

The root of our Blazing Star, *Liatris spicata*, and of *Aletris farinosa*, often seen in sandy woodlands, and both commonly known as Colic-root, are bought and sold under the name of Unicorn-root. The woody root of the perennial American plant, *Stillingia sylvatica*, Queen's Delight, is sometimes used in combination with sarsaparilla and other alternatives. From the Peruvian shrub *Krameria triandra* the blackish red, long-spreading root known as Rhatany is supplied to commerce. The bark of Sassafras-roots and the pith of the twigs, gathered after frost in autumn, have a recognized place in pharmacy in the United States, and the entire root is exported to England, where, as in this country, large quantities are used in making summer drinks. Parsley-root has an assured place in the wholesale drug trade, as have the roots of the dwarf Nettle, *Urtica dioica* and *U. urens*, of America and Europe, and the Musk-plant, the Pond-lily and yellow Dock.

While, perhaps, all the roots regularly quoted in the wholesale druggists' price-lists have now been briefly referred to, these are but a few of the many in regular use in medicine. For example, the rhizomes of *Cypripedium pubescens* may be bought by the hundredweight, and those of *C. spectabile*, *C. acaule* and *C. parviflorum* all have a market value, some of them furnishing a gentle nerve stimulant less powerful than Valerian. Horse-radish, though not named in the trade price-lists, is used for internal and external remedies. But the list of roots in general use might be extended indefinitely, even without mention of the living roots from which juices are obtained by incision, as the gum resin *Asafoetida* from the root of *Ferula foetida*, and Scammony from *Convolvulus Scammonia*, besides the roots of our commonly used vegetables and of those of native plants which have only been partially tested.

New York.

### The Cañon Winds in Utah.

THE country adjacent to the mouths of any of the mountain cañons of this state is subject to what is known here as the "cañon wind," a strong breeze which begins about nine or ten o'clock in the evening and continues till about eight o'clock the following morning. These winds occur almost every night from early spring until late autumn, and are felt over a considerable area of country about the cañon's mouth, being strongest, of course, near this point, and gradually decreasing in velocity as they spread over the surrounding country.

They exercise an important influence over the fruit industry of the state, their effect being decidedly beneficial in some ways and equally detrimental in others. Their most marked beneficial effect is in preventing late frosts, and in this way they often save the fruit crop from destruction. A prominent fruit raiser of Provo, whose farm is situated just at the mouth of Provo Cañon, states that he is successful almost every year with apricots, peaches and the early-flowering varieties of grapes, while one of his

neighbors, just around a spur of the mountain and not more than a mile or two away, but out of the range of the cañon wind, often lost his entire crop of fruit by the frosts.

The detrimental influence of the winds is confined principally to producing ill-shaped, one-sided fruit-trees, the branches leaning away from the cañon to a marked degree. This effect is much more noticeable in some kinds of trees than others. Apples and Plums seem to be most seriously affected, while Pears and Cherries are much less so. There is also a marked difference in the effect on different varieties of the same fruit, some sorts of Pears showing almost no evil effect whatever, while others, standing near by them, will be seriously distorted. I am of the opinion that this difficulty might be obviated to a considerable extent by judicious pruning from the time the tree is set; at least so far as the general shape of the tree is concerned. The smaller twigs on older trees might be less easily controlled. In cases where a dense and sufficiently high wind-break can be grown on the cañon side of the orchard the evil effect of the winds is much lessened, while the beneficial effects with regard to frosts remain the same.

Shade-trees are affected in the same way as fruit-trees, with the same difference in different species. Contrary to what might be expected, the tall, spire-like Lombardy Poplars show but little ill effect from the winds, but Box Elders, Elms, and even the Carolina Poplars, wherever exposed, are blown entirely out of their usual form and lean away from the cañon, as if to get as far from it as possible. This same difference is noticeable in Pears, the upright-growing sorts being the least affected. Small fruits are comparatively free from the evil effect of the wind, though occasionally it is severe enough to injure even these, if exposed, especially when the shoots are young and tender or at blossoming time.

Utah Agricultural Experiment Station.

F. C. Sears.

### The Care of Weak Limbs of Trees.

IN addition to misdirected efforts or mistakes in the pruning of trees, the results of errors in attempts to save broken or strengthen and support weak, but otherwise green and healthy limbs, are too often seen where trees are cared for. In many cases when a large branch or limb or part of the trunk breaks down to the ground, but still retains some connection with the main trunk, it is best, and will in the end prove most satisfactory, to cut off the broken portion and cover the wound with some one of the well-known substances to prevent the ingress of water, fungi, insects, etc.; or it may even be best to cut down the damaged tree and replace it by a new one. But in very many instances a little trouble and care would result in saving damaged trees for many years.

In supporting cracked, "wind-shaken," weak or overladen limbs, especially of Apple and other fruit trees, which have a tendency to split at the forks or crotches, poles are very often used as props, but this plan is hardly practicable in the case of large shade-trees, and, moreover, it is unsightly.

Limbs of trees liable to split in the forks or crotches are very often held together by placing an iron band or chain around two parts nearly opposite, so that they afford mutual support, and while this may seem to serve its purpose for a time, the increase in circumference and diameter of the limbs soon causes real injury by a process of choking or strangulation which ensues. Through their very small root-hairs and rootlets trees take up from the ground water and some other materials in minute quantities and crude form. This is carried up through the sapwood to the leaves, where it undergoes processes which prepare it for the making of new plant tissue. From the leaves the elaborated sap passes downward between the wood and bark of the stem, branches, branchlets, roots and rootlets, gradually forming new layers of wood and bark and increasing the diameter or circumference of all the parts. When the bark is unduly tightened by any strong band, wire, or even a strong string

Fig. 35.—The right and the wrong way to support a weak branch.—See page 274.

around it, the descending sap is obstructed and more wood will be formed on the upper side of the band than is formed below, and this increases year after year until the discrepancy may be very great. If the girdling is complete the part of the plant above the girdle is almost certain to die prematurely.

The accompanying illustration (see page 275) shows the effect of placing an iron band around two large limbs. Many years ago the band was tightened against the outer sides of the opposite branches, and now a considerable difference in diameter is seen in the portions above and below the girdle which encircles both limbs. The wood above has begun to grow down over the band of iron. Besides checking the proper growth and development of the plant, the trunk is structurally weakest at the girdled point.

Above the band and constricted portion appears in the illustration a simple iron rod running through the two limbs and treated as an ordinary bolt. In nearly all cases this is the simplest and by far the best system of supporting broken or weak limbs when they are opposite or nearly so. A rod of good iron from an inch to an inch and a half in diameter will bear an enormous strain, and is only necessary in the case of very large and heavy limbs, as of shade-trees. Of course, the strain is less, and a smaller bolt is required the higher up or farther away it is placed above the weak or broken fork or crotch of the limbs.

In a case as shown in the photograph, it is simply necessary to bore a hole straight through both limbs and bolt them together by inserting an iron rod of the proper length, having a large head at one end and a correspondingly large nut at the other, which should be screwed up tight. The rod should fit the hole as nearly as practicable, and a little wax, tar or paint may be applied around the iron where it enters the bark, so as to keep out moisture. After one season of growth any further care of this kind will be unnecessary, as the new tissue formed will have completely closed any opening around the iron. The hole bored does very little injury to the limb and soon heals permanently.

When the trees or branches are not too large or heavy, or when the rods are well up from the weak forks or crotches of the limbs, iron half an inch in diameter is amply strong enough. Where the rods are long and connect widely spread branches it is well to have them made in three separate pieces; two short bolts passing through the branches and a third connecting them, the inner ends of the bolts and the ends of the connecting third piece being provided with eyes or hooks. Made in this way there is no danger of the iron breaking by twisting caused by swaying of the upper branches, and such long rods are more easily fitted in place when in sections.

It is often worth while to preserve rare or valuable fruit or other trees which have split apart and fallen to the ground, but are still connected with the stump and are alive. By raising the limbs and connecting those opposite by several rods at various angles such trees may be preserved for many years.

Limbs of small trees and large shrubs which have become split apart may often be securely held together by simply screwing strong hooks into the opposing branches and connecting by strong wire.

The tree represented in the photograph is an American Linden, or Basswood, growing in a small front yard in the city of Boston.

Arnold Arboretum.

### Plant Notes.

**CALOCHORTUS PLUMMERÆ.**—This plant, otherwise known as *Calochortus Weedii purpurascens*, is, as Mr. Gerard has recently noted in these columns, a late-flowering species of the Butterfly Tulips. Its distinctness and quaint beauty deserve a special mention among July flowers. It grows vigorously although it has sparse foliage. Its large flowers are bowl-shaped, not reflexing on the margins,

as is common with most of the species. The coloring varies somewhat, but usually the upper halves of the petals are light lilac in color, and the lower parts greenish white. At the base also is a lilac marking like the arm of a Greek cross. The petals are of a satiny texture and lined nearly to the tips with profuse but short hair-like growths, which are sometimes purple and sometimes yellow. The sepals, which are wider than in most species, are lined with lilac and in some forms have dark blotches with hair-like growths. Some of the flowers sent to this office by Mr. Gerard are gracefully carried on long stems. They last well when cut and call forth the admiration of all who see them.

### Cultural Department.

#### Transplanting Pæonies.

**G**ARDENERS are well aware that the tops of *Lilium candidum* die down to the ground soon after the plants flower, when the bulbs take their rest, and in a few weeks begin to throw out roots and radical leaves which remain green all winter. The Oriental Poppy is another plant with large fleshy roots which behaves in the same manner, and, of course, the proper time to remove these plants is as soon as the tops have died and before the new roots have started for autumn growth. There are, however, many other herbaceous plants with fleshy roots the tops of which do not die down after flowering, while they send out a set of new roots in early autumn, which are probably useful in aiding to store up material in the root for the production of early flowers and seeds the ensuing year. Among plants of this class Pæonies may be mentioned, which are most successfully moved in this country in August. Owing to climate and exposure the most successful practice in English gardens differs much from that which prevails in this country, but the following advice from a late number of *The London Garden* is well worth considering in America:

An all-important item in the matter of Pæony culture is planting at the right time, and for this work no better time exists than the early autumn or late summer, by which I mean the end of August or during September. At this season of the year the plants will still be furnished with leaf and stem, and, preserving these intact, it is possible to lift and transplant a very large-sized clump of one of these Pæonies with the assurance that a good proportion of flowers will be forthcoming the year after. There are many who believe that planting or transplanting may be done at any time while the growth remains comparatively dormant, but let any such transplant a fair-sized specimen in September with all its foliage intact and another in January with no foliage and note the results. The one planted at the latter time will have many of its flowers blind in the ensuing year as a direct result of late planting. Nor is this all, since the same cause which has contributed to the blind buds will in all probability have produced a debilitated condition generally of the plant, though more particularly of its roots, that will not readily be overcome. A weakened root-action in a Pæony means a relatively weak growth, and from this an obviously weak bud at its base as the result. It may be thought that I have restricted the planting season to very narrow limits, yet I regard a certain season quite as important for these as I would for certain classes of bulbs to be planted before root-action commenced.

The whole subject of planting Pæonies turns on a question of roots, or rather the time and the manner these are produced, and when these facts are more generally realized the easier will it be to insure the planting of these within reasonable as well as seasonable limits. In Pæonies two sets of roots are produced in the year, the chief being in early autumn, and it is, therefore, to secure these intact that the planting should be done before they push forth. Planting done at a much later date either sacrifices these roots entirely or so mutilates them that they are of little value, and then the cry goes forth that Pæonies are difficult to establish. In point of fact, few things are more readily established when the work is done at the right time, but this is rarely the case. Lifted and planted when growth has well begun, and the plant has to exist all summer long on its own resources, it is little wonder the plants decline for a year or two or are slow to make a start at all. At Kew,

about two years since, some very large clumps were lifted, rearranged and replanted in full leaf in early autumn. Well planted, thoroughly soaked with water at the root, it was evident what the result would be the year after. Many of these plants, in fact, carried large, handsome blossoms, while to-day they are perfect examples and loaded with vigorous growths and flower-buds.

Next in importance to planting is the soil, which cannot be either too deep or too rich for these gross-feeding and vigorous perennials. Select a spot away from the roots of large trees and dig the soil as deeply as circumstances will permit, two feet, or three feet if possible. Work in quantities of well-rotted manure and bone-meal, old mortar rubbish and the like, also leaf-soil where this is plentiful and the natural soil very stiff or water-holding. So far as the soil is concerned, *Pæonies* will thrive in almost any that is deep and well enriched, but there must be no stint of manure, especially where hot sand or gravelly soils abound. In these latter it will be found a good plan to slightly sink the surface of the bed below the ordinary level, so that manure-water may be given freely at any time when needed.

#### Notes from Baden-Baden.

ALTHOUGH I regard Mr. W. Watson as a cultivator of highest rank, yet my experience with *Richardias* constrains me to differ widely from his views. I treat these plants much like *Kniphofias* or *Gladioli*; late in autumn, when the foliage withers, the corms are taken up, left to dry in the greenhouse, and afterward they are stored away in dry soil in a cool room until spring, when at the end of March they can again be planted in an outside border. A still better, but less convenient plan is to leave the corms outside, to cover them with some five inches of dry leaves and put on a sash or boards to keep off the wet. My plants are sturdy, clean, superabounding in health and very free-flowering; they are now in flower and continue to bloom until the end of August. *Richardia Nelsoni* has slightly mottled, large, heart-shaped leaves and flowers of a very attractive creamy white, with a shade of sulphur and a large violet-black blotch. It is a striking plant and sure to find admirers. *R. Adlami* is another still more remarkable new species. It differs from the former by its glaucous green and more sagittate leaves, which have no spots, and by its somewhat larger flowers in which the violet-black blotch is larger, extending often to two-thirds of the spadix.

A lovely plant is *Dierama (Sparaxis) pulcherrima alba*, with white bell-shaped flowers hanging and swinging on minute threads. This plant must either be kept in a pot or must have the protection of a frame. The Caucasian alpine, *Campanula mirabilis*, is now covered with hundreds of its beautiful bright blue flowers, forming a low pyramid, which attracts the notice of every one who passes it.

Baden-Baden.

Max Leichtlin.

#### Garden Notes.

IN Mr. Gerard's interesting notes on June Irises I do not find *I. Tingitana* mentioned, to my mind one of the most beautiful Irises of the bulbous section. It grows about two feet high and bears a flower as large as that of the English Iris, so called, but shaped more like that of the Spanish varieties. Its colors are blue of two shades, white and yellow. I cannot speak as to its hardiness since I have always protected it with hay during winter.

I have spoken of *Ixias* before. Mine have just passed out of flower and have been so exceedingly beautiful that I feel it almost a duty to say again if they can have a covering about three inches thick until the first of April they will go through the winter perfectly well and be vastly more satisfactory than if grown under glass. There are only two or three points to be observed: Plant three inches deep, waiting until the end of November, so that there shall be no danger of premature growth; cover with three inches of Pine or other leaves or hay, removing the same about the first of April, so that the shoots shall come strong, and take up the bulbs about the end of July. I have now in flower two varieties of what *Dammann & Co.* call their *Victorialis* strain of *Gladiolus*. They are almost the same as *G. Byzantinas*, but not quite as good. They are said to have the blood of some of the African species, but I see no evidence of it.

*Asphodelus ramosus* seems to be desirable when grown to a good size. A plant of it this year reached a height of nearly six feet, branching freely, and was covered with its fine white blossoms almost two inches across, with a thin red line down

the centre of each division. It really seems to me as fine as *Eremurus robustus* and much more easily managed.

The best things under glass at present are *Gloriosas* and *Gloxinias*. The shining, tendril-tipped leaves and the curious spidery flowers of the former are specially attractive. I once succeeded well in growing *Gloriosas* out-of-doors. They climbed on pea-brush to the height of four feet and made quite an unusual effect. I never could get them to do it again and have not tried of late. The nearly allied *Littonia modesta* is much hardier, and I no longer give it room in the house, but treat it exactly as I do *Gladioli*. Planted in the open ground it has no tendency to climb. As for *Gloxinias*, I cannot think it well to dispense with naming varieties. It is true that the average seedlings of the present day are much superior to those of twenty years ago, but it is also true that many varieties then existing were superior in substance and coloring to those which are shown now. As soon as we cease to preserve the best kinds (and naming them helps in this matter) we shall cease to improve the quality of the flowers.

I have used a label of my own invention for several years which I can recommend as satisfactory in general practice. No one kind is best for all purposes, but where permanence is desired I write the name with India ink or a soft lead pencil on a bit of paper, inclose in a small bottle and cork it. The bottle may be fastened to a tree with a copper wire, or when used for *Dahlias* or *Gladioli* it can be fastened to a stake of wood or wire. I have used these bottle labels for four years, and not one has been broken, and some have been used for *Ixias* and have lain out on the ground, winter and summer, since 1893 without breakage or loss. I use a kind called half-ounce Boston round. A gross cost me \$1.50, and corks for them ten cents more. I think they would give satisfaction for many purposes.

Canton, Mass.

W. E. Endicott.

**Opuntias and Sedums.**—The value of hardy *Opuntias* and *Sedums* as garden plants ought to be more generally appreciated. In the heat of summer they bloom finely, and that, too, in situations so hot and dry that few other plants can live there, much less thrive and flower freely. Instead of wilting in the sun, the flowers seem to rejoice in the heat, so that it is a pleasure to look at them. Just now, July 2d, the following are in full display here: *O. vulgaris*, *O. Rafinesqui* and *O. oplocarpa*. These are quite distinct sorts. The first has thick, fleshy joints, with comparatively small, deep yellow flowers; *O. Rafinesqui* has larger and flatter joints and rather larger flowers; *O. oplocarpa* has large, flat, very spiny joints, and its yellow flowers have a bright orange base. Large masses of these plants make a beautiful display. *Sedum album* and *S. speciosum* are also flowering now. Both are creeping or low-growing species. *S. speciosum* has rosy pink flowers, a rather uncommon color in the genus, and it is one of the best of all, both for its color and its profusion of flowers.

**Coronilla varia.**—Not many perennial plants flower for so long a time as this pretty leguminous plant. It is of creeping habit, or rather half-climbing, and does its best to clamber over brush when an opportunity is given it. The flowers begin to appear here in mid-June and they continue for a period of two months, and even later on a few flowers are displayed. The flowers, sometimes nearly pink and at other times pale purple, are in little heads of about twenty-five each. Like other plants of this genus, the foliage is usually pea-green. It is a native of southern Europe.

**Centaurea macrocephala.**—This is also a valuable summer-blooming perennial. The large heads of composite flowers on the various *Centaureas* are familiar to every one. This particular species bears large, clear yellow flower-heads on stems nearly three feet in height. To make an effective display large masses of it should be planted together.

Germantown, Pa.

Joseph Meehan.

#### Correspondence.

##### Notes from West Virginia.

To the Editor of GARDEN AND FOREST:

Sir,—This is the time of the year when *Hollyhocks*, *Yuccas* and tall *Lilies* are the most conspicuous ornaments of the garden. A few *Hollyhocks* were planted five or six years ago on ground enriched by an old woodpile, and since then they have been left to themselves. Here they have increased and multiplied in the rich soil, sending up many seedlings every year and grouping themselves in beautiful colonies. All shades of *Hollyhock* bloom are here, from white through the palest flesh tints to deepest maroon, varied by buff and lemon-tinted

flowers. All are in perfect health, and having crowded out the weeds that originally fought with them for mastery they are now in full possession of the soil. Hollyhocks are ideal plants for waste places such as this.

Here at Rose Brake we like to use a good deal of discrimination in the arrangement of flowers so as to make them blend harmoniously, and we are fond of scattering herbaceous and even some annual plants among our shrubberies. Thus, a group of spring-blooming shrubs in a prominent position is now carpeted with yellow and orange Nasturtiums, while tall orange-colored Milkweed is blooming here and there among them. These bright flowers, shining amid the healthy green of the shrubbery, form a charming picture which would be quite spoiled, it seems to us, by the admixture of any other color.

In another place the deep red *Monarda didyma* grows luxuriantly among some Oak-leaved *Hydrangeas*, now in full flower, and here the large creamy trusses of *Hydrangea* bloom contrast well with the rich carmine of the *Monarda* flowers. These simple effects are much more satisfying to the eye than the bewildering jumble of discordant colors seen in so many gardens, which want of space and a desire for great variety combine to spoil.

*Spigelia Marylandica* is a pretty companion for *Monarda didyma*, and is now in full bloom. It should be planted in partial shade as it does not thrive in full sun, and it needs a deep, rich, moist soil. The latter condition we have to supply by frequent watering and mulching, as none of the soil on our dry hillside can be called moist. The *Spigelia* belongs to the small family of *Loganiaceæ*, of which *Gelsemium semper-virens*, the so-called Yellow Jessamine of the south, is, perhaps, the most conspicuous member. The *Spigelia* is about a foot in height and bears numerous beautiful tubular blossoms of bright red lined with yellow.

Foxgloves have been very fine this year, and are now passing. These are best away from scarlet flowers, as their tall spikes of purplish pink blossoms do not harmonize with red. But the tall pure white Foxgloves are effective almost anywhere, and especially when seen in bold groups with a background of dark foliage they have a stately effect and remain a long time in flower. All Foxgloves are easily raised from seed and bloom the second year after planting. We plant ours in the open in April, where they take care of themselves; all the attention they receive is an occasional stirring of the soil around their roots and thinning where they are too thickly planted.

Rose Brake, W. Va.

*Danske Dandridge.*

### Dodder in Clover.

To the Editor of GARDEN AND FOREST:

Sir,—Two letters within the last twenty-four hours have been received at this station, with samples accompanying each, in regard to Dodder upon Clover. There is a mingled feeling of wonder and fear expressed in both of the communications, and as Clover Dodder is not a widespread and common enemy in this country a note on the subject may be useful. Last year I sent a brief article to GARDEN AND FOREST concerning Dodder upon the Onion and Eggplant on some large truck farms. And now one correspondent writes that while cutting his clover "the machine would suddenly enter a thread-like mass which clogged it completely. After cutting, the mass soon wilted and formed a sort of blanket which could be rolled up. . . . There were about fifteen of these beds, averaging six feet in diameter to the acre. Since cutting (some ten days ago) the Clover has made a good start over the entire field, except where this growth occurred. In these beds everything is as dead as if burned over with fire. Around the edges of these bare patches a new growth of this fibre has started vigorously, and if not checked may overrun the whole field." The second complaint speaks of the growth as found in spots all over the field, "forming a dense mat, almost obscuring the Clover-stems when cut off. . . . In some places the Clover is killed."

These extracts show how active the Dodder may become when once it gains a foothold in the Clover-field. Of course, both writers ask how the growth got into the field and what is the best method of eradicating it. In the one case the land bearing the Dodder has "been under cultivation for fifty years." The other was pasture for twenty years, and then plowed for Corn, followed by Wheat and Clover.

The seed of the Clover Dodder, *Cuscuta epithymum*, is nearly the same shape as that of the clover, but not more than one-fourth as broad or long. It could be easily separated from the clover by an ordinary fanning-mill with properly adjusted sieves. It is not unlikely that it came in with manure. Under

the circumstances it is impossible to be certain as to the way the entrance was made.

The fact that it is a seed-bearing parasitic pest should put all who have the Dodder in their fields upon their guard against permitting the seeds to get into the manure. All patches of the plant should be raked up and burned along with any clover to which it may be attached. It is worse than a weed because it grows upon the plant and demands specially thorough treatment.

Experiment Station, New Brunswick, N. J.

*Byron D. Halsted.*

### Pear Blight.

To the Editor of GARDEN AND FOREST:

Sir,—I send you some twigs of a Pear-tree on which the leaves and young fruit seem to be affected with some disease. Will you please tell me specifically what it is and how it should be treated?

Jenkintown, Pa.

*G. F.*

[This is the well-known fire-blight which is now supposed to be due to a bacterium which enters the plant through the tender parts of the tissue, like the flower-buds or young leaf-buds as they unfold, and spreads down through the branches. When it appears on the main branches it is often called "body blight," and its presence is marked by brown and lifeless patches which become sunken. Wherever the blight appears the limbs should be cut off at once below the point where the infection has reached, and as a precaution against the spread of the disease the prunings should be burned.—Ed.]

### Two Insect Pests.

To the Editor of GARDEN AND FOREST:

Sir,—Upon a fine young Butternut, planted two years ago in a natural grove of Oak and Hickory, I lately discovered signs of the destructive work of some insect. The leaves were yellowing and worm-eaten and many of them falling. Closer examination showed that the mischief was due to worms about an eighth of an inch in length, their backs tufted with a snowy white filamentous growth resembling cotton or wool. Professor John B. Smith, the Entomologist of the New Jersey Agricultural Experiment Station, to whom samples were submitted for identification, writes that the insects are ordinarily rather rare, and that this is the first time he has met with them in this state. The species is known as the Butternut woolly worm. It is the larva of one of the sawflies, and will succumb readily to an arsenical spray. Even a weak mixture like one pound of Paris green in two hundred gallons of water will be sufficient to kill off the insects if they are really abundant enough to be troublesome. The tree in question is the only Butternut known to exist in the neighborhood, and it would be interesting to learn how its natural enemy has discovered it so quickly.

*Phytomyza Aquilegiæ*, after resting from its labors last season, has now begun active work upon my large collection of Columbine-plants. There was not a sign of it until about ten days ago, but now the leaves are badly mined, showing in curious tracery the meanderings of the grub. It is an aggravation that no insecticides avail against this insidious footless pest. The Columbines blossomed in all their glory, however, before the attack began.

Inwood, New Brunswick, N. J.

*S. de L. Van Rensselaer Strong.*

### Gardens for Public Schools.

To the Editor of GARDEN AND FOREST:

Sir,—In your issues for May 5th and April 21st are articles on school gardens, based on some work done at the Cornell Experiment Station, and they give the impression that this is the first experience of the kind in America. You say, "a correspondent writes to inquire why the obvious plan of having a garden attached to every school has not been suggested." Your correspondent evidently is not aware that the Massachusetts Horticultural Society has been suggesting this for six years past and has sent out thousands of reports on gardens connected with schools near Boston. I send you a prize list as an evidence of the work done by the Massachusetts Horticultural Society since 1891.

Roxbury, Mass.

*Henry L. Clapp.*

[The list contains a schedule of prizes for school herbairiums, and the society also offers one prize of \$15.00, one

of \$12.00 and one of \$10.00 for gardens stocked with native wild flowers, such as Ferns, Grasses, Asters, Golden-rod, native shrubs, economic plants, such as grains, vegetable roots, leguminous and cucurbitaceous plants. What are known as ornamental plants commonly cultivated in gardens are not admitted into the school gardens for competition. In determining the prizes reliance is placed mainly on the principals in charge. The names of the plants and the uses actually made of them must be accurately described.—Ed.]

### Recent Publications.

*Mountain Climbing.* Charles Scribner's Sons. New York. 1897.

In this torrid weather a table of contents, with chapters on Mount Washington in Winter, Mount St. Elias and Its Glaciers, A Thousand Miles Through the Alps, and The Ascent of Mount Ararat, ought to have some refrigerating influence. The illustrations show fields of everlasting snow, with cliffs and peaks of ice, frost feathers everywhere, and fur-clad climbers who only seem to need the exhilarating influence of a blizzard to make them entirely happy. These illustrations, of which there are something like a hundred, are, as a rule, unusually effective, although they differ very widely in character, and range from those which show the delicacy, refinement and finish of Mr. Jaccaci's touch to the mechanical but thoroughly good reproductions of photographs in which the engraver's tool has turned the half-tone into a genuine work of art. There are seven articles in all, written by Edward L. Wilson, Edwin Lord Weeks, Mark Brickell Kerr, William Williams, A. F. Jaccaci, H. F. B. Lynch and Sir W. Martin Conway, and they have been gathered together into this volume from the pages of *Scribner's Magazine*, where they first appeared at different times. The essential unity of the book is found in the spirit of the mountain climber which pervades it, and this is one the world over, from Ararat to St. Elias. There is the same joy of battle with the forces of nature, the same exhilaration at conquering dangers which are by no means imaginary, the same cheerfulness and good humor which is essential to success, for, however querulous or pessimistic a mountain climber may be elsewhere, when he is once above the clouds with his life in his hands and toes he is the most genial of comrades, the most devoted and self-denying of friends. All the chapters are well written, and one almost gets a surfeit of panoramas of desolation, vast silences and solitudes of ice, the yawning blackness of bottomless chasms, and winds and storms which enjoy themselves in a wilder way than they do anywhere within a mile of the sea-level. Other travelers occasionally take pains to tell something of the life of the regions they explore; they make friends with trees, shrubs and humbler plants, and with the animals, birds and insects which they encounter; but the mountain climber scales his peak and sees little else but the mountain and the broad features of the earth which are spread out beneath his feet. This lack of scientific investigation, however, can be forgiven, and, indeed, drudgery of this kind seems too prosaic for these pilgrims possessed with an absorbing passion. The stimulus of the mountain climber is really a moral one, and anything so earth-born and unimaginative as a longing for knowledge would seem to be altogether too tame to make an effective appeal to his adventurous spirit. Physical trials like those which face the confirmed mountain climber can only be overcome under such excitement as the soldier feels when going into battle. Altogether, it is a pleasant book to pick up, and one can hardly read a page without coming on some such passage as this in Sir W. Martin Conway's chapter entitled "A Thousand Miles Through the Alps":

The finest scenery in this part of our journey at the west end of the famous Bernese Oberland was that of the glacier of the great Dead Plain. We did not see it until we were on its edge and the white expanse spread before us. It fills an elliptical hollow some two miles long by a mile wide, and once

on its smooth large surface the external world is shut out by a ring of low mountain wall. Not a trace of human activity can be seen in any direction. The largeness, simplicity and seclusion of this strange snow-field make it unique. We traversed its longest diameter, and the hard surface was beautifully rippled and perfectly clean.

### Current Literature.

An interesting monograph on the Peach industry in Pennsylvania has been prepared by Professor Butz, and published as Bulletin No. 37 of the Agricultural Experiment Station of that state. The industry is only twenty-five years old, and yet the area in Peach orchards in Pennsylvania is estimated at 11,000 acres, or something like 2,000,000 trees all told. Most of these are found in three or four counties in one or another of what are known as the Peach belts of the state. The largest of these sections is the Juniata Peach belt, located principally in Juniata County, but extending into Mifflin, Perry and Snyder counties, comprising together some 3,500 acres. The next largest district is the South Mountain belt, lying within Franklin County, but extending across Maryland to the Potomac River. In both these belts the orchards are on hills, the latter embracing the western slope of South Mountain, where there are now planted some 400,000 trees, with the prospect that the entire slope will soon be devoted to this industry. There are single orchards that contain from 6,000 to 8,000 trees, and one orchard contains at least 10,000.

The one hindrance to Peach growing in Pennsylvania which cannot be entirely overcome by human foresight and effort is the winter-killing of fruit-buds. It is not the degree of temperature only which causes this destruction, but several other obscure conditions, besides unripened tissues and drought. A more or less complete failure of fruit by winter-killing seems to happen at least once in four years. While there are many insects which are enemies to the Peach, the only one to be dreaded seriously is the borer, and this can be controlled by careful examination in spring and fall, and when an attack is discovered the offender is dug out with a knife. This is tedious work, and it requires to be done by a trusty man, but the remedy is sure. The mysterious disease known as the yellows is working an increasing amount of damage. It is contagious, and no one knows a remedy for it. Whenever a tree shows symptoms of the malady, even if it is young and strong, the trunk is blazed and the next winter it is cut down and burned. If these things are attended to and the ground is stirred every year from May to July inclusive, a paying crop can be counted on. Fertilizing with potash salts and phosphates, with Crimson Clover or some other leguminous crop to gather nitrogen, has proved remunerative, and, of course, the practice of thinning the fruit has proved beneficial here as elsewhere, not only to the immediate crop when quality and profit are considered, but also in preserving the health and vigor of the trees. The practice of using smaller packages is growing, and the so-called Michigan basket, with a handle, a raised lid and a capacity of twenty pounds, is favorably spoken of. There are more small families than large ones, and purchasers more frequently want a peck or a half-peck than a bushel, and they will therefore more readily buy a small package which they can conveniently carry away than a larger one.

Among the most profitable varieties which ripen in the South Mountain belt from September 25th to October 17th are the White Heath Cling, Salway, White Heath Freestone, Bilyeu's October and Levy's Late. Varieties which prove good on both high and low land are Crawford's Early, Crawford's Late, Mountain Rose, Reeve's Favorite, Moore's Favorite, Old Mixon Free, Stump, Chair's Choice, McAllister and Fox Seedling. Susquehanna is a variety which originated with a Mr. Griffith in this state; it is a large yellow-fleshed, red-checked peach of superb quality and ripens late in August. The tree is not a prolific bearer, however, and therefore it is not often planted for market. In

commercial orchards planters remember that the market prefers yellow-fleshed peaches to white-fleshed ones, even though the latter are of better quality. Peaches like Mountain Rose and Bilyeu's October are white-fleshed, it is true, and they are planted, but this is because of their productiveness. A cling-stone peach should be avoided as one avoids an enemy. The only clingstone planted largely in Pennsylvania orchards is Alexander, and this is tolerated because it is the earliest to ripen.

### Notes.

Tender asparagus is scarce and sells at twenty-five cents a bunch. Sweet corn, from New Jersey, is as yet immature, and the best seen last week came from North Carolina. Tomatoes seem uncommonly poor, and, although they now come from near-by fields as well as from the south, they are too costly for general use and are sold by the pound and quart. Many are sun-burned and blistered. The first Lima beans, from Florida, were offered last Saturday.

The annual report of the City Parks Association of Philadelphia has just come to hand, and it seems to be a record of considerable success in the useful work of securing open spaces, planting trees, providing playgrounds and saving, so far as can be, the natural beauties of the land over which the city is extending. Since the establishment of this association something like thirty pieces of ground have been secured, ranging from thirty acres in size, downwards, and it is hopeful that the disused burial grounds of the city will soon be thrown open for public use, and that funds for the proper development and management of the recently acquired grounds will be obtained.

According to the *Washington Star* more than 20,000,000 packages of seeds have been distributed by the Department of Agriculture this season, at an expense of \$130,000, each member of Congress having 40,000 packages to dispose of. There were more than a million packages of flower seeds, nearly half a million packages of field seeds, and, of course, vegetable seeds in great variety. Thirty-two kinds of beans, twenty-three kinds of cabbages, thirty of lettuce, and nineteen of muskmelons indicate the wide range covered by the list. The entire amount of seed distributed would have planted more than three hundred and fifty square miles, the largest distribution ever attempted by the Department. The *Star* might have added that this is one of the most disgraceful swindles ever perpetrated by a civilized government.

A correspondent of *The Gardeners' Chronicle* praises several named hybrid *Hemerocallis* which have been produced by a Mr. Yeld, of Clifton, Yorkshire, from crosses between different species of this genus. Some of these are described as valuable plants, and one of them, a hybrid between *H. flava* and *H. Sieboldii*, is said to be remarkably showy and distinct. It grows vigorously, has sturdy flower-stems thirty inches high, each bearing eight or ten orange colored flowers four inches in diameter and three inches long. The buds are a brownish purple and highly polished, and this color is retained on the outer segments after the flower has fully expanded. The prolific character of the plant may be estimated from the fact that in a space about two feet square forty flower-stems were carrying something like 360 flowers. The different species of *Hemerocallis* are so beautiful that they offer a most promising field for the hybridizer.

Mr. W. Botting Hemsley states in *Knowledge* that the characteristic form of the tall-growing Gum-trees of Australia is a massive trunk, branchless to a great height, and a comparatively small crown, with the ultimate branches slender and drooping. In some species the bark is smooth and polished like that of the Beech; in others it flakes off, as in the Plane-tree. The Blue Gum, *Eucalyptus globulus*, although it is less than half a century since its value began to be realized, probably has a more extensive literature than any other tree. *E. amygdalina*, in its fullest development, is probably the tallest of trees. A prostrate tree of this species was found to be 420 feet long and 295 feet up to the first branch, where the trunk was four feet in diameter, and at 360 feet it was still a yard through. The Karri, *E. diversicolor*, and the Jarrah, now used extensively for street paving in London, are both trees of enormous magnitude. There are many records of trunks between twenty and thirty feet in circumference at five feet from the ground, and Mueller mentions a buttressed Jarrah-

tree which girthed sixty feet at six feet from the ground. It may be added that a cubic foot of green Jarrah wood weighs seventy-five pounds, and when dry about sixty pounds.

The recognized method of destroying weevils and other seed-infesting insects which cause serious loss to seed and grains both for sowing and for food purposes, is to treat them with the fumes of carbon bisulphide at the rate of one pound to a hundred bushels. This chemical is a colorless liquid, but when exposed to the air the sulphur and carbon separate, each uniting with the oxygen, forming carbon oxide and sulphur dioxide, the latter of which is a very poisonous gas with a disagreeable odor. To ascertain whether seeds treated with this chemical lose their germinating capacity an experiment was made by the Division of Botany in the Department of Agriculture, in which seeds were exposed to a saturated atmosphere of carbon bisulphide for forty-eight hours. They were then placed in a germinating chamber in which check lots of untreated seed were also tested. The result was that the germinating percentages of almost all the seeds treated and untreated were the same, although in barley, rye, wheat, corn, crimson clover, millet and rice this extreme treatment caused some injury. The varieties which were damaged by an exposure of forty-eight hours were then put to another test of twenty-four hours' duration, and the result seems to be that in general the seeds of cotton, peas, beans, buckwheat, oats, the cabbage family and cow peas will endure severe treatment with the fumes of carbon bisulphide without losing their germinating quality to any appreciable extent, while on the other hand seeds of corn, wheat, rye and crops belonging to the grass family, except Kaffir corn and oats, should be treated with caution, since a deterioration in vitality is likely to result from excessive exposure to the gas.

The great quantities of beautiful California cherries which have made so bright a showing on the fruit-stands for a month past are steadily decreasing, and only small consignments of Oregon, Royal Anne, Black Republican, Black Tartarian and Black Bigarreau came last week in fifty-two car-loads of fruits from the Pacific coast. Bartlett pears are now of good size, as are Clapp's Favorite, and good California peaches are fairly plentiful and include such varieties as the favorite early Alexander, the juicy white-fleshed Hale's Early, Governor Garland, the choicest of all the early peaches, and having delicious flavor and fragrance; Briggs' Red May, a standard early sort since 1870, and the highly flavored yellow St. John. There were Royal, Silverskin, Moorpark and Blenheim apricots, and some showy large Red Astrachan apples. Plums and prunes were never so plentiful here and so varied in color and form, and this fruit comprises the bulk of the great quantity now arriving. Among the popular and highest-priced varieties now in season here are the medium-sized, dark purple Tragedy prune, with rich, sweet yellowish green flesh; the French Peach plum, large, roundish, with shallow suture, and varying in color from salmon to brownish red; the reddish flattened Simoni plum, with deep cavities at base and apex, and apricot-yellow flesh of aromatic flavor; Burbank, a very large, nearly globular plum, rich cherry-red in color, slightly mottled with yellow and freely dotted with the same color, having a distinct flavor. Ogon, Abundance, Parsons' Early, Clyman, Royal Hative, St. Catherine, Wickson, Purple Duane, Washington, Pedro, Hungarian, Yosabi, Satsuma and Botan are all seen and make a remarkable display of color and form. Fresh figs are also more abundant than in any former year, and sell as low as 60 cents a dozen. The leading late varieties of peaches are now coming from Georgia, but these are hardly up to the average in quality, owing to curculio sting, and sometimes to decay. Exceptionally large Georgia peaches known as Belle sell for \$1.00 a basket holding twenty of the fruits. Strawberries, raspberries, currants and other small fruits proved very perishable during the hot days of the past week, and while good fruit cost the householder ordinary prices, large quantities of soft berries were bought up by makers of jams and syrups at unusually low rates. Lemons advanced \$1.00 a box as a result of the hot weather, and the best Palermos brought \$5.12½ wholesale at auction. Nearly 200,000 boxes of this fruit are on the way from the Mediterranean, but only two cargoes are expected here this week, so that if the heat continues even higher prices are certain. The shortened supply of bananas from Cuban ports has been made good by extra shipments from Central America, and during June 561,000 bunches were sold in this city to retail dealers, an increase of 31,000 bunches over the amount handled in the same month a year ago. A few of the delicate little Lady-finger bananas were among these importations and are occasionally seen in the fancy-fruit stores.

## Legislation Against Plant Pests.

THE brown-tail moth is not a rare insect, and it has been known to entomologists for many years as *Liparis* (or *Porthesia*) *chrysorrhœa*. It has never been known in America, however, until the spring of the present year, when it was detected in Somerville, Massachusetts, and since it is almost as omnivorous and destructive as the gypsy-moth, to which it is closely akin, the discovery of the new immigrant caused something of a panic. The Governor of the state wrote a special message of warning, and about a month ago a law was approved which aims to compel local authorities to take active measures for its suppression. The law provides that whenever this pest shall be discovered in a city or town of Massachusetts the local government shall take immediate steps to destroy it and prevent its spread. If they are in doubt as to the identity of the insect they shall notify the Board of Agriculture, which Board thereupon must inspect the region and supply printed directions setting forth the most approved methods for the confinement and extinction of the insect. Owners and managers of infested premises, as well as mayors and aldermen and selectmen of infested towns and cities, who neglect or refuse to comply with the requirements of the act are subject to fine or imprisonment. If this moth is still confined to a small section of the state the effort to suppress it may not be utterly hopeless. But it may have been half a dozen years ago when it was imported, and further examination may show that it has been widely distributed, so that we ought not to be too sanguine about its utter extermination.

But, whatever the merits of this particular law against this one pest, it is certainly worth while to discuss the general principles upon which legislation against insects and fungi injurious to vegetation ought to be based. We legislate against contagious diseases of man by quarantine, by enforced vaccination and by other sanitary regulations. We have laws for stamping out infection among domestic animals. Almost every state in the Union makes it a misdemeanor for a landholder to allow noxious weeds, like the Canada Thistle, for example, to go to seed on his premises. The principle which underlies all these laws is the same as

that which holds the owner of a Cranberry-bog in New Jersey responsible for the scald on his plants, and which in a dozen states compels the destruction of Peach-trees affected with the yellows, or Plum-trees with the black-knot. The assumption is that no man has a right to permit his premises to be a breeding-ground for pests which will bring loss upon his neighbors, when by due diligence he can prevent this. If the trouble does not come from his own carelessness it is right that the state should pay him, as it pays for the destruction of diseased cattle.

But if we admit that legislation against plant pests is justified on this ground, our laws may only be effective to a limited extent. If New York enacts and attempts to enforce a law against the San José scale, for example, what is to prevent an invasion of these insects from adjoining states where there is no restriction upon its spread? To meet such a difficulty Federal legislation has been invoked, and this might be effective with state coöperation as it was when Congress authorized the Department of Agriculture to eradicate pleuro-pneumonia by slaughtering cattle and paying for them what it saw fit. Massachusetts three years ago asked the General Government for an appropriation of \$100,000 to aid in exterminating the gypsy-moth, but under our system of government such assistance can hardly be hoped for, and unless, therefore, the states all unite in the enactment of similar laws, any attempt of a single state to compel its inhabitants to fight a moth or a fungus is as likely to prove ineffective as was the Papal bull against the comet. Again, state laws against the enemies of plants, however well considered, are liable to failure in execution, because of a sluggish public opinion that refuses to enforce them. Noxious weeds go to seed by every wayside in spite of legislation and governments. Locusts continue to ravage the western states, although their statute books order farmers to plow the land where these insects have laid their eggs. Over and over again juries have failed to convict peach growers when it had been proved that they refused to burn trees affected by the deadly yellows. This is simply because there is not a public sentiment behind the law strong enough to compel its enforcement. The canker-worm and tent-caterpillar have probably done ten times as much injury in eastern Massachusetts as the gypsy-moth, but a public sentiment which is not strong enough to arouse the people to a destruction of these pests would not enforce a law leveled specially against them.

But it does not follow that because the enforcement of a law is not certain, it is therefore unwise to enact it. It is true that habitual disobedience to any law breeds, to a certain extent, contempt for all laws, but it is also true that the expression of the intelligence of a commonwealth on its statute books is of itself an educating force. Laws against forest fires, for instance, help to instruct people who have never given the subject attention as to the enormous amount of property they sweep away. In the mean time nothing should be neglected which helps to disseminate knowledge of plant pests and their ways. It has been estimated that a million and a half of dollars every day would not pay for the losses inflicted upon agriculture throughout the United States from insects and fungous diseases. It matters little whether the exact figure is larger or smaller than this. It is sufficient to know that the tax upon the productive resources of the country from these sources is enormous. If we are not yet prepared to enforce wholesome laws to prevent this loss, we certainly ought to do everything possible toward creating a sentiment which will enforce them. Here are matters which should be subjects of study in the common schools to begin with, as well as in the agricultural colleges and bulletins from our experiment stations and in farmers' institutes. A civilized people cannot afford to go blundering on as we are doing now, when united action would protect us from a great portion of this loss. When we are confronted again by some new enemy like this moth from Europe there ought to be sharp eyed boys and girls in every state who would detect it at once, and their fathers should have machinery

ready for such an emergency, and be able to check the outbreak at its very beginning.

MR. WILLIAM ROBINSON dedicates the fifty-first volume of *The Garden* to the Rev. G. H. Engleheart, who is best known for his work in hybridizing Narcissi. In a note accompanying a good portrait it is stated that Mr. Engleheart has devoted his leisure for the improvement of Narcissi for sixteen years past with even more remarkable success than characterized the work of his kinsman, the Hon. and Rev. Dean Herbert, sixty years ago, for, besides enriching our gardens with new creations, he has studiously traced and verified the almost unrecorded labors of other workers in this field, such as Backhouse, Leeds, Horsfield and others, until the rearing of Narcissi has been brought almost to the precision of an exact science. Mr. Engleheart has remade these seedling forms, so that now, for the first time, we know their pedigree, and in a similar way he has verified the parentage of many wild hybrids and seedlings which have until lately ranked as true species, although Herbert surmised long ago that some of them were of hybrid origin. Many of his hybrids and seedlings have received first-class certificates and many more have received medals and other rewards. The Trumpet Daffodil, Ellen Willmott, is spoken of as the very finest seedling raised, and White Queen, one of the new peerless forms, is almost equal to it. In Red Prince, Beacon, Southern Star and Oriflamme we have intense color added to perfect form and good substance, with cups almost scarlet and crimson. The seedlings of *Narcissus poeticus* are genuine improvements on that admirable plant, being better in form, size and color, while the rather tender hybrids of *N. triandrus* seem to be the perfection of daintiness and grace when grown in pots or in the house.

#### The Landscape-gardener and his Work.

MR. O. C. SIMONDS, of Chicago, who prefers the title of Landscape-gardener to that of Landscape-engineer or Landscape-architect, published an article in a recent number of *Park and Cemetery* which contains a good statement of certain elementary principles in his art. Some of the more important passages in this paper are here reproduced:

When one considers engineering in connection with landscapes, instead of thinking of any artistic production, one is more apt to think of the scars along mountainsides, of the destruction of beautiful scenery along river banks, of the changing of watercourses into sewers, of railway embankments, canals and dams. The term "architect" brings to mind a man who aims to design artistic structures. His materials are stone, brick, the various metals, wood, glass, paint, etc. If the term landscape-architect had not been used by some of the foremost landscape-gardeners in this country one would imagine it to designate a man who designed summer-houses, pavilions, balustrades, fences, hedges and things with stiff and formal lines. On the other hand, the term landscape-gardener has, first, "landscape," which, as defined by Hamerton, implies a consistent picture, and "gardener," which indicates that the materials used will be those found in a garden. The objections made to this term come primarily from those who regard a garden as a place in which to raise vegetables for the kitchen, but garden, which meant originally an enclosure, has long signified a place that gives pleasure by the arrangement and beauty of its trees, shrubs and flowers. Mrs. Van Rensselaer has happily called the pleasing effects produced by judiciously arranged masses of foliage, flowers, lawns, water and varied land surfaces, Art Out-of-Doors. To become acquainted with the principles and literature of this art one must read what Repton, Loudon, Downing, Kemp, Robinson, Olmsted, Parsons, Mrs. Van Rensselaer and others have written on landscape-gardening. So far as I am aware no one has written a book on landscape-architecture.

What are the attainments of a skillful landscape-gardener? He follows a fine art which appeals to the eye and has to do with what we see as we pass along residence streets, boulevards and parks. His art applies to any outdoor scenery which can be affected by the hand of man. It is of the first impor-

tance, therefore, that he should know how to arrange the ground surface, the trees, shrubs and other plants, the ponds and streams, the points of view and the open spaces or vistas, so that the general effect will be pleasing. No matter how great his knowledge of soils, of drainage, of road construction, and of the structure and characteristics of the various species of plants may be, if he fails to make an artistic arrangement he is not a landscape-gardener.

Next in importance to a knowledge of arrangement comes the ability to produce a result which, with a reasonable amount of attention, will continue to improve with added years of growth. This ability will rest in part on an acquaintance with the habits and life-history of the plants used and of the situations to which they are adapted.

The proper location of the points of view will require a study of the relations of buildings, drives and walks to the landscapes. Where the landscape is an important feature the landscape-gardener should work with the architect in the preparation of the preliminary sketches. Unfortunately, architects frequently design residences and other buildings without any regard to the site and the characteristic features which may have attracted the owner. Cases are not unknown where houses have been so designed and placed that the kitchen and servants' rooms shut off the very best views from the family living-rooms.

A landscape-gardener should be skilled in what Mr. Olmsted calls "the anatomical plan." He should not only be able to place drives where they will command good views while not interfering with the landscape, but he should know how to place them so they will be convenient, with easy grades and proper drainage, and how to construct them in a durable manner with a satisfactory wearing surface. He should know how to economize in regard to space and the cost of the work coming under his direction. While he should have no pecuniary interest in any work that is carried on—that is, should have no interest in any nursery or greenhouse or act as agent for any firm—he should usually purchase the material furnished by nurserymen on account of his knowledge of what is required, the prices that should be paid and the standing of the various nursery firms. He will often be able to save an owner several times the amount of his fees by his knowledge of the value of plants. His work should commence with a study of the adaptability of a given piece of ground for the purpose intended, especially when that purpose is the making of a park, a botanic or public garden, a cemetery, home grounds or the location of a public street. The ground in question may have features which would be of great importance in the design to be worked out, such as an important view of a large body of water, a valley or a distant stretch of country, a grove of trees which would require many years to grow, a rocky ledge, a steep bluff or a ravine, or it may lack valuable features which could be secured by the selection of another piece of ground. When the site is finally selected, a thorough study should be made of its characteristic features and of all the surroundings, and after such study the landscape-gardener should have as clear a conception of the effect he wishes to produce, of its appearance when the first planting shall have been done, when one, two, three, ten years have elapsed, as a painter has when he begins work on a canvas. Not only that, but he should have in his mind the various effects of spring, summer, autumn and winter.

Having made his design, and perhaps sketched it on paper ("perhaps," because a sketch is not always necessary, and there are cases in which the best result will be produced by working directly on the ground), he proceeds to execute it just as his brother artist proceeds to paint a picture, but instead of putting a background on canvas he shapes the actual ground, mixing with it compounds of nitrogen, potash, phosphorus, etc., which, dissolved in the rain, by the aid of the warmth and light of the sun, will afterward produce the desired colors. The landscape-gardener, however, does not select his colors directly. If he wishes a dark green carried up from a given place on the ground he chooses a Maple, or if the green is to continue through the winter he chooses a Pine as his servant to gather the materials already found or placed in the ground. If he wishes a red in winter he chooses a Dogwood, which will put this color in its bark, or if he wishes a red in summer he may choose a Rose. By choosing the right number and kind of such helpers a great mass of color may be carried high into the air, or spread out on the ground like a carpet.

Whether the living picture, as a whole, will be satisfactory or not will, however, depend upon the choice of material made by the landscape gardener, provided his supervision is continued for a long enough time. The continued supervision is required because it takes time—in some cases years—

for the various trees, shrubs, vines and herbaceous plants to do their part in making the picture. More are needed at the commencement than are needed later. They are not large or strong when first assigned their places. Some may become sick or they may crowd their neighbors. The owner of a place or his man in charge, or the superintendent of a park, may have failed to grasp the features of a design, and so have made changes detrimental to the final result. Few members of the profession, to say nothing of the clients, have appreciated the importance of an oversight extending through a series of years. The architect's work is finished with the completion of a building; the painter's when he puts his last touches on a canvas, but what the landscape-gardener must have in mind is not a single picture, but a series of pictures having more or less resemblance to each other, changing more rapidly with the first than with the later growth, and needing from time to time the inspection and criticism of a trained eye. This inspection may be made by visiting a place once a year, once a month, or even more frequently, as may be agreed on with the client, but it should not be omitted.

Perhaps no work of an artistic character requires a broader knowledge than that of landscape-gardening. Besides the creative faculty of a designer, it calls for some acquaintance with engineering, architecture, horticulture, botany, the adaptability of different plants to various climates and soils, their appearance, their rate of growth, their length of life and the social habits of the people to whom they will give pleasure. Of course, his knowledge of engineering or architecture will not be as extensive as that of men engaged in those professions, but it will be such as will enable him to bring the bridges, buildings and other constructive works into harmonious relations with the landscape.

#### The Madroña at Ukiah.

EVERYWHERE in California *Arbutus Menziesii* is known by its musical Spanish name of Madroña, pronounced with a soft "d." While found from Puget Sound to Mexico, it is in the region between San Francisco Bay and Oregon that the Madroña is at its best. Elsewhere it is oftener a shrub, here frequently a tree of considerable dimensions, specimens two or three feet in diameter being common, and one noble tree near San Rafael is said to be twenty-three feet in circumference at base.

In Ukiah Valley it is very common, extending from the dry uplands to the mountain tops, and almost exclusively covering some considerable areas on the mountain slopes. The town of Ukiah is built on a sloping upland, which was originally covered with timber, a mixed growth of Douglas Spruce, White Oak, Black Oak, Black Live Oak (*Quercus agrifolia*), Manzanita and Madroña. The founders of the town, with rather unusual good taste for pioneers, spared the native trees, and they have thrived wonderfully under the changed conditions. Trees in variety have been planted, and sidewalk trees are the rule rather than the exception. Viewed from any quarter now, the town seems hidden in a forest.

The Madroña formed a large part of the original undergrowth. A few were large trees, but there were a multitude of seedlings and many clumps of sprouts from old stubs. All have grown well, and are now beautiful and symmetrical trees, the most attractive feature of our town. Many blocks are covered with fine groves of them.

As an ornamental tree the Madroña has many virtues and a few vices. With its large elliptical leaves, suggestive of the Rhododendron, its sweet flowers in May and its glory of red berries in midwinter, it is always beautiful. No less charming are the smooth limbs left clean and shining in their rich brown coat, as the old bark sheds each summer. The leaves are shed in May and June, after the new leaves have formed. The contrast between the bright green of the new and the yellow of the old is fine, but the litter of leaf and bark is objectionable, and perhaps a little more so because the leaves do not fall as part of the general decay at the close of the year with those of deciduous trees, but at a season when all vegetation is in the full tide of life.

Ukiah, Calif.

Carl Purdy.

## Foreign Correspondence.

### London Letter.

VICTORIA REGIA.—A considerable range of variation has already been revealed under cultivation by this, the queen of Water-lilies, and two forms of it at least have been named—*Randii* and Dixon's variety. The latter is remarkable for the red tints of its flowers and for the size and depth of the rim of the leaves. A well-marked variety, new to cultivation so far as this country is concerned, is now flowering for the first time at Kew. It was raised from seeds received in January from Mr. Tricker, of the nurseries of Mr. H. A. Dreer, Philadelphia. Among its peculiarities are, first, the early cupping of the leaves, the turned-up rim being shown by quite small plants, while when full grown the leaves are large, of a lustrous bright green color, and the rim is from six to eight inches deep. The flowers produced up to the present are not quite equal in size to those of the ordinary form, but they open several hours earlier in the day and they change color earlier. Usually the sepals of *Victoria* are spinous to the tips, but in this variety they are quite glabrous. Mr. Tricker states that with him the plant grows very freely and that during the summer it is not unusual to have fifteen or twenty good leaves on a single plant, and frequently two flowers open together, a first and a second day flower. He has also had plants that flowered when in comparatively small pots and a perfect flower produced on a plant in a twelve-inch seedpan. The plant at Kew is growing along with one of the ordinary variety and one of Dixon's variety, and it is by far the strongest and most attractive in leaf characters, while it has already developed three flowers before the others have shown signs of any. It is noteworthy that these varieties of *Victoria regia* come true from seeds, so that their characters are fixed. Probably Mr. Tricker can furnish particulars of the origin of his variety.

CAMPTOSEMA PINNATUM.—This handsome stove shrub or small tree has an erect woody stem, pinnate leaves over a foot long, each leaf consisting of three pairs and one terminal ovate leaflet, ten inches by three, of a bright green color. In habit and leaf characters the plant is not unlike a young American Ash. The flowers are borne in short axillary racemes resembling those of *Erythrina caffra*, but shorter, each raceme consisting of about a dozen flowers, which are two inches long, the calyx green, mottled with purple, and the corolla rich rose, changing to rosy mauve. There is a plant of it a yard high now flowering for the first time in the Palm-house at Kew; it was raised from seeds received from Brazil nine years ago under the name of *Camptosema erythrinoides*. The genus is composed of ten species, mostly climbers, all natives of Brazil. *C. rubicundum*, a climbing species with red flowers, was in cultivation here sixty years ago, when it was figured in *The Botanical Magazine*, t. 4608, and also in *Paxton's Magazine*, where it is called a *Kennedy*. It is not known to be in cultivation now.

EULOPHIELLA PEETERSIANA.—A plant of this extraordinary Orchid has been established in Sir Trevor Lawrence's collection, where I lately saw it growing vigorously. It has made three rhizomes about nine inches long, on each of which are about a dozen leaves, each from three to four feet long and three or four inches wide, of firm, almost leathery texture and plicate. It is a most distinct-looking Orchid, undoubtedly a *Eulophiella*, a photograph of the flower showing all the characters of that genus as known in *E. Elizabethæ*. The flowering of this plant is awaited with curiosity. I am told that Monsieur Peeters, the Brussels Orchid dealer, to whom we owe the introduction of this Orchid from Madagascar, has also succeeded in establishing plants of it.

DENDROBIUM CÆLESTE.—A blue *Dendrobium* would be a decided acquisition, and if the species described under this name in *The Gardeners' Chronicle* for this week is all that it is said to be, its introduction will be awaited with considerable interest. It has been discovered in the Philippines

at an elevation of about 8,000 feet, where Oaks, Rhododendrons, Myrtles, etc., are its companions. In habit it is said to resemble *D. Victoria Reginae*, another new discovery of this year and also a native of the Philippines, described as having stems which produce "great numbers of richly dark blue and white blossoms borne in trusses and lasting in bloom for several weeks. The flowers are over an inch in diameter, the sepals and petals white at the base, with a great blue blotch at the edges, the lip ovate-oblong and of the same color." In *D. coeleste* "the fleshy flowers are entirely dark blue, with the exception of the ovary and spur, which are purple. The sepals and petals are ovate and almost equal in size, the lip obovate and blunt, the column blue." These two species are described by Mr. A. Loher, Manila.

**INCARVILLEA DELAVAYI.**—The most vigorous example I have seen of this fine Bignoniad is in the garden of Sir Trevor Lawrence, at Burford Bridge, where it is grown out-of-doors in a sunny border all summer and lifted and kept in a frame in winter. Under this treatment it develops leaves two feet long and spikes four feet high, clothed with flowers proportionately large and rich in color. According to a note in *The Garden* this plant is hardy enough to thrive if left permanently out-of-doors in most parts of England, for in Dalbeattie, near Dumfries, seeds sown two years ago have yielded plants which were in great beauty in June this year after having stood the last two winters in a climate not very suitable for tender things. It will be remembered that this plant was introduced from China by the missionary after whom it is named and that it first flowered in Paris in 1893. It is now easily obtained from the nurserymen.

**TEA ROSES AND VIOLAS.**—In a notice of Tea Roses grown by Mr. Robinson at Gravetye last year, I mentioned the excellent effects produced by planting bedding Violas (tufted Pansies) as a carpet or mulch to the rose beds. A series of beds of Teas has been planted this year bordering a curved walk against an old Yew hedge, and among these a selection of bedding Violas has been used. The effect now is most pleasing. Each bed is filled with one kind of Rose and one of Viola. There are no harsh or brilliant colors among the latter, their blues, yellows, creams, whites and piebalds harmonizing well with the whites, creams and pinks of the Tea Roses. The latter are, of course, on their own roots. It is a mistake to plant Tea Roses that have been grafted or budded. Bedding Violas are again the subject of a special trial at Chiswick, where there is now a fine collection of varieties.

## New or Little-known Plants.

### *Rhamnus occidentalis*.

THIS plant was first noticed by Mr. Thomas Howell, near Waldo, in south-western Oregon, and described by him as a shrub from two to ten feet in height, with coriaceous yellow-green elliptical leaves, from acute to obtuse or retuse at the apex, flowers in subumbellate fascicles and black obscurely lobed fruit.\* Last September I found it in the same region, but at higher elevations on the north slope of the Siskiyou Mountains, where in dry gravelly soil it forms broad compact round-topped bushes about two feet high and sometimes five or six feet in diameter, being in habit quite unlike any of the forms of *Rhamnus Purshiana*, to which it has sometimes been referred,† and from which it also differs strikingly in the yellow-orange color of the under surface of the leaves, similar to that of the leaves of *Rhamnus crocea* of southern California, a fact which has already been pointed out by Professor Greene.‡

Our figure on page 285 of this issue, made by Mr. Faxon from specimens which I gathered on the Siskiyou Moun-

tains, will perhaps call attention to this interesting plant, which on further investigation will probably be found to be specifically distinct from the very variable *Rhamnus* of the *Frangula* section of Pacific North America. The leaves are described by Mr. Howell as persistent; probably, however, they fall during the winter or in early spring with the appearance of the new growth.

C. S. S.

### An Undescribed *Antennaria* from New England.

IN the spring of 1891 Mr. J. C. Parlin collected at North Berwick, Maine, an *Antennaria* which then appeared very different from the common form, but which has not been critically studied until the present season. Early in May of this year, while botanizing with Mr. Parlin upon the intervals of Great Works River, in North Berwick, our attention was attracted by the stout, viscid, young shoots of a plant which proved to be the same as that collected six years ago. The plant was abundant in the woods or on recently cleared knolls in the interval, and, though still very young, it reminded one, upon a superficial glance, of a *Gnaphalium* rather than an *Antennaria*. At that time, early in May, the common Ladies' Tobacco, or Pussy's Toes, of the fields and meadows (*A. neglecta*, Greene, *Pittonia*, iii., 173) was in full flower, and even passing to fruit.

Later in the spring, in late May and early June, the large viscid plant has been found in great abundance by Mr. Parlin in southern Maine, and by Dr. B. L. Robinson, Mr. E. L. Rand and others in southern New Hampshire and eastern Massachusetts. The plant flowers at the same time as *Antennaria plantaginifolia* (see Professor Greene's paper); and it is interesting that, as in case of two of Professor Greene's recent north-western species, the staminate plant is unknown. Wherever found the pistillate plants have been abundant, but thus far only that form has been detected. Often, however, this species is found growing with staminate or pistillate plants of *A. plantaginifolia*.

Aside from the glandular stem and large cauline leaves and the purplish involucre, perhaps the most striking character is in the bright green smooth and shining upper surface of the strongly discolorous basal leaves. These characters separate the plant very clearly from the other *Antennarias*, and I propose it as a species, which I dedicate to its discoverer.\*

### Herbaceous Perennial Plants in Flower.

PROBABLY the finest show made by any herbaceous perennial in the garden now is the glowing mass of flowers borne by a clump of *Alströméria aurantiaca*. While this plant has flowered here annually for eight years past, at no time has it shown such luxuriance of growth and bloom as it has this season. Although it requires a slight protection in winter in this vicinity, it flowers perfectly without any protection after a mild winter like the last one. Success with this plant depends largely on the situation and the condition of the soil in which it is planted. A slightly elevated position with a warm aspect in a soil of such texture or so drained that it will

\* *Antennaria Parlinii*, n. sp. Rather tall, 1½ to 4 dm. high, the stems conspicuously leafy, pubescent with white appressed-silky or even lanate hairs, and bearing elongated purplish glandular hairs, especially toward the base and the inflorescence; stolons rather stout, glandular: old leaves of the basal rosette subcoriaceous, obovate or broadly obovate-spatulate, tapering below to a winged petiole, rounded and generally mucronate at the tip, including the petiolar base 4 to 7 cm. long in well-developed plants, 1½ to 3½ cm. wide, smooth and bright green (never arachnoid) above, almost shining in the fresh plant, 3-nerved, beneath canescent or glabrate, wrinkled and with prominent veins; lower cauline leaves spreading or ascending, oblong, obtusish, mucronate, glandular on both faces, green above, sordid beneath, 3 or 4 cm. long, the upper reduced; lower leaves of the stolons like the cauline, the terminal ones large, obovate, strikingly discolorous, bright green and smooth above, white and closely pubescent beneath: heads loosely or densely corymbose: the involucre subcampanulate, sometimes fully 1 cm. high, of 3 rows of imbricated bracts; the outer bracts herbaceous, purplish, and somewhat glandular, with short acute or bluntish erose scarious tips; the inner with the narrow scarious tips long-attenuate: styles and corollas purplish: pappus silvery white: akenes 2 mm. long, granular. In woods and on hillsides, generally in rich soil, southern Maine and New Hampshire and eastern Massachusetts. Maine, North Berwick (J. C. Parlin, 1891, J. C. Parlin and M. L. Fernald, 1897); New Hampshire, Jaffrey and Dublin (B. L. Robinson and E. L. Rand, 1897); Massachusetts, Lexington (B. L. Robinson, J. M. Greenman, etc., 1897).

\* Howell, *Pacific Coast Plants, Collection of 1887*, No. 1105; *Fl. North-western America*, 113.

† Trelease, *Gray Syn. Fl. N. Am.*, i., pt. i., 408.

‡ *Pittonia*, ii., 15.

not retain too much moisture in winter, and where the plants can be well covered with dry leaves, is the most suitable one. Another important point in cultivating *Alstromeria* is that it does not like to be disturbed too often, and therefore when once established it ought to be left alone.

sown will produce any number of young plants, and, in fact, this is the most natural and most satisfactory way of increasing the plants. My experience with the seeds is that they lie dormant one year before they germinate.

As usual, *Acanthus latifolius* is attracting much attention, as

Fig. 36.—*Rhamnus occidentalis*.—See page 284.

1. A flowering branch, natural size. 2. A fruiting branch, natural size. 3. Vertical section of a flower, enlarged. 4. A fruit laid open transversely. 5. A nutlet, enlarged.

The stems of this plant grow from three to four feet high, but they require no staking, as they are stout enough to take care of themselves. The umbels are made up of about a dozen large flowers, which are orange-red and streaked with red. An abundance of seeds are produced annually, which if

it is now in perfect flower. The plants are unusually thrifty, and there are three dozen well-developed flower-spikes now and many more which have not quite appeared above the foliage. This plant is not seen to the best advantage when grown in the mixed border. The best position is on the lawn

in an open space, where it should remain undisturbed for a number of years, and then it will compel admiration for its stately habit and foliage. This *Acanthus* is protected here in winter with a covering of leaves, but I have little doubt that well-established plants would thrive without any covering.

*Spiræa palmata* is an old Chinese plant, but one never tires of its large palmate leaves and its large clusters of rosy crimson flowers. It is slightly more than a yard high and its blossoms are carried high above the dark green foliage, which gives them a pleasing effect. *S. palmata* is probably the best herbaceous species belonging to this useful genus, and when well grown is always desirable. It does best here in a deep rich soil and slightly shaded position. It is easily increased by division either in the spring or fall.

Harvard Botanic Garden, Cambridge, Mass.

Robert Cameron.

### Notes on Pelargoniums.

**PELARGONIUMS** as known in gardens are hybrids of *P. grandiflorum*, and commonly called Lady Washington Geraniums. When properly grown they are among the brightest decorative plants we have. They are in no way delicate in constitution, and, like their near relative, the common Geranium, are sure to bloom if sufficient light and sunshine are allowed them. Pelargoniums flower during the spring months, and in order to obtain fine, shapely specimens there must be a season of preparation. Following the conditions imposed by nature, it is well to rest them until midwinter, though not to the extent required by bulbous plants; they should be watered occasionally to keep the wood firm and the roots healthy.

To begin a new collection or replace old plants, cuttings should be put in now. They take longer to root than Geraniums, and must be kept growing from the time they are rooted. Where large numbers are required, as in commercial establishments, a good plan is to plant out the old plants. They will furnish an abundance of cuttings, and the cutting-bench can be kept going until the end of September. Cuttings rooted from now onward make neat plants in six-inch pots, such as are extensively grown for the flower markets of the large cities of Europe. They have had only a limited sale as Easter plants in this country. If, however, large specimens are desired, it is better to take out the flower-buds from the young plants next spring. This strengthens them, but they must be rested to some extent, as are the older plants.

Rested plants must be repotted not later than January, gently started, stopped frequently and tied into shape. The best specimens are those trained so that the foliage and flowers almost hide the pots from view. With a light airy position and a night temperature of fifty, the plants will make good sturdy growth. Pelargoniums have a special season of bloom, unlike Geraniums, which bloom when allowed, and flower on separate growth. They cannot be retarded by taking out the flowering-stems, and when they are ready they must be allowed to bloom.

A list of some of the newest and best includes Jubilee, light pink, very attractive; Kingston Beauty, white, dark standard; Ophelia, reddish purple; Multiflora, pink, dark standard; Nellie Hayes, white, dark standard; Duke of Fyfe, pink and white; Lady Duff, scarlet and pink; May Queen, deep red; Mrs. Wright, white, scarlet tinted; Duke of York, scarlet, pink and white.

Garden Geraniums, hybrids of *Pelargonium zonale*, are more widely known. When one gardener wishes to show his contempt for another's skill, he says "he can't even grow a Geranium," which is the same as saying there is no plant so easy to grow. Geraniums are divided into bedding and fancy varieties, or such as make better pot-plants. Those of the latter class are again divided into the large round-flowered single forms, the Bicolor or Corona type, and the semidouble Bruants. Of bedding varieties it is enough to say we box off cuttings in the autumn after the first frost. They are almost sure to root if not overwatered. They may be put away on shelves, and require little attention until spring.

To grow fancy varieties into specimens requires more attention. We take cuttings at this time and keep them growing. Some few may be allowed to bloom during the winter, but those required for specimen plants may be treated as recommended for Pelargoniums. They make first-rate plants toward spring, and florists grow them in large numbers for spring sales. All that is needed is to keep the flowers picked off until within a week or two of the time when it is desired to have them bloom. Large specimens are better for being rested a month or six weeks during midwinter in a good light position with a

temperature as low as forty-five. As the days lengthen with increased sunshine they may have more water, and manure occasionally. The new growth will be covered with bloom in from four to five weeks.

Single round-flowered Geraniums worthy of recommendation are Florence Farmer, white-veined and tinted with salmon; Eleanor, clear, bright orange; Olivia, bright rose; Snowdrop, pure white; Gertrude Pearson, clear pink; Dr. S. Grey, crimson; Corona, or aureole type; Madame G. Henry, shades of rose-white and red; Madame Bruant, white, veined with carmine; Renommée Lyonnaise, scarlet, white centre; Le Rhone, rosy scarlet, white centre and white blotches on upper petals; Bruants, semidouble; Madame Janlin, deep rose; Eulalie, light salmon, an attractive flower; Gloire de France, white, pink-tinted, and Beauté Poitevine, salmon-pink.

Wellesley, Mass.

T. D. Hatfield.

### Greenhouse Notes.

**MOST** people are fond of Mignonette, especially when used with other cut flowers, and it is never at its best until cool weather or midwinter under glass. To have it early, or about Christmas, the seed should be sown at the end of this month on a bench in a house that will be cool in winter. A minimum temperature of forty-five degrees is well suited to produce good spikes, and this is about the average temperature of a Violet-house in cold weather. It is almost impossible to make the soil too rich for Mignonette, and it also does best in a deep bench with at least a foot of soil, or, better still, in what is known as a solid bed where the roots may be cool and moist. Of course, a good strain of seeds must be planted. The Machet is most generally used, but any of the selected strains are equally suitable. Care must be taken to give plenty of room when sowing. We usually sow in rows eighteen inches apart, and thin out the plants when they are of good size to six inches in the row. A close watch must be kept when the plants are young for the small green caterpillars of the white butterfly; they will speedily ruin all the seedlings if neglected for a few days, but Hellebore will help, and with hand-picking they may be kept down.

Antirrhinums are becoming popular as winter-flowering plants, and the keeping qualities of the flowers after they are cut are surprising. They make a good succession to Chrysanthemums in the benches, and will flower in early spring. To have plants suitable to set out in benches in November cuttings may be taken now from some plants whose flowers are of special colors, or seeds of the mixed varieties may be sown now to furnish plants that will not have flowered previous to planting indoors. Antirrhinums may also be grown in pots to flower, but, like most free-rooting plants, should have a bench if possible.

The newer kinds of single Violets promise to be most useful flowers. Princess de Galles is a superb flower of good round outline, very fragrant and vigorous in growth. There seems to be no tendency to disease in these new strains, at least I have detected none thus far. Luxonne is another new one that should be tried; it is not so fragrant as some others, but is the largest of all, and owing to the narrow petals it measures almost as much across as some Pansies. The color of both these Violets is a good deep blue, and there seems to be no limit to their length of stem. If grown for no other purpose they ought to be tried for furnishing leaves to go with the double varieties, as these are injured greatly from continual plucking of the foliage in winter-time.

Poinsettias are now starting freely, and as these plants repay good treatment it is well to report them as soon as growth begins. They should be placed outdoors in full sunshine for the hot months, and with the first cold nights of autumn they should be taken indoors into a cool, airy house at first. If they are wanted for Thanksgiving a little more heat will be needed. The double variety is much later in flowering, and will last well into the new year. The soil should be made very rich at potting-time by the addition of bone or some other convenient fertilizer. It is unsafe to rely upon manure-water to bring them on later, as this is sure to result in the loss of much foliage, which spoils the appearance of the plants when in bloom.

To those who have not tried it before, I would advise pinching off the flower-stems of the main crop of Carnation-plants in the field late in the season—say, the middle of August. A few plants should be reserved to flower early and set in cold frames for flowers until the end of November. They will do just as well, or better, than those planted in the greenhouse for the time, and when they are past, those in the house will be coming in with a full crop that will last all winter long, and will make a good succession to Chrysanthemums and help to

fill up the inevitable gap that always seems so hard to get over. I have frequently lifted these from the frames to take the place of Chrysanthemums on benches, and they have done well, too, but this should not be necessary. One should calculate to have no flower-spikes showing on the plants at lifting time, and then the crop will come in as described. Very large plants are by no means best, and four plants should be used to cover a given space rather than three. Unless the soil is heavy, care should be taken in lifting to get all the roots up, even if not a particle of soil adheres to them. It is surprising how well the roots take hold of the soil prepared for them if they are free of old soil and carefully planted.

Freesias should soon be shaken out of the old soil if this has not already been done. They seem to ripen better if taken out and put in a dry airy place in paper bags. They are not liable to start unexpectedly either, as sometimes happens when left to summer in the old soil in an out-of-the-way corner. We also repot Lachenalias at the same time as Freesias, and they are stored in a similar way, as they are liable to begin to root if the least moisture reaches them when at rest. Both Freesias and Lachenalias ought to be sorted as to size at potting time if well-flowered pots are desired, the small ones being set aside and grown on separately to flowering strength.

A good time to put in a crop of Hydrangea cuttings is when the strong shoots that have not flowered this summer have reached their growth. They root freely if put in a cool shady place out-of-doors, and from these plants one may get a fine truss of flowers next spring. If they are planted out for a summer they will make fine stock to grow on for forcing the year after. No plants are more likely to become too large to handle properly than Hydrangeas, and it is often a problem how to store them in fall and start them in spring. But with the rooting of a fresh lot each year useful-sized plants may always be on hand and an abundance of flowers.

If Canterbury Bells, Foxgloves, Hollyhocks and other biennials are wanted for use next year, seeds should be sown now. The plants will not be as large as those from seeds sown in spring, but will be much more useful for this reason, and will winter over better where they have to be stored, as in New England. The first two will make useful plants for early flowering in pots, and it is necessary to grow Hollyhocks each year from seeds now that the disease makes such ravages among them.

South Lancaster, Mass.

E. O. Orpet.

### *Ipomœa pandurata.*

SOME of the tuberous-rooted *Ipomœas* have been in bloom in the open border here for some time past. They make a very attractive display, and when compared with other summer-flowering exotic plants, in return for very little attention given them. Among the most interesting of these are two native species—*I. pandurata* and *I. Michauxii*. The latter comes from the southern states, and needs a thick covering of leaves or some such material over the crowns to help it withstand severe weather. Even then, if kept out, it is usually late in starting, and the summer is nearly gone before it comes into bloom. By allowing the shoots to get several feet long in the greenhouse before planting out, which they will do even when the tuber is not placed in soil, but merely allowed to lie under the staging, the season of blooming is hastened very much.

*Ipomœa pandurata*, known commonly as "Man of the Earth," owing to the immense fleshy roots of the full-grown plant, is a native of the eastern states, and is common from Connecticut to Georgia on sandy banks and neglected farmlands. As showing the size of the underground portion of the plant, some years ago I spent two hours with pick and spade in digging up an old plant. The root measured more than three and a half feet long, and at the thickest part ten inches in diameter. This plant has since produced hundreds of its showy flowers every summer, and is yearly covering more space. It is growing in a mixture of sand and vegetable humus, and every autumn it gets a good covering of manure, not as a protection, but to enrich the soil. There are at least two forms of *I. pandurata* found in a wild state; one has flowers about two and a half inches across, the other has flowers twice this size. The merits of this species must be judged from the way specimens grow in their native wilds. As we usually see them they have very few long straggling stems and comparatively few flowers expanded at one time. When brought under cultivation—that is, when full-grown specimens are transplanted—the plant throws out a great number of stems and flowers from the beginning of June till September. Under cultivation, however, the flowers are no larger than they

are in a wild state. The propagation of the plant from cuttings I have found to be by no means easy; in fact, it seems to be quite as difficult to root as the well-known tropical species, *I. Horsfalliæ*. The roots of medium-sized plants, when cut into pieces about three or four inches long, will occasionally sprout, but this is by no means a certain method, as they have been known to remain in an inactive condition for more than a year. Where old plants are growing wild in a well-drained soil they seed freely, and young plants are quickly raised from them. Seedlings, however, take a long time to make good flowering specimens. Any of the tender tuberous-rooted species, which are found to be difficult to root from cuttings, will be found to take readily when grafted on pieces of the root of *I. pandurata*. The operation should be performed in late summer, when the shoots are thoroughly ripened.

Botanic Garden, Washington, D. C.

G. W. Oliver.

### Notes on Carnations.

PLANTS out-of-doors are looking extremely well this season. We have not yet had any prolonged drought, as is common in July and August, and young plants are all growing luxuriantly. The first ten days of July were exceptionally hot and dry, but by keeping the ground well stirred the plants did not seem to suffer in the least, and a copious rainfall on the 13th, with continued high temperature, started them into active growth. Success next winter depends largely on the treatment given the plants from now until lifting time in September. If the ground is allowed to bake and weeds to grow, only failure can be expected. Whether watering ought to be resorted to in dry weather is a debatable question. Many successful cultivators condemn it altogether, and personally I am not in favor of it unless it can be done thoroughly. In commercial establishments, where many thousands of plants are grown, watering would be expensive in many cases, and in others impossible, owing to deficient water supplies. On private places, where at most a few hundred plants are housed, artificial watering can be done quite readily if a good length of hose and a standing sprinkler are at hand, by having the sprinkler at work in one place for two or three hours, when a bed will be pretty thoroughly soaked. Many artificial aids to growth are needed in our climate, and I approve of watering when plants show signs of suffering rather than wait for a chance shower. Plants allowed to become dust-dry at the root and to droop helplessly will certainly not give as satisfactory returns as those kept growing steadily. After every watering and rainfall a thorough cultivating of the soil among the plants is necessary. Weeds grow apace at this season, and many of them will need rooting out by hand if they are close to the plants. Once a week we go over the rows and do any stopping required, holding the shoot with one hand and drawing out the top with the other. A mere nipping or clipping off of the tops is of no use whatever.

Summer-blooming Carnation plants are now flowering quite freely. The earliest and best sorts are Daybreak, Mrs. Fisher and some unnamed scarlet seedlings. A scattering of some chemical fertilizer, such as Bowker's Hill and Drill Phosphate, or sheep-manure, or a soaking of liquid manure after a heavy rainfall, is beneficial. Heavy rains dash the soil on the flowers if the plants are not kept well tied up, and we find a light mulching of spent mushroom-manure, or any old manure, helps to keep them clean and the ground moist. There is, as a rule, not much time for disbudding Carnations during the hot summer months, but if this can be done improved flowers and stiffer stems will be had. Our hot, dry summers and severe winters make it impossible to successfully grow the border Carnations which are the glory of English gardens at this season. But by a selection of suitable American kinds any garden may show a constant succession of bloom from early in July until sharp frost cuts down the plants. The Rose is undoubtedly the queen of flowers while in season, so far as outdoor ones are concerned, but three weeks is about the term of the Rose season, and after that only an occasional bud is to be seen. It is not strange that Carnations are the flowers of the million, for their fragrance, freedom of bloom and lasting qualities all recommend them. Cut sweet peas or roses in an ordinary living-room last only about forty-eight hours, while a vase of Carnations will keep fresh for nearly a week.

Many growers throw out their Carnation plants from the benches before hot weather sets in. We generally keep ours in until September 1st, just allowing time to clean out the old materials and prepare for the winter stock. The benches should have a coat of limewash and be retiled and the new stock planted. Plants thus furnish flowers for nearly twelve

months. Our plants were given a mulching of cow manure in May and a soaking of some liquid stimulant once a week during the summer months, and a thorough hoeing early in the afternoon of every clear day to keep red spider in check. The most persistent bloomers are mainly well-tried varieties, such as Lizzie McGowan, William Scott, Thomas Cartledge, F. Mangold, Eldorado and Alaska. The most unsatisfactory sorts include Meteor, Bridesmaid, Helen Keller, Triumph, Crystal and Nicholson.

Attention should now be given to the compost-heap intended for use in the benches in September. Too often these heaps are a mass of rank weeds which take up a large part of the food intended for the Carnations. We always use some bone-dust in compost, and if this has not yet been added it should be mixed in now. Weeds should be kept out of the heap by all means, and a few minutes' work once a fortnight will suffice to accomplish this.

Taunton, Mass.

W. N. Craig.

**For Winter Flowers.**—Among border plants useful for furnishing cut flowers in winter may be mentioned Snapdragons. We have selected varieties propagated from cuttings, and some strains come tolerably true from seed. In a white-flowered collection was one with the delightful odor of orange blossoms. *Coreopsis Drummondii* is another useful plant and furnishes enormous quantities of flowers. The seeds should be sown now to secure good plants for autumn-blooming. *Anthemis tinctoria* will replace yellow Marguerites, and this also makes neat little pot plants which flower nicely in five-inch pots.

Wellesley, Mass.

## Correspondence.

### The Sycamore Blight.

To the Editor of GARDEN AND FOREST:

Sir,—I never chanced to observe the Sycamore blight on an Oriental Plane-tree, and we have always had the impression that it was free from the disease, or, at least, so rarely attacked that we have never hesitated to recommend its use. The disease is so virulent this year that I should be glad to have reports from your readers who observe Oriental Plane-trees. I have noticed that on our native Sycamores the young trees are not generally affected, and I am curious to know the reason of their immunity. The blight is very common in the New England states, and, as far as my observation goes, it becomes less frequent as one goes south. In former years I have looked in vain in North Carolina for a tree which shows the characteristic bunchy growth of twigs caused by the disease. If the fungus is not limited by climatic conditions our Sycamore is a doomed tree for landscape purposes in all parts of our country.

Brookline, Mass.

F. L. Olmsted, Jr.

[Professor W. R. Lazenby writes in the current issue of *The Country Gentleman* from Nashville, where he has been attending the Exposition, that the blighting of the leaves of our native Sycamore is such a universal occurrence this year wherever he has traveled, that an uninfected Sycamore-tree is a rarity. Professor B. T. Galloway, chief of the Division of Vegetable Pathology in the Department of Agriculture, writes that *Platanus orientalis* is affected by the blight in Washington as well as the native species, although not as severely, and he adds that neither of the trees is as badly diseased in that city as they have been in former years. Dr. Halsted says that, while he has never observed this anthracnose upon the Oriental Sycamore, this tree is known to be a host of the fungus, and the blight was first described in Europe upon *Platanus orientalis*. The same *Glaesporium* also occurs on *P. racemosa* in California.—Ed.]

## Notes on Hardy Plants.

To the Editor of GARDEN AND FOREST:

Sir,—The beautiful *Campanula persicifolia* has developed an interesting peculiarity which I have not seen recorded and which I have not noticed in any other herbaceous perennial. It is always my custom to cut away the flowering stems of herbaceous perennials when through blooming. In this instance, however, they were left on to obtain seed. The old flowers are now dried up and seed-pods have formed, yet between each of the former flowers new buds are forming and open-

ing on the old stems all the way from bottom to top. It remains to be seen how many times this process will be repeated during the season.

*Cimicifuga racemosa* is a desirable subject for the garden in a moist spot where it will get the morning sun. The shape of the plant is very graceful, and the long, twisted panicles of fine white flowers at the top of the long branches are extremely decorative. The fragrance is almost oppressive and the bees swarm among the flowers.

*Pentstemon barbatus Torreyi* is seldom seen in gardens, but is remarkably handsome when well grown. This season has been especially favorable to its needs, and the stems have been from three to four feet long, covered from tip to about a foot from the ground with showy vermilion drooping flowers. It stands the winter well and increases in size.

Bergen Point, N. J.

L. C. L. Jordan.

## Flowery Byways.

To the Editor of GARDEN AND FOREST:

Sir,—Our native trees, shrubs and vines about St. Louis and in southern central Illinois have flowered with unusual profusion this year. First, the wood borders in all the ravines and bluffs on the Illinois side of the Mississippi blushed with the opening flowers of the Red-bud trees, and on the Missouri side the wild native growth on the tongue of lowland between the big rivers for miles above their confluence was rosy with the blossoms of the same trees. Following these were Dogwoods, Wild Plums, Cherries and Crab Apples, and later on every woodland way was powdered with the stars of Wild Blackberry blossoms, and the air was fragrant with the flowers of the Wild Grape from vines that were clambering over the trees. After these came in lavish abundance the blossoms of *Cornus paniculata*, with mounds of Wild Roses piled over the fences or over each other, and just now the course of every stream is outlined and every fence corner is decorated with the immense cymes of creamy Elder blossoms, the commonest and yet one of the most beautiful of our native shrubs, while along the railroad rights of way the posts of the barbed-wire fences stand like many-branched candelabra supporting the flaming flowers of the Trumpet Creeper.

Brighton, Ill.

Fanny Copley Seavey.

## The Cost of City Parks.

To the Editor of GARDEN AND FOREST:

Sir,—Your editorial, entitled "One Way to Reduce the Cost of Park Maintenance," suggests the thought that in many great industrial centres park accommodation is entirely inadequate. We have one great park on Manhattan Island and a number of smaller parks, but our congested population needs many more open spaces in which the free sunlight and the breath of nature can have full sway, and we must have them before this city assumes its proper place in the march of progress.

One great difficulty in the way of establishing parks in great centres of population is the opposition of landowners. Of course, in condemnation proceedings, the ousted owners naturally interpose objections, even if to be paid the full value of the condemned property; but such objections generally indicate a disposition to drive a hard bargain with the community, and need scarcely be regarded seriously.

With respect to other owners, if it can be shown that taxpayers not only do not suffer loss, but that the outlays necessary for park extension are borne in the majority of cases by the rent-paying public, little opposition might be expected to the extension on a large scale of a class of improvement that peculiarly reflects advancing modern civilization.

As a matter of fact, proven by the history of all such improvements, the cost of opening and maintaining parks, where sites have been judiciously selected, is in the nature of an investment from which large returns can be confidently expected. While the shortsighted policy of some property owners will always stand in the way, the opposition from this source can be reduced to a minimum by the educational influence of periodicals like GARDEN AND FOREST. A public-spirited press can do much to advance the public interests when threatened by the fatuous opposition of people blind to their own.

Much of the opposition has arisen from the unscientific methods of assessing the cost of parks, the usual plan being to charge one-half against the immediately abutting properties and the balance on other taxpayers through general taxation. This plan, which arbitrarily allocates a great part of the expense without taking into account all the property benefited,

necessarily works injustice, and those owners likely to suffer loss will make a more vigorous fight against improvement than its friends will in its favor. For instance, it can be readily seen that while residential properties adjoining a new park might increase in rent-yielding value to the full measure of their assessments, properties devoted to business could derive no advantage. On the contrary, because of the increased capital charge, business in the improved locality would have to be conducted on a less profitable basis or move away. Cases of hardship cannot be altogether avoided under any scheme of municipal improvement, but substantial justice can be done under a fair system of assessment. Park improvements will radiate value over a much greater area than the immediately adjoining properties. For example, Central Park undoubtedly diffuses a value throughout the whole of Manhattan Island, though, of course, in greater degree as the properties affected lie in its near vicinity.

Assuming, therefore, that park property is a paying investment, it remains to be seen what class of property ought to bear the cost. In this connection it may be pointed out that real estate reaps the whole benefit in a financial way, but, it may be observed, improvements on real estate do not reap a corresponding benefit, although these serve as a vehicle to convey the accruing increase in value to the owners in the tangible form of rent. Nothing of the kind can increase the value of improvements beyond the cost of duplication.

It would seem to follow, therefore, that the scientific method of charging the cost of parks is by a general tax on values of real estate, without respect to the improvements thereon. Such a method would obviate the greatest difficulties attending the opening of new parks, and, because distributed among all the taxpayers in the exact ratio of benefits received, would provide for their maintenance on a liberal scale without unnecessary friction.

New York.

### Recent Publications.

Another part of the *Synoptical Flora of North America*, being vol. i., part i., fascicle ii., embracing the orders of Polypetalæ from Caryophyllaceæ to Polygalaceæ, has recently appeared, having been issued on June 10th last. The first part of this work, upon which Asa Gray labored assiduously for many years, appeared in 1878, being devoted to the Gamopetalæ after Compositæ. In 1884 Professor Gray produced another part, including Caprifoliaceæ to Compositæ inclusive, the elaboration of the last family being his most important contribution to descriptive botany. After his death the work was taken up by his successor, Mr. Sereno Watson, who died, however, without adding to it. In October, 1895, Dr. B. L. Robinson, curator of the Gray Herbarium, issued vol. i., part i., fascicle i., including the families beginning with the Ranunculaceæ and ending at Frankeniaceæ, and he now issues another part which is a substantial addition to this important work.

The great Pink family, occupying nearly fifty pages, has been elaborated by Dr. Robinson himself, who also contributes monographs on the Ficoideæ, and has also arranged and extended Dr. Gray's preliminary studies on Portulacaceæ, Elatinaceæ, Malvaceæ, Tilliaceæ, Zygophyllaceæ, Rutaceæ, Burseraceæ, Anacardiaceæ, Cyrtillaceæ, Olacineæ. The account of the Sapindaceæ and Polygalaceæ is also from Dr. Robinson's pen, while Professor Trelease describes the Linaceæ, Geraniaceæ, Celastraceæ and Rhamnaceæ, Professor Bailey the Vitaceæ, and Professor Coulter the Hypericaceæ.

The form of the work is similar to that adopted by Professor Gray, and the nomenclature and arrangement of the families and genera are as they were when he died. This part contains, we believe, the last of Professor Gray's manuscript, so that the succeeding parts will be entirely the work of his successors. It is most desirable that they appear as rapidly as possible, for a complete Flora of North America is sadly needed everywhere by the students of botany.

We notice that especial attention is now given in this work to the correct citation of bibliographical references and figures, although the plates of different species of *Hypericum* which have appeared from time to time in the columns of this journal have been overlooked, while in

other families, as far as we have observed, the figures of GARDEN AND FOREST have been cited. As must invariably happen where work of this sort is done by different authors, there is a certain unevenness of treatment, although Dr. Robinson's careful editing has largely remedied this inconvenience.

It is not our purpose here to criticise the system of nomenclature adopted in the *Flora of North America* or to discuss questions of the limitation of species, but simply to call attention to the appearance of this important contribution to the knowledge of American plants and to congratulate the editor and his associates upon the completion of a thoroughly conscientious, conservative and able piece of work, which we hope soon to see followed by the concluding parts of this work, the best and greatest monument of Asa Gray.

No. 2 of vol. v. of the *Contributions to the United States National Herbarium* is devoted to a most interesting account of the plants used by the Klamath Indians of Oregon, by Dr. Frederick V. Coville, the principal botanist of the Department of Agriculture. Nearly all the trees of the region were used by the Indians in one form or another. The bark of the White Fir, *Abies concolor*, to dye and tan their buckskin; the wood of *Juniperus occidentalis* for boys' bows; the wood of *Libocedrus*, which is rare in the region west of the Cascade summits, in former times for fire blocks and occasionally in basket-making, the branches and twigs of this tree being frequently employed in administering sweat baths to the sick. The seeds of the Sugar Pine were used for food, while from the Lodge Pole Pine, *Pinus contorta*, var. *Murrayana*, sections of the bark are cut for baskets for gathering berries, particularly huckleberries, which, placed in such receptacles and covered with leaves, retain their freshness for a long time. The pitch from this tree is used as a remedy for sore eyes, a small fragment being placed inside the lid. The young stems, stripped of their bark, are used to push dug-outs through shallow water. The cambium layer was scraped off and eaten in time of famine just as the bark of the Yellow Pine was used, a fact which was noticed long ago by Dr. Lyall, the naturalist of the Oregon Boundary Commission.

The chief timber used by the Klamaths is derived from the Yellow Pine, *Pinus ponderosa*, the common tree in all the region east of the Cascades. Their dug-outs are made from single logs of this tree hollowed out by fire, and its twigs were used as kindling-sticks in producing fire by friction. From the Yew, *Taxus brevifolia*, which is pretty widely distributed over all the mountain ranges of the north-west, was derived the favorite bow wood of all the Indian tribes of that part of the country. Hats were made from the bark of *Populus tremuloides*, and cloth from that of *Populus balsamifera*. The frames of the Indian snowshoes are commonly made from Willow wood, and the young shoots of the different Willows which abound in the region are used as material for packing-baskets. The bark of the Alder, *Alnus tenuifolia*, boiled in water, formerly served as a dye.

It is curious to note that the Indians who were forced to eat the roots, fruit and seeds of almost every plant, made no use of the berries of *Berberis repens*, which certainly are less disagreeable to the taste than many of the things they seemed to relish. *Philadelphus Lewisii*, the common Syringa of the north-west, it appears, has obtained the name of arrow-wood because the Indians used the stems in the manufacture of large arrows for war purposes or the killing of big game.

This is one of the most important and interesting contributions to economic botany which has appeared for a long time, and it will be followed, we trust, by similar studies of the plants of other regions.

### Notes.

A correspondent of an English paper speaks of the La Mance Iris as the best garden Iris among the North American species. The flowers are large and of a singularly rich color, the

light green styles being a noticeable feature which is considered to add to the beauty of the plant as well as to its distinctness.

A Wellesley, Massachusetts, correspondent writes with enthusiasm of a specimen of *Brassia verrucosa* in the collection of Mrs. Durant. It has twenty well-formed spikes.

The strawberry crop in Kent, England, this year has been quite phenomenal, according to the *Westminster Gazette*. In one day thirty tons were sent from Sandwich alone.

At the late National Rose Show in England the first prize for a dozen trusses of hybrid Tea Roses in not fewer than nine varieties was taken by Messrs. D. Prior & Son, who exhibited *Marquise de Litta*, *Caroline Testout*, *Kaiserin A. Victoria*, *La France*, *Captain Christy*, *Mrs. W. J. Grant*, *White Lady*, *Lady Mary Fitzwilliam*, *La Fraicheur* and *Auguste Guinoisseau*.

During the last six years the number of public parks in Glasgow have been more than doubled. And although it has been complained hitherto that the corporation has favored the well-to-do west end and neglected the industrial east end in regard to open spaces, it has now purchased for \$150,000 one of the most picturesque spots in the neighborhood of Glasgow, just on the eastern boundary of the city.

The hybrid between *Rosa multiflora* and General Jacquemint, which has been named the Dawson Rose, after its originator, is spoken of very highly by English connoisseurs, and, according to *The Garden*, it is one of the very earliest Roses to bloom there out-of-doors. This year it was in good flower on the 28th of May. It seems to have retained its free-flowering habit across the sea, where it has proved one of the most floriferous and showy of pillar Roses.

Among the curious wares for sale on the push-carts of the east side of this city are Cassia-pods, which come from northern Africa. These pods are the fruit of *Cassia Fistula*, the Pudding Pipe tree, a native of India. The pods are from one to two feet long, cylindrical, dark brown, with a woody covering and divided into compartments, each containing a flat seed surrounded by a dark pulp, which is the edible portion. This pulp is sweetish and is said to have laxative qualities.

The *Kœlreuteria*-tree has been known in European gardens for more than a century, and it is not rare in the parks and gardens of this country. Like many eastern Asia trees, it is occasionally disfigured by that mysterious "die-back" which shows itself in the death of single branches without any apparent cause. Owing, perhaps, to the abundance of moisture this year, the pinnate foliage has been unusually abundant, appearing in airy and almost Fern-like masses. Just now the trees about here are coming into flower, and the large terminal, spreading clusters of clear yellow flowers at this season, when no other trees are in bloom, make the *Kœlreuteria* a conspicuous object. These flowers are succeeded by bladdery fruits, which are also interesting.

*Rosa setigera*, the beautiful native climbing Rose, has just passed out of bloom, and although its merits are beginning to be appreciated, we never feel that we can say too much in its favor. In the very first volume of this journal we spoke of the freshness of its broad, clean, healthy leaves and of the conspicuous beauty of its great corymbs of large, deep rose-colored flowers. But there was little demand for single Roses, especially of the native kinds, and it is only within recent years that nurserymen have kept it for sale. It is perfectly hardy and will make strong shoots fifteen feet long in a year, which may be either trained to some support or left to arch over on the turf or trail down a bank. When a stem is cut the flowers keep opening in succession, so that they last a long time. In the autumn its stems turn to a dark purple and the leaves to a brilliant orange and scarlet. In the Arnold Arboretum and in the Boston parks generally, where the *Prairie Rose* has been largely planted, it has been better than ever this year, and many good judges are inclined to class it in the very foremost rank among useful shrubs.

President T. S. Gold, of the Connecticut Board of Agriculture, writes to *The American Agriculturist* that an experience with more than one hundred varieties of grafted Apple-trees convinces him that the stock has no influence on the taste of the fruit. That is, if a very sweet apple is grafted on an exceedingly sour stock the sweetness of the resulting fruit is not reduced. The acidity and other qualities of apples are largely affected, however, by the health of the tree and its location, some varieties varying much more than others. For example, the Northern Spy and the Yellow Bellflower vary from the best to the most worthless fruit. On one tree apples may be tender, juicy and of a pleasant acid flavor, on another they are

tough, corky and acid, without any suggestion of sweetness. When a tree has been long in grass, producing sour and worthless apples, a cartload of strawy manure spread about the trunk opens the turf, starts the growth of the tree and gives to the fruit the richest flavor. Spraying with Bordeaux mixture, which protects the foliage from disease, has the same good effect on the fruit.

In a long letter to *The Rural New-Yorker*, a correspondent from the Mississippi Valley gives some interesting stories of the manner of life in that region during the time of the great deluge. Some people, who had already made their gardens before the flood came, took the precaution, as the rising water became more threatening, to nail a plank around the sides of the back galleries of their houses and covered the floor with several inches of earth. The vegetables were then lifted from the garden and planted in this soil, and in this way most of the growing plants were saved until the water soaked into the ground and the plants could be set back in their places. These persons were able to show thrifty vegetables a few days after the water had disappeared when their neighbors were getting ready to sow their seed again. It was the orchards, however, which suffered most. Several weeks of standing water will kill most trees, and the Peach-trees were the first to wilt and die. About the only fruit-trees which seem able to endure three or four weeks with their roots in water are the hardy varieties of the Plum, and for this reason it is recommended that hereafter Peaches in districts liable to be flooded shall be grafted on Plum stock.

Although the season for berries is waning, all the kinds are still represented in our markets, as strawberries, red, white and black raspberries, wild blackberries from Delaware and Maryland, and Wilson, Kittatinny and other popular cultivated kinds, huckleberries from the Shawangunk and Pocono mountains and other near-by sections, large luscious red currants, immense English gooseberries, ripe, and intended to be eaten out of hand. Besides the supplies from Delaware, Maryland, New Jersey and Pennsylvania, trains of refrigerator cars arrive here daily from the berry-growing section of New York state, about Oswego, Rome, etc. From the *Fruit Trade Journal* it is learned that these trains consist of sixteen to twenty-two cars, and each contains about two hundred crates. The cars are on the way only from ten to fifteen hours, so that the berries come through in first-class condition. All these state berries are received at the freight depot which stands upon the site of the old St. John's Park, and every morning during the season that locality is crowded with wagons and trucks which convey the consigned fruit to small dealers, commission houses, hotels and steamboat companies. The height of the season for these fruits was reached on June 25th, 26th and 27th. For the week ending July 6th ninety-eight carloads of berries, or nearly 20,000 crates, came from the Oswego district alone. The berry crop in western New York has been unusually good this year, so that with favorable rates fixed by the railroad companies, the season has been a profitable one to the growers. Wild Goose plums and cherries, from near-by states, are fairly abundant, and Moore's Early grapes, from South Carolina, are seen. Le Conte pears come from the south, and besides new apples from Delaware, Maryland and Virginia, there are early varieties from the orchards of this state and New Jersey. Sound hand-picked apples sell for \$3.50 a barrel. Altogether, 115 carloads of watermelons were received here last week by rail and steamer, from South Carolina and southward. The best grades are entrusted to rapid carriage by rail. The spicy Jenny Lind and Gem and the red-fleshed Christina melons come from the Carolinas and Virginia, but many shipments are of inferior quality, and choice muskmelons are scarce. The quality of Georgia peaches continues unsatisfactory, as much of this fruit is stung and has been bruised in falling, and the sound hand-picked fruit has too often been gathered green. Among the best kinds now coming from Georgia are Elbertas; from South Carolina, Mountain Rose, and from North Carolina, Tillotson. A few early peaches are already received from Maryland and Delaware, but these hardly suggest the mature fruit which will be seen a few weeks hence. But a short note cannot include more than mention of some of the fruits bought and sold in any large American city at this time of year, for, besides the near-at-hand products already named as reaching this city last week, there were some 80,000 bunches of bananas, 50,000 cocoanuts in one cargo alone, nearly 500 barrels of pineapples from Cuba and several thousand crates of the same fruit from Florida, nearly 75,000 boxes of Mediterranean lemons, besides sixty-three carloads of pears, plums, peaches, apples and apricots from California.

The Administration of the Forest Reserves.

THE Hon. Binger Hermann, Commissioner of the General Land Office of the Department of the Interior, has lately issued a circular of rules and regulations for the government of the forest reserves. These rules are approved by Secretary Bliss, and they are promulgated in accordance with the amendment to the Sundry Civil Bill, which was approved June 4th, and which authorizes the Secretary to establish such a service and to prescribe such rules as will insure the objects for which the reservations are created.

Many of these rules are in a line with the scheme of administration advised by the Committee of the Academy of Sciences, while others directly contravene the principles there laid down. At the outset, however, it may as well be said that the character of the rules published by the Secretary is not a matter of serious practical moment. He has not the machinery nor the money to enforce them. Many of his predecessors have been earnest in their desire to check timber depredations on the public lands, to mitigate the dangers to the forest from fire, and to protect the mountain slopes from the pasturage of hoofed animals which destroy the forests wherever they tread. Like his predecessors, Mr. Bliss will be compelled to rely upon employees appointed for political reasons, and many of them in full sympathy with herders and speculators and prospectors and timber thieves who have had their way unchecked ever since they drifted into the west. Indeed, these men have always been allowed to use the forests as if they owned them in fee simple, and they naturally resent any attempt to restrain them by federal interference as an infringement upon their rights—rights which they feel that they have acquired by long usage, even if they do not rest on definite statutes. There have always been rules and regulations enough to protect the property of the United States, but, of course, the rules are not able to enforce themselves, and naturally no great energy has been expended in their enforcement when this work has been entrusted to political appointees, often selected from the districts which they are to oversee. It is true that cases are brought to trial, but no one expects local courts

and juries to take the matter seriously, so that attempts to enforce the laws have been farcical. Rules have not yet been able to prevent individuals or corporations from cutting timber wherever they choose on some pretext or other, or from selling it in a distant market, whenever this could be made profitable. They have not prevented sheep from following each other up steep mountain slopes in long procession and trampling out ditches to facilitate the gathering of floods to lay waste the plains below. They have not prevented flocks and herds from gnawing every green thing to the ground—grass, herb, shrub and seedling trees—so that the snows will melt more quickly. They have not prevented herders from burning over league after league of mountain slopes to furnish fresh herbage for their flocks in spring and insure the desolation of the lowlands by floods, and the filling up of agricultural intervals with debris from the mountains.

It may be said here that a portion of the forest property owned by the nation has been to a certain extent exempt from these ravages. Nothing can arrest a forest fire when it has gathered full force and is sweeping through the dry and resinous woods of the distant west. But there is such a thing as preventing fires and checking them at the outset. Ever since the Yellowstone National Park has been patrolled by a troop of United States cavalry that vast territory has suffered comparatively little in this respect. There are three national parks in California, and while the surrounding forests have been imperiled by sheep-herders, a small detachment of United States troops have sufficed to avert the danger. These object-lessons and similar ones in Canada and other countries so plainly indicate the proper way to preserve our forests from its worst enemies that we can only express regret that the first bill recommended by the National Forestry Committee has not already been passed at the extra session of Congress. This bill provided that the Secretary of War should be directed, upon the request of the Secretary of the Interior, to detail troops to protect the forests, timber and undergrowth on the public reservations and on the national parks until a permanent forest bureau has been authorized and organized.

It is no fault of the Secretary of the Interior that he cannot call upon the army with the assurance of any assistance under existing laws. It is no fault of his that the construction of roads in the reservations is authorized, although with the force and information at his command this will mean that any one who wants a road will get it where he likes, and every time one of these roads is built it means new danger from fire over a large territory. The Secretary must make regulations for the location of mines and the procuring of timber for certain uses; but without any force at his command to compel obedience to his restrictions, this means that anybody can procure timber and locate mines and do generally what he likes. Section 13, however, seems to us distinctly a step backward. If we understand it, the pasturing of cattle is permitted in all reservations, and sheep are allowed to range in the states of Oregon and Washington, although they are shut out from other reservations. This exception is made in favor of the extreme north-western states because "the continuous moisture and abundant rainfall of the Cascade and Pacific coast ranges make rapid renewal of herbage and undergrowth possible." Now, the fact is that the eastern slopes of the Cascade range, and all the ranges of eastern Washington and Oregon, are arid, and these are the places where sheep are most abundantly herded. On the other hand, where the undergrowth is luxurious, there is an additional temptation for the shepherds to fire it in order to get it out of the way. This regulation is made against the experience of all other countries where domestic animals have ever been allowed to browse in the forests, and it is contrary to the expressed judgment of the National Academy, which is the scientific adviser of the Government and the body authorized to give counsel in such cases. The situation is this: One Secretary of the Interior asked advice of the National Academy, and the National Academy distinctly

states that sheep-herding should be forbidden in all the national forests. In the face of this the Administration permits it in two states, and thus takes the responsibility of endangering the interests of large communities. Nobody knows what sort of pressure has been brought by these two states to exempt them from restrictions imposed upon other reservations, but certainly the pasturage of these great ranges, although it may help to enrich a few individuals, is against the highest welfare of the people of the United States, who own these lands and the forests on them.

### The Douglas Spruce.

THE illustration on page 295 of this issue gives a far better idea of the dimensions attained by this tree than any mere enumeration of diameter measurements. In the region adjacent to Puget Sound, where the logs represented in our illustration were cut, the Douglas Spruce, *Pseudotsuga taxifolia*, grows to its largest size, often attaining a diameter of ten feet above the swell at the base of the trunk. Trunks twelve feet in diameter are reported, but if they exist they are very rare, trees with stems five or six feet in diameter representing an average good forest growth. The maximum height which this tree attains is still doubtful, and we shall be glad of any facts regarding it. It is probable that some specimens near Puget Sound have grown three hundred feet high, and there are stories, still needing confirmation, of individuals four and even five hundred feet in height. So far as we know, however, the tallest North American tree of which there are reliable measurements is the Redwood, measured last year on Eel River, California, by Professor Sargent, General Abbot and Mr. John Muir (see vol. x., p. 42), which was three hundred and forty feet in height.

### The Effects of Wind on Trees.

THE great tornado of May 27th, 1896, gave an opportunity rarely offered for observing the effects of a strong wind on different trees. Professor J. B. S. Norton, botanical assistant in the Missouri Botanic Garden, took abundant notes at the time and has watched the trees during the past winter and marked their growth this spring. The results of these observations were embodied in an interesting paper read before the St. Louis Academy of Science, the chief portions of which we take pleasure in presenting to our readers through the kindness of Professor Norton:

The general effects of wind on trees play no very important part in the economy of nature. The action of varying winds on trees calls forth the efforts of the trees to strengthen the wood in every direction, so that trees growing in exposed situations are stronger and consequently make better lumber. The only thing to keep whole forests from being overthrown where the trees are crowded together is the protection afforded by the more sturdy ones on the border. In localities where there is a prevailing wind the trees lean in the opposite direction, as is noticeable along the seacoast, where they seem to grow away from the water. Mr. Eigen, in *Zoe*, April, 1892, says that, besides causing the phenomenon just mentioned, the wind plays a prominent part in determining the shape of the tree. Most trees in wind-swept places have horizontal crowns. Some of these may grow more erect when transplanted to other situations. One species of *Baccharis* on the coast of California, with a spreading top, changes its shape so much when grown in the mountain regions away from the wind that the mountain form has been described as a different species. Other species that have grown for ages in windy situations may have the horizontal shape so fixed that it is retained wherever they may be grown.

In looking over the trees about St. Louis most of my observations have been confined to the western part of the city near the Missouri Botanical Garden and Tower Grove Park, where the damage was done by a straight wind from a westerly direction. This is shown even now by the fact that most of the branches removed were from the west side of the trees, where they were bent more by the wind, those on the opposite side being under but little transverse strain. A great

many trees that were partially uprooted are still inclined more or less toward the east. A few trees that were strained beyond the limit of the elasticity of their trunks, and yet did not break, still retain the curve away from the wind. This can be seen in a few *Taxodiums* in the garden and in many Elms about the city, perhaps in other trees. In Lafayette Park, where the genuine tornado did its work, the conditions are quite different and the destruction much greater, but many things besides wind must be taken into account as causes of the effects observed. Soil conditions have much to do with the uprooting of trees, as also does the root-form. Trees like the Spruce, with spreading roots near the surface, will be much more easily uprooted than those with tap-roots. If the root system and the soil which surrounds it is able to stand more strain than the parts of the tree above ground a break in the trunk or branches will result. The breaking depends on the strength of the wood, the amount of surface exposed to the wind by branches and foliage, and to a great measure on the shape and position of the tree and the method of branching. Conical trees like the Sweet Gums, European Elms and most of the conifers would have less strain on the roots and trunk than those of the opposite shape like American Elms, and Maples. The latter have the most of the wind-exposed surface toward the top where the wind is stronger, and the additional force and weight so far from the base gives a greater leverage on the roots and trunk. So we should expect more of the spreading-topped trees to be broken or uprooted, and such is the fact. But the breaking or splitting of so many trees of this form is to be attributed more to their method of branching. Trees with excurrent trunks and small lateral branches are not nearly as apt to be broken as those with a number of large ascending branches. Trees of great elasticity would be injured less than those not so elastic. The Silver Maples suffered as they did probably on account of their brittle wood, not being able to give before the wind without breaking, like some more elastic woods.

The damage would have been much less had the tornado made its appearance when the trees were leafless. Taking all the wind storms together, the coniferous trees are probably injured more than others for the reason that they always have a heavy load of leaves and because most of the wind storms come when the deciduous trees are leafless. The leaves offer a much greater surface for the wind to play upon, and especially do wet leaves, as has been pointed out by Mr. Kerr in the Proceedings of the Staten Island Natural Science Association for March, 1895. Where the leaves are not matted together by the water in rain storms, as they probably were in the St. Louis tornado, and thus offer more weight and resisting surface to the wind, it is interesting to notice what a small surface they present. The petioles are flexible in many trees, like the Maples, and especially the Poplars, and in the wind they allow the leaf-blade to assume a position parallel to the direction of the wind, thus presenting to it only the edge. The Silver Maple probably suffered more from the storm last May than any other trees. Scarcely a tree touched by the storm is left unbroken, and most of them have lost the principal branches or even the whole crown. The trees are well rooted, and the brittle wood, with its mass of foliage, is easily snapped off. *Ulmus Americana* suffered principally because the heavy spreading top with its slender branches is in such a position that they were easily split off. The irregular growth of the fibres makes the wood very tough, though it is only moderately strong. Where no weakness in the structure of the trees exposed them to injury, this species has withstood the storm remarkably well. In Lafayette Park, where everything else was almost totally destroyed, some Elms, full of branches, remain standing, though in many cases the branches are bent out of their original position. Trees of *Liriodendron Tulipifera*, in consequence of their weak brittle wood, were broken off through the main trunk. The Basswood suffered in about the same way. The Osage Orange of our hedges has very strong, tough wood, but the results of the storm show that it is easily split and uprooted. The large leaves, as well as a poor root system, allowed many Catalpas to be uprooted. The wood is not strong, but the number of branches partly twisted off shows that it is not so easily broken as some stronger woods.

The Oaks are among the strongest woods, and were scarcely injured. Most of the Oaks are as well able to withstand wind storms as any trees we have. The trunk is excurrent and the gnarly lateral branches are very thick and strong. The trees are also very well rooted. Many trees of *Populus monilifera* are still standing about the city, though this tree has weak wood and grows so rapidly that it is little protected by other trees. *Ulmus campestris* and *Liquidambar Styraciflua* were little injured. Their salvation was in their form, a strong

excurrent growth with small horizontal branches and most of the wind-exposed surface toward the base. The latter tree has rather brittle wood, which breaks under comparatively little transverse strain. *Gleditschia triacanthos*, with its wide-spreading top and slender branches, we should expect to find much injured, but even isolated trees have stood well. The wood is strong, tough and elastic, and the finely divided leaves are not sufficiently abundant to offer much resistance to winds. Among those trees that escaped almost uninjured is *Taxodium distichum*, the Bald Cypress. The tall pyramidal shape which this tree takes in cultivation in our parks, so different from the wide-spreading tree of the southern swamps, offers very little resistance to the wind. The strong, elastic, almost whip-like trunks simply swayed back and forth in the gale without breaking or uprooting. Other conifers like the heavier Pines were uprooted.

#### A Chrysanthemum Disease.

LAST season the attention of this Department was called to a peculiar disease of Chrysanthemums in this section, which was confined wholly to the variety Philadelphia. Mr. Robert Miller, of Messrs. Strauss & Co., first noticed the trouble which had appeared on his plants while he was absent for a week. Although other varieties were in the same house with the Philadelphia and on the same bench, they showed no evidence whatever of the disease. The affected plants had numerous yellow spots or blotches on the leaves. The spots were irregular in size and shape

Fig. 37.—Sun-print of a diseased leaf of Chrysanthemum Philadelphia.

and stood out in striking contrast to the green portions of the leaf, especially if the latter was held between the eye and the light. In the case of Mr. Miller's plants, the leaves formed during his absence were most seriously affected, while those which had developed after he had taken personal charge were in most cases free from the trouble. In many instances a minute puncture was found near the centre of the spots. From this and other facts it seems probable that the disease is due to some inherent characteristic of the variety, by virtue of which it reacts quickly

to any injury either in the shape of insect bites or punctures, improper watering or feeding, etc. The variety, in other words, is constitutionally weak and needs only a very slight disturbance to cause a local breaking down of the cell contents, followed by the effects already noted. Several insects were present on the plants, notably leaf-hoppers, aphides (green and black), and a species of thrips. These insects were present, however, to a limited extent everywhere in the houses, and the marks of their bites and punctures were seen, unaccompanied by any further injuries except in the case of the variety named. Figure 37 is an illustration from a sun-print of a diseased leaf. The dark spots in the picture show the position of the yellow discolorations. It would be interesting to know if this disease attacks the same variety elsewhere.

It may be well to call attention here to the fact that there are many cases of yellow spotting of the leaves of greenhouse plants which can in most cases be traced to an improper use of water in its application to the soil and to a neglect of the right conditions of temperature, humidity, etc., in the houses. It is unnecessary to go into all the details of the changes in the vital functions of the plant which may take place under such conditions. Suffice it to say that as the tissues become waterlogged, groups of cells being thus disabled from manufacturing food, use up what they already contain, and when this trouble reaches a certain point yellowing and other changes follow. When a plant gets into this abnormal condition the bite or puncture of an insect will often hasten the changes, which eventually result in the formation of yellow, brown and various colored spots. Certain fungi, too, find these more or less disorganized areas excellent feeding ground, so that they come in and complete the work. Too often only the insect or fungus is seen and considered, the fact being overlooked that they are only links in a chain, as it were, and oftentimes not very important ones at that. All this means that to be successful with plants under glass or anywhere else we must first learn to know them, feel their needs, and thus be able to keep them healthy, vigorous and productive. In many cases the presence of insect pests and fungous diseases is only evidence that the grower is not in close touch with his plants; that he is neglecting some of the fundamental principles underlying their growth, and that until these principles are recognized he cannot hope to attain the highest success in his art.

#### Foreign Correspondence.

##### London Letter.

**KALANCHOE FLAMMEA.**—This is a new introduction from Somaliland which is now flowering for the first time at Kew. It possesses all the characters of a distinct and beautiful greenhouse plant, so that it is certain to become popular. The stems are erect, about a foot high, clothed with opposite spatulate fleshy leaves from two to three inches long, and an erect, long-stalked sub-paniculate cyme of many bright scarlet flowers, brilliant as a soldier's coat. Each flower is three-quarters of an inch wide, or about the same size as the flowers of *Crassula coccinea*, and as they are sub-umbellate they present heads five inches across. The plant has been in flower a month or more and will last for some weeks longer. It produces basal growths freely and promises to ripen seeds. The genus *Kalanchoe* consists of about thirty species, chiefly native of tropical Africa. It is related to *Crassula*.

**VITIS VOINIERIANA.**—This is a suggested new species in the way of *Voinieriana antarctica*, but of much larger proportions. It is being distributed by Monsieur Sallier, nurseryman, Neuilly, France, who recommends it for outside cultivation in the west and south of France and for winter gardens in England. It has been received by Monsieur Charles Baltet from Monsieur Voinier, of Tonkin, who found it on the Nin-Binh mountains in Laos, where it clammers over rocks, etc., like Ivy, but so vigorously that,

according to Monsieur Voinier, it would soon cover a cathedral. It has stout Rhopala-like stems and alternate trifoliate leaves with long stout petioles, each leaflet being oblong-obovate, four inches by five, the margins serrate, the nerves very prominent, rich glossy green above, the under surface covered with soft hairs. It is said to have enormous grape-like fruit, with large seeds, and to be of peculiar flavor. A plant of it recently added to the Kew collection bears out this description in regard to vigor of growth and the characters of the leaves.

**ESCALLONIA LANGLEYENSIS.**—Messrs. J. Veitch & Sons have raised this hybrid Escallonia by crossing the well-known *E. macrantha* with *E. Philipiana*. They showed it in flower at a recent meeting of the Royal Horticultural Society, and although it failed to win a certificate it was of interest to growers of hardy plants by reason of its intermediate characters, the flowers and leaves being at least twice as large as those of *E. Philipiana*. The color of the former is pale rose, and they are arranged in dense clusters on the branchlets toward the ends of the stronger shoots. It is likely to find favor as a plant for gardens near the sea in the warmer parts of this country where Escallonias are effectively planted, both as fences and in shrubberies. *E. Philipiana* is quite hardy at Kew, forming a handsome shrub and flowering freely in June.

**EXACUM MACRANTHUM.**—For many years this beautiful tropical Gentianad has been successfully cultivated at Kew, but it has not yet become a popular garden plant, although several market growers near London have essayed its cultivation. It has numerous erect stems, from one to two feet high, clothed with rich green elliptic-lanceolate leaves three inches long and bearing terminal many-flowered corymbs of rotate deep blue flowers nearly two inches across. It is a biennial and requires the conditions of an intermediate house. This year the plants at Kew are exceptionally vigorous, and this is due to their having been planted out in beds of loam in the newly erected Mexican house. I have also seen beautiful pot specimens grown along with Begonias. The plant is a native of Ceylon, where it is said to be common up to 5,000 feet elevation. It is the only one of the twenty species known that possesses any merit as a garden plant.

**ADIANTUM BESSONIANUM.**—I noticed this new Fern several months ago, when it received a certificate from the Royal Horticultural Society. We have since grown it at Kew and have now plants of it two feet across. It is, according to Mr. Baker, one of the many forms of *Adiantum tenerum*, but differs from all in its short stout fronds, the pinnæ of which are exceptionally thick in substance and which densely overlap each other, as in the smaller *A. Pacottii*. For the discovery and introduction of this plant we are indebted to Mr. Hart, of Trinidad. Last week seventy large imported plants of it were sold at one of the London auction-rooms. For garden purposes the name *Bessonianum* may be treated as specific, *A. tenerum* as now constituted being almost generic. It includes such widely different Ferns as *A. Farleyense*, *A. Lathomii*, *A. Victoriae*, *A. rhodophyllum*, *A. princeps*, etc.

**VICTORIA MEDALS.**—The Council of the Royal Horticultural Society has commemorated the diamond jubilee of Queen Victoria's reign by awarding medals to sixty of the most distinguished horticulturists in the British Empire. It is intended to maintain the number of sixty by filling up the gaps made by death, so that in time the Victoria Medal of Horticulture will be a coveted prize. It is as impossible to find sixty horticulturists who stand above all their contemporaries in professional ability as to find the sixty handsomest ladies or largest babies in a large community. A considerable number of those at first selected by the Council have for various reasons declined the honor. It may interest many of your readers to see who have been finally chosen for this distinction.

Botanists: J. G. Baker, F.R.S. (Kew), I. B. Balfour, F.R.S. (Edinburgh), Rev. Henslow, Sir J. D. Hooker, Dr. Morris, (Kew).

## Plant Notes.

**RUDEBECKIA GOLDEN GLOW.**—We have no lack of bold yellow flowers from midsummer onward, and yet additional experience with this *Rudbeckia* commends it for a place in the wilder parts of the hardy plant border. As we have before stated, it is probably a double form of *R. laciniata*, a species which is not often seen in cultivation. It is really a plant of distinct character, with attractive foliage and abundant bloom. The stems are at this season quite six feet high, and although they bear up fairly well against storms and winds they would be the better for some support. In the July number of *The Mayflower* it is stated that this double *Rudbeckia* was probably sent to Mr. John Lewis Childs by a correspondent from Stephenson County, Illinois, where it is said to grow wild in open woods, and is popularly known as the Wild Yellow Dahlia. As we have before stated, the color is not a pure yellow, and the flower is somewhat disheveled without having the grace of the Cactus Dahlia. Nevertheless, its hardiness, the ease with which it is propagated, the rapidity with which it increases and its rather stately habit make it worthy of notice.

## Cultural Department.

### Notes on Crinums.

**ALTHOUGH** *Crinum Powellii* came to me with a reputation for hardiness, its reappearance in the border each season is always in the nature of a pleasant surprise, for it is rather a tropical plant in aspect, and, with the exception of one of its parents, *C. longifolium* (Capense), none other of the *Crinums*, I believe, has any claims to hardiness. Yet planted out here in a border sheltered, except to the south, it has endured our winters with the very slight protection of a few leaves or thin layer of ashes, and these possibly may not be required. It is, of course, cut to the ground promptly by the first frost. It is a noble plant with a globose bulb and short neck. It produces fifteen or twenty leaves, some of which are fully four feet long, rather soft in texture and partly channeled. The flowers, eight or ten in number, are borne on a peduncle two feet or two and a half feet high. Those of my specimen are a soft light pink with wide petals about two inches long when well grown. While the flowers are a decided improvement on those of *C. longifolium*, they are inferior to those of its other parent, *C. Moorei*. Where the climate is no more rigorous than this, *C. Powellii* will prove a desirable plant in the garden for its noble habit, distinctness and practical hardiness.

But the most desirable and handsome of the *Crinums* is *C. Moorei*, which is worthy of space under shelter. This species has a round bulb with a straight long neck, from the top of which its handsome leaves stand out obliquely, usually about two feet long and evergreen. New growth commences usually in the winter, and its handsome flowers are produced with

Fig. 38.—Douglas Spruce (*Pseudotsuga taxifolia*).—See page 292.

great regularity in late spring. It is a fine plant for pot-culture and does well when pot-bound if occasionally fertilized. Though I have grown a number of *Crinums*, none of the others, either evergreen or deciduous, interest me particularly. It is too much trouble to shift them out-of-doors for summer growth and store them in the winter, when the same labor can be expended more profitably on a selection of many handsomer *Amaryllids*. *C. pedunculatum* is a species which is retained for the purpose of testing some time its possibilities in the way of growth. With my best efforts at repression, it is now four feet high and is flowering, with a peduncle three feet long furnished with twenty flowers; these are white, with long narrow petals, purple filaments and brown anthers. The bulbs have leafy columns five or six inches in diameter. It appears to be a plant worth trying in a wet warm place in the garden, but not desirable in valuable space under shelter.

Elizabeth, N. J.

J. N. Gerard.

### Flower Notes.

IN his note on the showy *Alströmeria* last week, Mr. Cameron speaks of it as perfectly hardy, which does not seem to be always the case. I have one clump of this plant which has flowered for six or seven years, without fail, and it increases in size and vigor every year, but some of my neighbors find it a difficult plant to keep. Even when in soil that is thoroughly drained, the thick fleshy roots sometimes rot without any apparent cause. Standing water is almost certain to be fatal, and I have thought that perhaps the freezing and thawing in spring sometimes causes injury. At all events, the thriftiest plant I know stands on the north side of a low fence where the ground remains frozen for weeks sometimes, after it has been soft on the south side during the same time.

This has been a trying year for *Cannas*. June was an exceedingly cold month, and those that were first set out-of-doors made comparatively little growth. The advantages of the dwarf kinds are manifest, for the reliable *Madame Crozy*, although hardly more than a foot high, is bearing as many flowers as usual. If the seed-pods are removed as fast as they appear the vigor of the plant will be thrown into the flowers as they continue to appear, and they will improve until frost.

Our common *Clematis Virginiana* is very effective now, as it festoons shrubbery by the roadside, and its rich green foliage and dainty flowers make it worthy of a place in the wild garden or naturally planted grounds. There are some strong-growing shrubs which are not injured by it, so that it ought not to be excluded from park shrubberies. *C. coccinea*, however, is never oppressive, having very scant foliage, so that it wanders through a large shrub with little observation and doing it no harm. Its presence is hardly made known until the bright coral-colored flowers are seen here and there on long stems well above the foliage of the bushes. This is a first-rate use to make of *C. coccinea*, for it has the advantage of blooming in a sparing way all the season through, so that every day a few flowers are produced.

Among our showy wild flowers is *Monarda didyma*, or *Crimson Balm*, whose bright red flowers are common in midsummer in the middle states along shady streams, where it often grows in large masses, occasionally to the height of from three to four feet. It is well worth growing in the garden, where it responds to kind treatment and in deep soil reaches a height of four or five feet, with larger flowers, whose glowing color makes them conspicuous for a long distance. The plant has a fragrance of *Bergamot*, and it is altogether the best of the native species of *Monarda*.

The dark blue flowers of *Platycodon grandiflorum*, an old Bell-flower which has been familiar to gardens for more than a century, are now very beautiful, as they hang gracefully from the extremities of their slender stems. Some of them are nearly white, and they vary through different shades of blue, but those with the darkest flowers are the most effective. The plant has long fleshy roots, which are proof against our coldest winters, and in good soil which does not get too dry in summer they reach a height of three feet and make an interesting picture for a long time.

*Lythrum Salicaria* is not uncommon on the banks of rivers where it has been naturalized, for it is not a native plant, and its growth makes it singularly effective for such a situation. Its spikes of purple flowers are five to six feet high, and they are nowhere more effective than where they can be reflected in the water and have a background of dark foliage. Like the other *Loosestrifes*, the plant needs little looking after when it has once taken hold of the ground, and it keeps in flower a long time. The dealers in hardy plants have two or three well-marked varieties which are worth growing, and all of

them when cut can be loosely arranged in large vases, so as to be very effective where such decorations are wanted.

New Brunswick, N. J.

S. A.

### Zonal Pelargoniums.

GERANIUMS have received considerable attention in recent years from hybridizers, and a long list of good varieties is now in commerce, which for brilliancy of coloring and varied usefulness is hard to equal in any class of plants. A comparison of our two most popular bedding *Geraniums* of to-day with the two most popular sorts of twenty years ago, namely, *General Grant* with the old *Tom Thumb*, and *Pink Perfection* with the old *Master Christine*, will give some idea of the rapid improvement during that time. The gain has been principally confined to the semidouble and single sections. The old stiff double forms are seldom seen now, probably owing to their shy flowering, lanky habit and their stiff-looking trusses. The semidouble ones are most popular and by far the most suitable for bedding purposes, and admirably adapted for winter flowering in the greenhouse, either for general show or for cutting.

The single varieties fade readily under the sun's rays, and do not last nearly so well as the semidouble kinds. They are, therefore, not suitable for bedding purposes, and generally can only be brought to perfection under greenhouse treatment. Their bright flowers are most appreciated during the winter months. To procure the most serviceable plants for flowering, their cuttings, made from firm short-jointed wood, should be struck during July. They should be inserted singly in three-inch pots filled with a free, porous compost composed of equal parts of sand, leaf-mold and turfy loam. With careful shading and watering the cuttings will soon strike root, and should be shifted on as the pots become filled with roots, the final shift being into six-inch pots. The soil for these later shifts need not contain so much sand or leaf-mold, but should be moderately enriched. Occasional pinchings of the points of the shoots will be necessary to keep the plants bushy, and all flower-buds should be removed as they appear.

The aim during the building-up season should be to keep the plants growing freely and at the same time to procure firm short-jointed wood. This can probably be done best by growing them in a cold frame with the sashes off, except during heavy rains, during August and September, removing them inside before danger of frost. For winter quarters they need a bright house with a night temperature of forty-five degrees, and plenty of air admitted during suitable weather. When the flowering-pots are well filled with roots and the plants begin to bloom freely an application of weak liquid manure will be very helpful. They may be allowed to begin to flower in October, and with proper care they will continue to produce an abundance of bloom throughout the winter. The perfection to which they can be brought with a little extra care is remarkable, and cultivators who have never made any special effort with them would be agreeably surprised at the difference it makes.

I always think single *Pelargoniums* the most attractive for greenhouse decoration, though they are not nearly as useful for cutting as the semidouble forms. The varieties are numerous, and all have more or less distinctive features, so that the selection of the kinds one may think the best is largely a matter of individual taste. If asked to name the best varieties of their respective colors I should have no hesitation in choosing *Athlete*, scarlet; *Queen of the Belgians*, white; *Day-break*, pink; *Madame Reydellet*, salmon. But there are so many really good varieties that it is needless to enumerate more.

Tarrytown, N. Y.

William Scott.

### Three Good Conifers.

I RECENTLY saw a specimen of *Pinus parviflora* which was nearly twenty feet high and broader at the top than near the ground, although it was well branched to the turf. The short, silvery white leaves give it a very distinct appearance which is unlike that of any other Pine I know. It is perfectly hardy in New England, and there seems no reason why it should not become as tall a tree as it does in the mountains of Japan, where, according to Professor Sargent, at elevations of more than 5,000 feet above the level of the sea, it is found growing singly or in small groves, and reaching a height of sixty and sometimes seventy feet. The conifers which can be trusted to grow in the gardens of eastern North America are not very numerous, and the fact, therefore, that this beautiful Pine flourishes in this section ought to be more generally known.

Another desirable and hardy Pine is *Pinus Koraiensis*. It

came here originally from Japan, but is a native of the Korean peninsula and the Manchurian coast region. Like *P. parviflora* and our native White Pine, it has five leaves in a cluster, but it is a comparatively small tree, rarely being more than thirty feet high. Its pale green leaves do not fall until the end of three or four years, so that it has the appearance of being more densely foliated than other White Pines whose leaves are shorter-lived. It is perfectly hardy as far north as New England, and its abundant leaves and the bright red color of its young shoots give it a distinct and attractive appearance.

*Abies Cilicica* is a comparatively rare tree in collections, although there are fine specimens to be seen in Mr. Hunnewell's pinetum, and in the Hoopes pinetum at Westchester, Pennsylvania—trees forty feet high, standing in compact, sharp-pointed cones and branching from the ground with pale silvery foliage. This Fir is a native of the Taurus Mountains, and in ancient Cilicia it forms extensive forests at elevations of from 3,000 to 7,000 feet above the sea. It does not flourish, however, in western Europe, because its young shoots, which appear very early, are often caught by late frosts, and for this reason European nurserymen do not propagate it largely, and it has never been a common tree in commerce. Nevertheless, it excelled in beauty by none of the Silver Firs that are hardy here, except the Colorado varieties of *Abies concolor*.

Newport, R. I.

J. L.

### The Bermuda Lily Disease.

THE disease which attacks the Bermuda Lily, so largely forced for Easter decoration in this country, usually destroys from twenty to sixty per cent. of the crop, and no one knows how many of the bulbs are lost in the fields where they are grown. The disease has been attributed to various causes, and an investigation has been carried on by A. S. Woods, of the Division of Vegetable Pathology of the United States Department of Agriculture, for three years past, for the purpose of ascertaining its real character, so as to find, if possible, some hopeful remedial treatment. The result of these studies will soon be issued in a bulletin, but in view of the fact that the bulbs are now coming in, Professor Galloway makes a brief statement in the *American Florist* of the general facts discovered, from which we quote:

The Lily disease is characterized by the spotting and distortion of the leaves and sometimes the flowers and a general stunting of the plants. When the flowers are spotted the plants are unsalable, regardless of the condition of the leaves. Where the flowers, however, and the upper whorls of leaves are not injured the plants may still be sold for certain decorative purposes.

The disease has been attributed to worn-out soil, premature removal of flowers and stems, premature harvesting, improper propagation, bad treatment during forcing, and the attacks of various insects and fungi. All these matters have received more or less attention, and experiments, extending through several seasons, have been made to prove the truth or falsity of the various theories. As a result of the work the evidence is sufficient to warrant the statement that the trouble is not due to any one thing, but is brought on by a combination of factors, involving long-continued improper selection, propagation and cultivation in the field; the work of a mite (*Rhizoglyphus echinops*); injuries resulting from the punctures of plant lice, or aphides, and the attacks of certain bacteria and fungi, notably an *Oospora* related to the one associated with potato scab. The injuries from the mites, aphides and fungi are always more severe on plants which have been weakened by improper methods of propagation, selection, etc., while being forced.

In regard to preventive measures, it is plain that work must begin where the bulbs are grown in the field. Every plant that shows evidence of disease should be destroyed, and only the strongest and healthiest bulbs should be used for propagation. A second selection should be made when the plants from the scales are being transferred to the field. A third selection should be made when the bulbs are prepared for shipment, so as to reduce as much as possible the difficulties encountered by those who force the bulbs. In the field, rotation of crops should be practiced, for bulbs long grown on the same soil will have more of the mites and other parasitic organisms to contend against, and hence will run greater risks of being weakened. The bulbs should be ripened with their stems on and should be dug only when fully matured and rested.

When forced, bulbs should be planted in well-drained, well-

aerated soil, containing not more than one-fourth well-rotted manure. All injured bulbs should be thrown out, and in watering the young foliage should be kept as dry as possible, for it may be injured by having water injected into the tissues. In feeding avoid the use of solutions of horse, cow and sheep manures, as they have a tendency to clog the soil, resulting in asphyxiation of the roots and consequent injury to the top. Soluble chemical foods may be used to advantage, but caution must be exercised in applying them.

## Correspondence.

### Electrical Attraction of Trees.

To the Editor of GARDEN AND FOREST:

Sir,—A Frenchman, Monsieur Dimitrie, in making experiments with the resistance of various materials to the electric spark, has sought to know the reason why the different kinds of trees are so unequally susceptible to lightning. Samples of beech and oak being exposed to the spark of a Holtz machine, showed that the oakwood had been thoroughly traversed by the spark after one or two revolutions of the machine, while for the beech twelve to twenty revolutions were necessary. Black poplar and willow required five revolutions. The woods having a watery sap appear to have offered no resistance to the electric spark, but the resinous woods, on the contrary, exhibited considerable resistance. Trees of starchy constitution, poor in fats, such as the Oak, Poplar, Willow, Maple, Elm and Ash, offer far less resistance than those rich in fats like the Beech, Walnut, Linden and Birch. Experiments with the Pine (which in winter contains an excess of oil, but in summer is as poor as the trees of starchy fibre), show that in the summer season it is as easily attacked by the spark as the Oak, while in winter it offers the same resistance as the Beech and the Walnut.

It was also shown that by extracting the oil (by means of ether) from the walnut and beech wood, they became as susceptible to the spark as the woods of starchy fibre.

Another point of interest in the experiments showed that living, growing woods offered greater resistance than dead wood. Bark and foliage are always bad conductors of electricity, but that is secondary to the conducting power of the tree in its ensemble. Trees, and the parts of trees which are the best conductors of electricity, are more frequently struck by lightning than those trees and parts which are bad conductors. Thus, in the forests of the principality of Lippe, from 1879 to 1885, the trees struck by lightning were 159 Oaks, twenty-one Beeches, twenty Fir-trees, fifty-nine Pines and twenty-one other trees of various kinds. The domain covered by observations showed about two per cent. Oak, seventy per cent. Beech, thirteen per cent. Fir and six per cent. of Pines. The danger would then be five times for the Fir, thirty-three times for the Pine and forty-eight times greater for the Oak than for the Beech.

The danger to trees from lightning is great in proportion to the electrical conductivity of their wood. The influence of this conductivity of trees upon the frequency of lightning strokes is shown by the fact that dead wood (good conductor) is more frequently struck than green wood (bad conductor), and that the trunks of trees are struck oftener (in the Lippe forests 197 times) than the tops (seventy-eight times).

The author discusses the influence of the site and soil upon lightning strokes of trees. He recognizes that the proximity of streams augments the danger. Isolated trees appear to be more exposed than those massed in clumps; but when the electric tension is very high, all trees are liable to be struck.

Chicago, Ill.

Rosa G. Abbott.

### The Vitality of Seeds.

To the Editor of GARDEN AND FOREST:

Sir,—Nine years ago I took up about fifty clumps of Lily-of-the-valley for forcing, which contained seeds from Foxgloves scattered through the bed. The clumps were placed along the edge of the greenhouse path. After the Lily-of-the-valley had been forced and began to die away, seedling Foxgloves came up, and there has never been a spring season since when a large number did not germinate, and this season there are several hundred. Ten years ago last June I planted seeds of *Hibiscus militaris* in the open border, and every year since I have found a number of seedlings; this year half a dozen. In the place where six years ago were planted seeds of Rocky Mountain Columbine, seedlings continue to germinate, although none have been sown there since. Tobacco, Verbenas, Ageratum,

annual Larkspurs, came up for years after in the same place, and African Marigolds are apt to become weeds if left to ripen seeds. *Begonia semperflorens* sowed itself freely last summer, and this spring we have a considerable number of seedlings up. Garden Geraniums often come up after the seed has been in the ground through the winter.

Wellesley, Mass.

T. D. Hatfield.

### Taxation for Municipal Improvements.

To the Editor of GARDEN AND FOREST:

Sir,—Your correspondent, A. O. Glees, in his letter, published July 21st, on *The Cost of City Parks*, has suggested a solution of a vexed question which arises in every special assessment for park and other improvements. I have had some correspondence with the Board of Street Openings regarding a similar matter, and although Mr. Glees' solution appears just, I should like to have some one explain how the scheme proposed can be put into execution. The scheme seems to me impractical, the law and practice being against the plan proposed.

The Law Department wrote me recently as follows: "According to the law as it now stands, assessments are limited to half the value of the property, as found by the Tax Commissioners for the purpose of taxation. When we come to open a street the large unimproved tracts, which are assessed too low, cannot be made to pay their fair share of the assessment, while the small owners who have improved their property, and whose property is valued for the purpose of taxation relatively higher than the large unimproved holdings, have, in consequence, to pay more than their share. So the original injustice is not represented by the relative difference in the amount of taxes actually paid, but they should be increased by the relative difference in assessments made necessary by the disproportionate valuations of the Tax Commissioners."

Here is a condition of affairs detrimental to municipal improvement, and it seems to demand attention.

New York.

Benjamin Doblin.

### Roadside Notes.

To the Editor of GARDEN AND FOREST:

Sir,—When one chances to come upon a piece of road diversified with groves of trees screening it from the sunshine, and a variety of wild growths clothing the space by the side of the track, the thought always comes, why need we have such barren, sun-smitten roadsides? I recently drove over a charming road where wild Grapevines luxuriated in freedom. Sometimes they crept from the track along the grass to the fence which they covered for rods, or they would climb trees and wander over shrubs. *Smilax rotundifolia*, with its globular clusters of berries well formed, made a graceful companion, and clumps of *Monarda fistulosa* were abundant, looking cool in pale purple beside the glowing flame-color of *Asclepias tuberosa*, now in its glory, and spreading over field and lawn as well as roadside. On the north side of a grove, *Rudbeckias* were making a rich display among the white Yarrow. Several kinds of the Hawkweed family were standing erect and stately, their branching tops just coming into flower, a striking feature among the more humble growths, though less brilliant in blossom than many of their neighbors. Here, too, was Pokeweed, *Phytolacca decandra*, a truly regal plant, of which the red-purple fruit is its chief ornament. *Tephrosia*, though out of bloom, added in large patches of pale green an unusual tint. Along moist places, among fringing Willows and Rushes, *Asclepias incarnata* spread its crimson umbels. In shady nooks a pretty pink *Desmodium* was blooming. Such delicacy of color is rare at this season among wild flowers, and even the Swamp Rose, *Rosa Carolina*, is of a deeper hue. Of the latter, beside many fine specimens of usual size, a cluster of bushes were noted that had been cut to the ground by some ruthless hand, and now, though but a foot or two in height, were covered with a profusion of flowers. Upon a shallow pool was growing Water Crowfoot, *Ranunculus multifidus*, and on a running stream *R. aquatilis*. These curious plants are of interest owing to their peculiar foliage, which is submerged.

These wild roadside plants offer a pleasant study to any one who has an eye for natural beauty, and those who make it their business to "clear up" the highway occasionally seldom carry their designs to the extent of drawing away the debris. A little discrimination, however, in eliminating what might prove troublesome, and allowing the rest to grow in a natural way, would add largely to the beauty that is so freely

afforded us, besides giving us lessons in the natural grouping of plants and flowers, which we sadly need.

#### A New Insect Pest in Massachusetts.

SINCE our allusion to the Massachusetts law against the brown-tail moth we have received a *Special Bulletin of the Massachusetts Agricultural College Experiment Station*, prepared by Dr. Fernald and A. H. Kirkland, which gives an interesting account of the insect which is called *Euproctis chrysorrhœa*, although other generic names have been used for it, as *Bombyx*, *Liparis* and *Porthesia*. It seems that on the 8th of May this year word was sent to the office of the Gypsy-moth Committee that some insect was destroying the leaves of the Pear-trees of a citizen of Somerville. An agent of the Department was at once sent there, who found no gypsy-moths, but reported that some other insect had made "tents" at the tips of the branches of the Pear-trees. After a time examination of the caterpillars by Professor Fernald proved them to be the well-known destructive pest of Europe, the brown-tail moth. The males are pure white, with a satiny lustre on the fore wings, which sometimes carry a few black dots and a reddish brown tuft at the end of the abdomen. The antennæ are white fringed with pale yellowish hairs, and the moth measures about one and a quarter inches from tip to tip of the expanded wings. The females have no black spots on the wings, the anal tuft is larger and lighter, and the antennæ are shorter. The expanse of the wings is about one and three-quarter inches. The eggs are laid in July in masses of from two hundred to three hundred, usually on the under side of the leaves, where they hatch in a short time, and the young caterpillars soon leave nothing but the skeletons of the leaves. While still young these caterpillars begin to construct a regular habitation at the end of the twigs by drawing together a few leaves, lining and surrounding them with silk, where they remain all winter. Before the leaves begin to grow, the caterpillars emerge from their winter retreat and feed on the swelling buds. The full-grown caterpillar is sometimes one and three-quarter inches long. When the caterpillars are done feeding they change to pupæ in the early part of June among the leaves, spinning an open cocoon of coarse silk. In a short time the moths emerge, and after mating lay their eggs.

Careful inquiry seems to establish the fact that this insect has been known about Somerville for some five years, and probably it existed in small numbers for several years before it attracted attention, and then it was supposed to be the gypsy-moth. Men employed in destroying the gypsy-moth probably have supposed them to be some common American species, and paid no attention to them, as their work, by act of legislature, was directed against the gypsy-moth solely. The area in which the insect has done serious damage this year is nearly circular in outline, and has a diameter of about a mile. But the pest is already found in single colonies at some distance, and no doubt it has been distributed by traffic to many places from which no report has yet been heard. The Pear seems to be its favorite food-plant, and as these trees greatly outnumber other fruit-trees in the settled portions of Massachusetts, the loss is severely felt by property owners. It feeds, however, on many other trees, and among these the bulletin mentions the following: Basswood, Sugar Maple, White Maple, Sycamore Maple, Plum, Cherry, Wild Black Cherry, Peach, Crab-apple, Apple, Quince, White Ash, American Elm, Black Walnut and Weeping Willow. Of shrubs and climbers the Grape, Virginia Creeper, Wistaria, Raspberry, Weigelia, *Spiræa Thunbergii*, Blackberry, Rose, Japan Quince, Currant and Gooseberry are named. It also feeds upon the Geranium, Burdock Plantain, Rhubarb, Strawberry and many other herbs, so that the number and

variety of its food-plants indicate that it may become a serious pest.

During the latter half of May the caterpillars swarmed from the defoliated Pear-trees over the ground and walks and fences in search of food. Trees in full leaf in the path of this hungry army were stripped in a few days. For example, they attacked a large Cherry-tree covered with dense foliage one morning, and five days later hardly a green leaf remained on the tree and the half-grown fruit was nearly devoured. In a badly infested orchard the noise made by the feeding of these myriad caterpillars could be plainly heard. They crawled over everything, and the sweeping and the washing down of the masses of caterpillars from piazzas and the walls of houses is of daily occurrence. An annoying feature of the invasion was the painful irritation caused by the insects when coming in contact with the skin. The hairs of the caterpillar are brittle and easily detached, and produce an intense irritation when they touch the skin, and in many cases the suffering was so severe as to require the aid of a physician. No birds except the English sparrow have been discovered feeding on these caterpillars, and these took them but sparingly, but the sparrows themselves have driven away our native birds which are known to eat hairy caterpillars, so that in this way they may aid the insects more than they injure them. No predaceous insect has as yet been found attacking them, and no parasites. In Europe it is said that their thick hairs protect them from small birds, but they have many parasites.

As a remedy it is recommended to remove and burn the egg masses in July before they hatch, which can easily be done on shrubs and low trees within reach. While the caterpillars are feeding on the surface of the leaves during autumn the trees should be sprayed with arsenate of lead or Paris green. The most effectual means of destroying the insect, probably, is to remove and burn the tents at the tips of the branches in winter with long-handled pruning-shears for trees of ordinary height, and ladders may be used for larger ones. The tents when cut should be gathered and burned at once. If these methods have been neglected and the caterpillars have emerged from their winter quarters, the foliage should be sprayed at once with arsenical poison. Later, when the caterpillars are very numerous on a tree they may be jarred to the ground by striking the branches with a mallet bound with cloth, and if the ground is then sprayed with a strong kerosene emulsion all the caterpillars with which it comes in contact will be destroyed.

As long ago as the year 1734 laws were enacted in France requiring landowners to destroy these caterpillars. Later the laws were extended to include the gypsy-moth and some other injurious insects, and Belgium and other European countries have passed similar acts. These laws, however, are not rigidly enforced, and since the insect is found almost over the entire continent of Europe, the question of exterminating it is not considered. What is contemplated is the reduction of the pest to comparatively harmless numbers, without considering the question of its spread. In Massachusetts the conditions are quite different, and as the insect is now found within a very limited territory, an attempt will be made to exterminate it. The gypsy-moth is now found over a much greater extent of territory and is a more difficult insect to deal with, and surely if it is possible to exterminate the gypsy-moth the effort to suppress this new pest is worth making.

The wisdom of the act of Congress of 1895, which required the publication of the annual report of the Secretary of Agriculture in two parts, is made apparent by the appearance once more of the *Year Book of the Department of Agriculture*. Our readers will remember that the volume which contains the business and executive matter necessary for the Secretary to submit to the President and Congress is quite distinct from this Year Book, which is made up of papers specially suited to interest and instruct

the farmers of the country and to explain in a general way the operations of the department for their information. It is not our intention to make any review of the contents of the book at this time, which we may say consists of some thirty papers, many of them illustrated, and all prepared by experts in various fields of agricultural inquiry. We give the titles and authors of a few of these papers: "The Use of Steam Apparatus for Spraying," by L. O. Howard; "Some Common Poisonous Plants," by V. K. Chestnut; "The Blue Jay and its Food," by F. E. L. Beal; "Diseases of Shade and Ornamental Trees," by B. T. Galloway and Albert F. Woods; "The Improvement of our Native Fruits," by L. H. Bailey; "Pruning and Training Grapes," by E. G. Lodeman. It will be seen that subjects of this kind, treated as they are by men of recognized standing in agricultural science, are worth more than mere passing notice, and these are followed by a hundred pages of tables, statistics and condensed information, arranged for convenient reference. In a prefatory note by Assistant Secretary Dabney it is stated that these condensed statistics, together with practical recipes and directions, have been prepared with a view of making this appendix a vade mecum for the farmer, so that the series of Year Books, which are thoroughly indexed for this purpose, will become a reference library of increasing value to the agriculturist. An edition of 500,000 copies of the Year Book has been issued for free distribution, and the only regret we have about this publication is that it has not been more carefully edited. Of course, this defect is well known to Mr. Dabney, who states that the material for this and the two preceding volumes of the series has been prepared by busy scientific workers in the intervals of other duties, and the only revision the work has received has been such as it was possible for an executive officer to give, who only had one assistant to help him. Since it has become the annual practice to issue such a volume and publish it in so large an edition, a wise economy suggests that it should be carefully revised and edited by a corps of trained specialists.

Mr. John G. Lemmon contributes to the second part of volume ii, of the *Bulletin of the Sierra Club* a paper on the California Conifers, which will aid, no doubt, the enterprising and energetic climbers of the club to recognize the trees they encounter in their mountain excursions and thus to be in a position to add to our knowledge of the distribution of the Conifers of the California Sierras. Mr. Lemmon's arrangement and treatment is practically similar to his previous works on the same subject. The present part is devoted to *Pinus* and *Larix*, to be followed in a succeeding number of the bulletin by an account of the other genera of Conifers. We notice that Mr. Lemmon recognizes more species of *Pinus* than other observers consider desirable, but, after all, the limitation of species is largely a matter of judgment, and Mr. Lemmon's opportunities to see these trees in their native haunts has been surpassed by that of only a few other observers.

### Notes.

Redwood has been tested for paving purposes in San Francisco, and experiments have proved that it is a satisfactory material. This means probably an increased demand for Redwood timber and the more rapid felling of the limited supply of that timber now standing.

*The Gardeners' Chronicle* states that many letters have been received by the editor in reference to the Victorian medals spoken of in our London letter of this week. Some of these are written in a strain of indignation, but they generally treat the humorous side of the question. The editor makes the wise comment that, considering the delicate nature of the circumstances and the excellence of the intention, a discreet silence will be most acceptable to all concerned.

To prove that Indiana can still turn out some of the best oak on the continent, *The Northwestern Lumberman* states that thirty carloads of oak ship-timber have been sent from Wabash to Toledo in sticks from thirty to forty feet long and

sixteen inches square. It goes to Buffalo for use in building vessels for the lake marine. Of late years Indiana farmers have not been disposed to rush their timber to market regardless of prices. The result is that much good oak is still found in that state.

Peas, string-beans, celery, corn, cucumbers and eggplants may now be had as fresh as they ever reach the city buyer, since much of the present supply of these vegetables comes from Long Island, New Jersey and other near-by points. Turnips, carrots, potatoes, cabbage, onions and peppers also come from neighboring farms, as do tomatoes, while Lima beans are supplied from Maryland and red sweet potatoes from Virginia and North Carolina. Cauliflower and squashes are among the staple vegetables of the season, but the gathering and shipment and sales of all these products have been seriously interfered with by the frequent heavy rains of the past two weeks.

In view of the attention which the flowering of *Lathyrus splendens* at Kew has attracted, Dr. Franceschi writes to say that the color of these flowers is hard to define, but that it is rather a shade of crimson than of scarlet. This Pea only grows in the extreme south of California and in Lower California, being a native of the high desert region of the interior. It adapts itself, however, to liberal watering, and in this case, with sufficient drainage, it will continue to grow and flower all summer, and not die down as it does in its native habitat, where it is essentially a winter bloomer. Since frost often occurs on these highlands, Dr. Franceschi predicts that it will prove hardy in those parts of England where *Romneya* and *Fremontia* have been grown successfully.

*The Fruit Trade Journal* quotes a complaint from Florida about the scarcity of fruit in that state. Of course, there is no lack of oranges and grape-fruit in the winter, and of berries, pineapples, pears and grapes in spring and early summer, and in the autumn there are some bananas. But just when other states have an abundance of fruit and fresh vegetables—that is, in late summer and early autumn, there is a deficiency which needs to be supplied. It seems odd to northern gardeners that vegetables should be lacking at the season which is most productive here, and we should think that even if irrigation or generous fertilizing was required, there ought to be no lack in Florida gardens at this season. As for fruits, the problem is more serious, but the wide-awake horticulturists of that state ought to be able to keep a subtropical climate in full producing power all the year round.

A discussion of the merits of the newer Sweet Peas takes up a considerable space in *The Florists' Exchange* for the current week. Ordinary growers do not appreciate some of the alleged improvements in these flowers, and it is impossible to discover any real difference either in form or color or habit in some of the varieties sent out. What we wish to call especial attention to is that while Mr. Eckford has for many years been the hybridist to whom the world looked for the best work in this direction, many beautiful varieties are now produced in this country. Some of the seedlings of Burpee, at Ford Hook, Doylestown, Pennsylvania, and those of Walker, an expert who is working in Oregon, are said to be equal, if not superior, to any forms hitherto raised. It is said that Mr. Burpee made 373 separate tests this year, of which 348 were of named varieties and the remaining 25 of mixed kinds.

We have already alluded to the fact that we are not getting a single bunch of bananas from Cuba, although formerly at least 2,000,000 bunches came from that island every year. Of course, there is no lack of the fruit in this country, for Jamaica, Porto Rico and other islands, Mexico and Central America have all increased their exports to supply the market, and so energetically have they carried on the work that bananas are now cheaper than ever, and the supply has kept increasing to meet a constantly growing demand. Materially, this must be a great loss to Cuba, and, indeed, it is a loss to American capital, for the great importing firms had plantations covering thousands of acres, and eastern Cuba was rapidly becoming a continuous banana garden. A large part of the plantations have been destroyed during the war and the most fertile part of the island is now producing nothing of value.

Mr. Charles A. Keffer, in writing on the forest fire laws of Minnesota, says that legislation of this sort acts quite as much as an educational as a prohibitive force. In his travels through Minnesota, in both prairie and forest regions, Mr. Keffer frequently saw copies of the law in schools and post-offices. Otherwise careless citizens have thus had their attention called to this important matter, and the most prolific cause of forest

fires, thoughtlessness or carelessness, has been averted; for there can be no question that neglect or lack of proper care in the kindling and extinguishing of useful fires is a most prolific source of danger to the forest. The pleasure-seeker, whose attention has been attracted at every station between his city home and his outing-place, is awakened to the damage his carelessness may cause. The woodsman, to whom life-long familiarity with camp-fires has only brought indifference in his handling, will be arrested and restrained by the knowledge that such carelessness is criminal. The railroad employee will be more and more careful in cleaning his right-of-way, knowing the danger of dismissal which is likely to result if his company is held responsible for damage that he has caused.

The Maryland peach crop, especially that on the Eastern Shore, was seriously injured by a frost on the 20th of April, which killed a large portion of the fruit-buds in the tidewater section of the state. But it is true also that the curculio has done an uncommon amount of injury, as the great number of specked peaches coming to this market indicates. Peach growers have never felt the necessity of combating the curculio as plum growers are compelled to do. And certainly they have not yet taken ordinary precautions against this danger. Last year the peach crop was unusually large and the overloaded trees produced much small and inferior fruit, which was allowed to remain in the orchard. This gave the curculio an unusual opportunity, and Professor W. G. Johnson, the state entomologist, suggested to the growers last fall that it would be wise policy to destroy as many of the small peaches as possible so as to prevent the larvæ of the curculio from entering the ground for pupation. There is no doubt that if this had been done the crop would have been less seriously injured. The fact that Professor Johnson predicted this danger ought to lead peach growers to listen more carefully to expert counsel in the future.

Certain species of *Cattleya*, notably the ever-varying forms of *C. Gaskelliana*, are found in the highest branches of the giant trees which form the primeval forests of many of the valleys of Venezuela. In order to get the best plants these trees are felled, and from the harvest thus produced only the very finest plants are taken, the smaller ones being left to perish with their natural supports on the ground. In writing of these facts, a correspondent of *The Orchid Review* says that many valleys are thus stripped of their virgin forests and many of the finest species of Orchids are being surely exterminated. Even now the well-known *Oncidium Papilio* is getting scarce in Trinidad. Mention is made of a collector who took 1,500 fine plants of *Cattleya Gaskelliana* from Venezuela, but in order to do this he had cleared out a valley and left 10,000 small plants and seedlings to perish. Only plants like the 1,500 selected ones would meet the demands of his London employer, and the enormous cost of transportation from any distance inland in South America makes this destructive system necessary to one who wishes to make his expedition pay. It is to be hoped that the Government of Venezuela will put some check on this vandalism, as has been found necessary in other countries.

Delaware, Niagara, Moore's Early and the small green Thompson's Seedless grapes are all represented in our markets now, and come from South Carolina and Georgia. Black Hamburg and White Muscat of Alexandria grapes, from Newport glass houses, are seen in the fancy-fruit stores, and sell for \$1.50 a pound. Alligator pears, from Caraccas, were seen here last week, and some of the same fruit has since arrived from Colon. Green ginger-root, from Jamaica, is one of the latest receipts among new products of the season, and the first eastern apricots are now arriving from the interior of this state. The supply of pineapples is beginning to decline, but many other fruits, such as apples, pears and plums, are coming in increased quantities, and indeed the supply of fruits in this city was never larger nor more varied. During last week eighty-four car-loads of California fruits were sold here, the largest weekly sale made this summer. Tragedy prunes are especially plentiful, as are Bartlett pears, and the latter are now of large size and highly colored. Decker, Foster and Early Crawford peaches are among the best sorts now coming from California. A few peaches are coming from New Jersey, Delaware and Maryland, as well as from North and South Carolina and Georgia, but none of these are of the first quality. Even the largest and best in baskets containing eighteen selected fruits for \$1.00, are only notable for their extra size, since they lack color and flavor. Wild Goose plums and cherries, from near by, are becoming scarce, and raspberries and blackberries have proved perishable stock during the persistent rains of the past fortnight.

## The Use of Trees and Shrubs with Leaves of Abnormal Colors.

A BOSTON correspondent writes in a discouraged tone about the planting he observes in the suburbs of that city. It seems to him that popular taste is setting strongly toward *Prunus pissardi*, the Golden Elder, variegated *Negundos* and the like. We have no doubt that too many trees and shrubs which are valued for the abnormal coloring of their leaves are used about Boston, and, in fact, about every other American city. Unless our own observation is at fault, however, the tendency of public taste, as a rule, is in the other direction, by which we mean that the people who plant nowadays are more inclined to follow the teachings of nature in this respect than they were a few years ago, when the tree agent, with his highly colored catalogues, was more pervasive and influential than he now is. The so-called foliage plants with brightly colored leaves and hues, set in patterns of various sorts, are certainly not as prevalent as they once were, and it is very evident that in American parks the use of shrubs and trees with streaked and spotted or vari-colored leaves is not as profuse as it is in European parks. Perhaps, our correspondent in some afternoon drive has observed several glaring offenses against that quietness and self-restraint in planting which alone can make home grounds homelike, and this has depressed his spirits.

First and last, we have often discussed the principles which ought to underlie the art of garden design so far as it relates to the selection of trees and shrubs for some peculiarity of form or of color. It would be an affectation of severe taste to lay down a rigid and invariable rule that no plant should be used whose individuality was so pronounced that it might be called abnormal. In the hands of a skilled artist a plant with yellowish or wine-colored leaves might be used occasionally as a climax in a gradation of color. Nature herself gives a wide range to select from between the sombre tone of the dark green foliage of certain Pines and other conifers to the pallid gray of the Lead-plant, the silvery tints of the *Elæagnus* and the almost snowy leaves of our native *Hydrangea radiata* when they are disturbed by the wind so as to show their under side. There is no fear that our natural landscapes

shall ever be of that "vapid green" which is depreciated by the rhyming gardener in his well-known lines. But with all her variety nature rarely, in our northern latitude, produces variegated leaves. It is true that in the autumn we have a wealth of color in the foliage of every landscape, and as the leaves come out in spring they take on tints even more delicate and quite as remarkable in their range. But both these displays are transient. Much of their beauty consists in the fact that it is evanescent, just as our most luxuriant displays of blossoms in the flowering time of the Dogwood and Rhododendron and Judas-tree and Crab-apple clothe many a forest border with a beauty which is as profuse as it is fleeting.

These are the two real objections to the free use of plants with vivid foliage. They are unnatural, or, at least, they are alien to our climate, and they are monotonous. Nature occasionally produces a freak, but it is not in accordance with nature to multiply these oddities until they become prominent features in the landscape. A *Negundo* with pale and sickly foliage may be a chance production of nature, but nature never produced these pallid trees in such comparatively large numbers as they appear in certain European parks. Nor did any one ever see in nature such masses of purple Barberry or Golden Elder as we see in many private grounds in America. When we exalt what is rare and accidental to the place which ought to be occupied by the typical and normal vegetation of our climate, we are forcibly subverting the laws of nature and substituting devices of our own invention. It is not simply because we are introducing high colors into the landscape, for few countries in the world have scenery where abundant bright-hued flowers are more characteristic. But plants with golden leaves or variegated leaves are alien to our native silva, and when we use them in profusion we introduce a new motive altogether out of harmony with our natural landscapes.

Again, one of the characteristic beauties of an American landscape is its constant change. Between the delicate beauty of the tender leaves of our woodlands and roadside thickets in spring and their rich colors in autumn, there are new pictures every day as the foliage changes in form and color. We have meadows full of buttercups to-day, and daisies to-morrow. Our mountain slopes are now purple with the flowers of Rhododendron, and again pink with those of *Kalmias*; while from midsummer to autumn Sun-flowers and Rudbeckias, Asters and Golden-rods keep our landscapes in continued transformation. For this reason we never tire of them, as we should, perhaps, if the Rhododendrons bloomed all summer through, or if our forests from May until November presented in unvarying profusion the rich colors they show in October. And here is the fundamental defect of the trees and shrubs and plants with variegated and bright-hued foliage. It is not only that their colors are unnatural, but they are unchanging, and consequently to the last degree monotonous and wearying.

## Two Southern Botanical Worthies.

COMPARATIVELY little is known of Thomas Walter, an Englishman who wrote, under the title of *Flora Caroliniana*, an account of the plants of South Carolina, where he lived and died. Many years ago Mr. H. W. Ravenel, of South Carolina, published in the Proceedings of the Elliott Society (i., 54) a transcription from the stone which marked Walter's grave in his garden on the banks of the Santee River in St. John's Parish. The stone was erected "In memory of Thomas Walter, a native of Hampshire, in England, and many years a resident of this State. He died in the beginning of the year 1788, *Ætatis* cir. 48 Ann. To a mind liberally endowed by nature, and refined by a liberal education, he added a taste for the study of Natural History, and in the department of Botany, Science is much indebted to his labors. At his desire he was buried on this spot, once the garden in which were cultivated most of the plants of his *Flora Caroliniana*,

From motives of filial affection his only surviving children, Ann and Mary, have placed this memorial."

Dr. Mellichamp, of Bluffton, South Carolina, now calls our attention to Professor Frederick A. Porcher's History and Social Sketch of Craven County, South Carolina, published in the April number of the *Southern Quarterly Review* for 1854, from which we extract the following paragraph relating to Thomas Walter:

One citizen of this parish has earned for himself a name in the world of letters, and it is strange that Ramsay, who appears eagerly to have sought after Carolinian celebrities, should have entirely ignored his existence. Thomas Walter, an English gentleman whose devotion to the cause of science led him to the wilds of Carolina, was attracted by the charms of Miss Peyre, of St. Stephens, married her and settled there. He devoted himself particularly to the pursuit of botany, and the curious are still occasionally rewarded by a visit to his garden, the ruins of which may still be seen near the banks of the Santee Canal. He is the ancestor of one branch of the Porcher family, and of the Charlton family of Georgia. His book, the *Flora Caroliniana*, which was printed in London in 1789, is dated ad Ripas Fluvii Santee, 30 Dec., 1787.

Dr. Francis Peyre Porcher, the well-known author of the Resources of Southern Fields and Forests, Medical, Economical and Agricultural, who died only a few months ago at a great age, was a grandson of Walter.

In this same article in the *Southern Quarterly Review* is the following note concerning Dr. James McBride, best remembered as a botanist for the assistance he gave Elliott in the preparation of his *Sketch of the Botany of South Carolina and Georgia*.

Science and humanity mourned in 1817 the untimely death of Dr. James McBride. He was a native of Sumter District, South Carolina, and was educated at Yale College, where he was a contemporary of Mr. Calhoun and of our late revered Bishop (Xtopher Gadsden). He engaged in the pursuit of medicine and, settling in Pineville, married Miss Eleanor Gourdin, daughter of The Honorable Theodore Gourdin of that village.

As a physician he was eminently successful, and he was distinguished for sound judgment and a thorough knowledge of his profession. He removed to Charleston to enter upon a wider field of practice, but before he had time to reap any of the promised fruit fell a victim to yellow fever. The opinions of Dr. McBride are treasured to this day and quoted with respect. He had an intuitive perception of truth in matters which were the subjects merely of conjecture, and subsequent researches have proved the accuracy of his judgment. His recreation was botany. He was the friend and correspondent of Elliott and assisted largely in the preparation of the Botany of South Carolina and Georgia. Mr. Elliott acknowledged the obligation, and in the preface of his work has paid a touching and affectionate tribute to one who richly deserved his regard, and could fully appreciate his own genius.

#### Notes on the Codling Moth.

NOTWITHSTANDING the fact that the codling moth is one of the oldest and best known of the apple enemies, and one which it has been supposed that we long ago knew how to control, it quietly goes on its way from year to year destroying more fruit than any other one enemy, and perhaps more than all other enemies together. It became evident a year or two ago that something was wrong in the generally accepted doctrines in regard to this insect. At the experiment station here and among growers in the state it gave much trouble, in spite of spraying as commonly advised and practiced. Accordingly, in the spring of 1896, observations were begun in the horticultural department to determine, if possible, what was the matter. Much time was spent on the subject and a good deal learned concerning the habits of the larvæ, but not all of the life-history was settled. We looked in vain for the eggs, notwithstanding the fact that large numbers of them were doubtless right before our eyes and passed by unnoticed or as having no connection with the subject in hand. This year we have been more fortunate. Through the assistance of William Nutter, of Gibbon, Nebraska, a large apple grower who has suffered great loss through the ravages of this insect, and who determined to go to the

bottom of the subject, we have been able to get large numbers of moths and eggs in profusion. Few entomologists, apparently, have detected the egg of this insect, and the old statement that it was laid in the calyx has been handed down from generation to generation of horticultural literature until Professor Washburn, of Oregon, described and figured it as found on the surface of the apple.

Instead of being laid in the calyx, we find that the eggs are laid almost exclusively on the upper surface of the leaves. Only rarely is one found on the apple or on the under side of the leaves, in the orchard, though in confinement they may be laid anywhere. At least, this has been true up to this time. It may be, however, that the later eggs, when the apples are large, may be oftener found on the apple itself. They are usually found on leaves of a cluster associated with an apple. The egg is about the size of a pin-head and looks not unlike a small drop of milk. Apparently many sterile ones are laid, or the ovule perishes for some cause. These are whiter and more shining than the fertile ones. Just before hatching, a black spot develops in the centre, which is the head of the young larva. When first hatched he is a tiny fellow about an eighth of an inch long, but as spry as a cricket. His head is then the most prominent part of him. He immediately begins to hunt for a hiding-place, and the most convenient one is often that formed by the closed calyx cup into which he enters to begin his work. About eighty per cent. of the larvæ hatched in the orchard during the early part of the season have entered by that means. If two apples hang together or if a leaf hangs over one and close against it that appears to suit them just about as well.

So much for the general habits of the insect, but how to catch it is quite another matter. The orchard on the experimental farm was in full bloom and many petals beginning to fall this year on May 6th, except the Janet, which blooms later than other varieties. Two or three days later the bloom had fallen. About May 10th, then, would have been the time to do the first spraying as ordinarily recommended. The calyx cups were watched in order to determine how long this spraying might be delayed, and still be done before they closed. The first spraying was done May 18th, but had been delayed a little too long, for many of the calyx cups were then nearly closed. Apparently the best time would have been about a week after the blossoms fell, or ten days after the time when the trees were in full bloom. This would have been about May 15th this year, our season having been later than usual. By following the sprayer I found that ordinarily we do not get the calyx thoroughly drenched. For this reason the spray was made coarser than heretofore, and this seemed to work better, particularly when applied with considerable force. It appeared to be easier to get the poison into the cavity when the lobes were wide open than when they had begun to close, making a vase-formed receptacle. The leaves increase in size very rapidly after the blossoms fall, so that on this account the sooner the spraying is done the more thorough is it likely to be. Were there no danger that the poison would be washed out by rains, the best time to apply it would be immediately after the blossoms fall. On some varieties the cup never closes, but on most kinds it was practically closed by May 20th.

But where is the codling moth? At this time, which it will be observed is about the time ordinarily recommended for spraying, there are no worms, and no eggs even. The first eggs were found in the orchard this year on June 3d, though some may have been laid a few days before that. The first larva was found June 12th, large numbers of them appearing from the 12th to the 15th, nearly a month, be it observed, after it was necessary to spray in order to get poison into the calyx cup. Very plainly, then, the success of spraying at that date depends upon getting poison into the calyx cup and having that close over it and holding it there until the larva comes. Therefore, the later the poison is applied while the calyx is still open the better.

Practical experience has proved that treatment at this time is effective. Still this is not a panacea, for if only about eighty per cent. of the worms enter at this point the remainder can abundantly people the orchard in time to get in their work on the winter fruit. What shall be done with this twenty per cent. is the question we are trying to solve; also what shall be done with the surplus moths which may drift across from the orchard of our neighbor who does not spray. Whether later sprayings, which must depend on clinging to the surface of the apple for their effectiveness, will succeed is an unsettled question. Ordinary sprays quickly run off the surface of the apple or gather in little drops, so that they do not form much protection. The addition of lime, soap or a combination with Bordeaux mixture will apparently help this some, but it is impossible to say how much. We hope to be able to answer some of these questions by the end of the season. Still, the fact that the young larva seeks for a sheltered place to begin eating may be of service, for the spray is more likely to cling about the stem or the calyx, or where another apple or a leaf touches the fruit. Another difficulty appears, however. The larger worms simply dig their way into the apple without eating, tearing out and throwing down the pieces of apple. Probably the same holds true of the small ones, which makes the fight more discouraging.

Several lines of warfare are open, however, and I am sure that some of them will prove effectual and practical. The eggs are very easily accessible, being laid as they are on the upper surface of the leaf. In a limited way in laboratory experiments we have found that kerosene emulsion will destroy these, but we are not yet able to say whether a strength that may be safely used will prove effective in field work. We are also trying Bordeaux mixture for the same purpose. Whether the pupæ can be destroyed by any caustic preparation is a question which may well be asked, though it is doubtful, because they are so well protected with their silken covering. This year the first pupa was found June 25th, and great numbers of them were to be found by the 28th. The larva turns a pinkish color when ready to enter that stage and seeks a hiding-place beneath the scales of bark or similar protected spot, not far from the ground, usually within three feet. The rough places in the forks are favorite hiding-places. Some caustic spray or wash at the right time might destroy many of these. Then, too, I believe that the old method of trapping the pupæ with bands has possibilities worth considering. Last year we were able to catch large numbers in this way. A more practical modification of this consists in cutting strips of heavy express paper on a slight curvature, folding it together once and tacking it around the tree. This makes a convenient hiding-place for the insects when ready to pupate. If the loose bark of the tree is scraped away and the trunk kept smooth and clean, these hiding-places would be largely utilized. If applied at the right time they could be left in position a week, quickly gathered up in a basket and burned and replaced by another lot. Two sets ought to answer the purpose and trap nearly all the larvæ which escape the early spraying. Unfortunately, this was overlooked at the right time this year, so that we cannot report upon that point for the first brood. The later broods come along so irregularly that we have found practically one continuous stream of them all summer long.

In confinement we find that the young larvæ eat the leaves readily, sometimes remaining on the leaf where they hatch for twenty-four hours, and eating out quite large pieces. They usually eat away one epidermis and the inner tissue, leaving the other epidermis intact. I am not yet ready to say, however, that they eat the leaves in the orchard sufficiently to make this of any importance in fighting them. We are trying to find this out.

Our experimental orchard is divided into six sections this year. One section is to receive six sprayings, one only the earlier sprayings, one only the later, etc. On June 21st a careful examination was made of trees which had

been sprayed previous to that time, as compared with unsprayed trees. The general average of all sprayed sections at that time was about five wormy apples to each tree, as against twenty-seven a tree without spraying. We find our neighbor's orchard the best hunting-ground.

### London Letter.

CHISWICK.—At a special meeting of the various committees of the Royal Horticultural Society, held partly as a Jubilee commemoration and partly for business, Dr. Masters, F.R.S., discoursed on the present state of the Chiswick gardens and made some suggestions for their better utilization, especially for educational purposes. Their educational value might, he said, be increased by discarding entirely all plants of passing interest or of mere decorative value and cultivating only the principal types of fruits, vegetables and flowers. The best methods of cultivation should be followed and everything possible should be done to make the collection of special interest to horticulturists. Patent and other manures should be tested and reported upon and all the now very numerous insecticides and fungicides put upon the market or recommended, chiefly by Americans, should be tried and impartially dealt with. The educational side of Chiswick might be made more of by the adoption of the Kew system with regard to young gardeners; in fact, there was good reason to hope that a plan could be devised by which Chiswick men could attend the lectures, etc., given at Kew for the benefit of the men there, and that the Kew men might enjoy the advantages of Chiswick in return. He was strongly of opinion that progress in horticulture could only come from a scientific study of the principles of horticulture. English gardeners generally worked by rule of thumb. Dr. Masters referred at some length to the experimental and teaching schools recently established in the United States, the work of which was of considerable advantage to horticulture. Sir Joseph Hooker pointed out that these experimental stations in America were state-aided, a condition of things unknown in this country. He thought the efforts being made with a view to affording more scientific training to horticulturists deserved every encouragement.

EXAMINATIONS IN HORTICULTURE.—I have already noted the annual examinations held all over the United Kingdom under the auspices of the Royal Horticultural Society. It will afford some idea of the character of these examinations if I give the questions set and the report of the examiners. The examiners are mostly young, and many of them are not horticulturists. I know that some of the most successful in the list this year know little or nothing of the practice of horticulture, while, on the other hand, some of those who have not done so well are really capable practitioners.

#### QUESTIONS.—ELEMENTARY PRINCIPLES.—A.

1. What are the three chief mineral ingredients of a soil? Name garden plants or shrubs which delight—each kind respectively.
2. What differences may be expected from growing unripe, perfectly ripe, and long-kept seeds respectively?
3. In transplanting, why is it necessary to preserve the extreme and most delicate tips of the root-fibrils?
4. Why does covering rhubarb redden and lengthen the leaf-stalks and stop the growth of the blade?
5. Describe the structure of a Hyacinth bulb, and explain why the Dutch method of slashing or hollowing out the bottom induces the formation of bulbils.
6. What are the essential conditions for successful grafting?
7. How does the structure of a plum differ from that of an apple? Explain the origin of each.
8. Name the natural orders or families to which the following plants belong: Cyclamen, Rhododendron, Clematis, Stock, Pelargonium, Borage, Potato, Onion, Parsley and Turnip.

#### DIVISION B.—HORTICULTURAL PRACTICE.

9. Explain the process of cross-fertilization in garden flowers,

and give examples of both hardy and exotic plants that have been improved thereby.

10. After seed of the Chinese Primula has been ripened describe the method of sowing and subsequent treatment of the plants up to the period of their flowering.

11. What is the native country of the Celery-plant, and under what conditions does it grow naturally? Give a short account of its culture, such as time of sowing and subsequent treatment.

12. When and under what conditions is Sea Kale found in a wild state? Describe its culture and state the time of the year it is in use.

13. Where is the common Asparagus said to be found in a wild state? State all you know of its culture, and for how long a period it may be had in use.

14. Give an account of the Apple. How are the trees propagated? State what you know of its culture, and the diseases to which the trees are liable, and the remedies. Name one good cooking variety for use in each month from August to April inclusive.

15. State all you know about the Raspberry. What sort of soil is best adapted to its culture? Give method of training and pruning, and the best varieties to cultivate, both yellow and red.

16. Give an account of the usual method of Gooseberry-culture adopted in gardens; and also the Lancashire method to obtain prize fruit. Name six of the best prize varieties and six best for ordinary garden culture.

The examiners were the Rev. George Henslow and Mr. J. Douglas, and they have reported to the Council of the Royal Horticultural Society as follows:

We beg leave to report that we have examined the papers submitted to us—in all 184. Of these we selected 89 as worthy to be placed in the first class, 55 in the second, and 28 in the third. The remainder, 12, are not placed; the number of marks attained being below 100. These results are most encouraging. Speaking generally, the answers are extremely well done. The information is accurate upon the whole, and the subject-matter well expressed. Perhaps the practical horticulture showed, as might be anticipated, a slight superiority over the elementary principles.

**A VARIEGATED PLANE.**—Mr. J. Russell, nurserymen, Richmond, obtained a first-class certificate last week for a beautifully variegated variety of *Platanus acerifolia*. It was shown and certificated under the name of *P. occidentalis argentea variegata*. The young leaves when fully developed are colored a clear creamy white, or striped and flaked with that color on a green ground. Ultimately they become wholly green, so that a plant in good condition is clothed with rich green leaves, and on the young shoots either white or variegated leaves, so that at a short distance off the plant appears to be in flower. Mr. Russell says his plant is a seedling sport which originated in his nursery. It appears to be identical with *P. acerifolia*, var. *Süttneri*, which has been known and grown for at least twelve years at Kew. There used to be two large trees, said to be fifty years old, of a variegated Oriental Plane in the public park at Buda-Pesth. As grown in Mr. Russell's nursery, where the plants are perfect pyramids six feet high, this Plane is most ornamental.

**PLAGIANTHUS LYALLII.**—This beautiful New Zealand shrub is flowering freely at Kew this year, where it is grown against an east wall and also in the open border, the latter position being most favorable this season, probably because of the mildness of the past winter. It has thin twiggy branches, ovate cordate dark green leaves and numerous axillary clusters of pure white flowers each an inch across, and borne on a long, slender, drooping pedicel, in effect not unlike the double Cherry. Under glass we have never succeeded in flowering this plant. It appears to require a sunny, airy position sheltered from cold winds and severe frosts in winter.

London.

W. Watson.

The wild shrubs which skirt the waysides have a beauty beyond that of the cultivated exotics in spaded gardens; they cover the nakedness of stone walls with foliage and flowers; they give shelter to the birds and fruit for them, which is also a luxury to the children; they protect adjacent farm lands from winds and constitute the most interesting embellishment of a rustic farm.—*Wilson Flagg*.

## New or Little-known Plants.

### A New Hickory—*Hicoria pallida*.

**I**N its relation to the other Hickories, *Hicoria pallida* is nearer to the Nutmeg Hickory than to any other, but while the Nutmeg Hickory, *Hicoria myristicæformis*, has many characters which ally it to the Pecan and Bitternuts, this has characters which show close affinity to the White Hickory. The sterile flowers of *Hicoria pallida* are only from the base of the shoot of the year, while in the Nutmeg Hickory they are from separate lateral buds as well. There are in both seven or nine rather small ovate-lanceolate leaflets which are covered on their lower surface with silvery peltate scales. In *Hicoria pallida* these scales are also found on the sterile inflorescence, covering the peduncles, bracts and calyx-lobes, on the young twigs and on the petioles, and this in the early spring gives a brilliancy to the foliage when the sunlight falls upon it that renders it very conspicuous. Although these scales are persistent on the leaves they become dulled and lose their lustre by the middle of summer. Covering the buds and young fruit and mixed with the scales on the lower surface of the leaves are resinous globules similar to those which occur on *Hicoria alba*, and which render the young foliage of that tree so fragrant. The divisions of the calyx of the pistillate flower which subtend the very large stigmatic lobes are broad and covered beneath with tufts of purplish hairs, the young fruit being like that of *Hicoria minima*, but larger. The petiole is covered with tufts of coarse yellow or brownish hairs, which add greatly to the resemblance between the foliage of this tree and that of the White Hickory, as both have about the same number of leaflets; those of the White Hickory, however, are somewhat larger and are a lighter and a brighter green.

The twigs, which are even more slender than in most forms of the Pignut, are purplish brown in color, marked with few oblong, light gray, but rather inconspicuous lenticels, and are usually smooth, although some collected in southwestern Georgia are tomentose toward the tip around the base of the terminal buds. The oval buds are sharply pointed, and are borne on an evident stipe; the lateral buds are similar to the terminal in shape and general appearance, but are somewhat smaller. The terminal are enfolded in from six to nine imbricate scales, and the lateral in from five to seven; while the number of scales in the terminal bud of the Nutmeg Hickory seldom exceeds five or six, and in the lateral bud four. Although the scales are imbricate, they lengthen but little in exfoliation. The outer are nearly glabrous on the back, but the inner are covered with a close fine pubescence. Sometimes there are coarse tufts of hair on either side of the midrib of the leaflets, but this is not always the case; whenever present it is persistent.

The fruit, as in most of the Hickories, varies much in shape and size, being sometimes almost globular, and again nearly pear-shaped, frequently assimilating forms of the Pignut or White Hickory. The usual form is subglobose, with a nut of nearly the same shape, barely apiculate at the bottom and subcordate at the top. The husk in this form is thin, less than one inch thick, and splits nearly or quite to the bottom, freeing the nut, or remains on the tree until the middle of winter without splitting at all. Another form resembles closely the pyriform fruit of the Pignut, the thin and indehiscent husk prolonged at base into a slender apophysis. The nut of this form is oblong, nearly circular in cross-section and mucronate at the base. It is seldom found over three-fourths of an inch long, and is not at all angled. In another form the fruit is nearly globular; the husk is over one-eighth of an inch thick and is wing-margined along the sutures. The nut is laterally flattened, angled, sharply pointed at both ends, and is about 1.5 inches long. The nuts of the last form resemble those of

W.W. ASHIE, Del.

Fig. 39.—*Hicoria pallida*.—See page 304.

1. Fruiting twig of a typical nine-leaved form of *H. pallida*, natural size.
2. Flowering twig, showing fertile and sterile flowers and persistent bud-scales, natural size.
3. Calyx of sterile flower, enlarged.
4. Anther, enlarged.
5. A nut-form peculiar to *H. pallida*, natural size.

6. Nut split at the commissure, natural size.
- 7 and 8. Nut-form which approaches that of *H. glabra*, natural size.
- 9, 10 and 11. Nut-form which approaches that of *H. alba*, natural size.
12. Tip of twig showing winter-buds, natural size.
13. A peltate scale-scuri, magnified about twenty-five diam.

the White Hickory, and are the least common. All the nuts are white or yellowish in color, have thick hard shells and are four-celled at the base.

From its habit *Hicoria pallida* might be called the "Black Jack" of the Hickories, for it seldom exceeds forty feet in height, and is often not over eighteen or twenty, with a proportional trunk diameter of from eight to fifteen inches. The very slender upper branches are erect and closely crowded, forming a narrow, oblong crown; but the lower ones droop so low that on isolated trees their extremities are only a few feet above the ground. The trunk, too, is always short, even when the tree is growing under the most favorable conditions, most of the branches spreading from a point only fifteen or twenty feet above the foot of the trunk.

The gray bark is thick and firm, with deep and rather broad fissures separated by broad, irregularly anastomosing ridges, its general appearance being like that of the White Hickory, but rougher. In the summer, when in foliage, it bears a close resemblance to the White Hickory in all the characters which a coup d'œil can gather; in the winter the slender twigs make it more nearly resemble the Pignut. The heart-wood is brown in color; the sap-wood nearly white; and I was told by persons who had used the wood that while much inferior to the White Hickory in those properties that make good hickory, it is equally as good as that of the Bitternut. The tree, however, is too small and too infrequent to be of importance economically.

Even in the mountains of North Carolina, where I have found *Hicoria pallida* most common, it is exceedingly local, occurring at widely separated places and seldom more than a dozen trees being found at the same station. It prefers a poor, dry, soil; and I have usually found it on sandy soils, although not always.

In the mountains of Virginia and North Carolina it is associated with the Red Oak, the Rock Chestnut Oak, the Pignut and White Hickory, and ascends in the mountains of North Carolina as high as 4,000 feet above sea-level. In south-western Georgia it is found growing with the White Hickory, Post Oak, Dogwood and Long-leaved Pine on a good, loamy soil underlaid with marl and limestone. In eastern North Carolina it is found on the littoral sand dunes at Wilmington, growing with the Sand Oak, *Quercus Catesbæi*, the Spanish Oak and the Red Cedar; while near by are the Water Oak, Live Oak, Laurel Oak and Bays. On the sandstone ridges of central Tennessee it occurs with the Scrub Pine, Chestnut, and with the Oak and Rock Chestnut Oak.

Its distribution, so far as I have observed, is from southern Virginia and eastern North Carolina to middle Tennessee and south-western Georgia; but it is probably more extensively distributed and should be looked for in eastern Kentucky and northern Alabama.

This tree was first distinguished in the spring of 1895 near Chapel Hill, North Carolina, where, after two seasons' search, I have been able to locate only three specimens. The summer after distinguishing it at Chapel Hill, while examining on horseback the forests of the western portion of North Carolina in the preparation of the description of the woodland of North Carolina in Bulletin No. 6 of the North Carolina Geological Survey, I found this tree in several other places in that state. The following spring it was found in south-western Georgia and eastern North Carolina, and more recently in Tennessee. Having no good description of the Nutmeg Hickory or specimen for comparison for a long time, I considered *Hicoria pallida* to be that species, or at most a variety of it. The Nutmeg Hickory, however, does not occur in North Carolina, although indirectly credited to this state in the recently published *Nomenclature of the Arborescent Flora of the United States*.

From what is now known of it *Hicoria pallida* seems to be another localized, south Appalachian species.

North Carolina Geological Survey.

William Willard Ashe.

## Cultural Department.

### Border Plants.

**RUDBECKIA TRILOBA**, var. *Golden Glow*, is now in bloom. It is a questionable acquisition. The color is not nearly as bright as that of our double *Helianthus multiflorus*, nor is the flower as finely formed. The single form of this *Rudbeckia* is handsomer, with a ray of yellow florets and a black disk. Compared with the Sunflower, it makes a much better border plant, as it is perfectly hardy, stiff in habit and stands without stakes and has handsomely cut foliage.

Hybrid *Montbretias* are acceptable hardy plants. They are usually treated in the same way as *Gladiolus*, and the corms lifted and stored dry during winter. With no thought that they would prove hardy, a batch was left out under cover of a few leaves and Pine branches; these plants are more vigorous than those from lifted corms and bloom earlier. Just now their gracefully arching, compound spikes of scarlet and yellow flowers form part of an attractive picture, with dwarf Sunflowers for a background and *Heliotrope* for the front. Probably the late-flowering *Hemerocallis Thunbergii* could be used in place of the Sunflower with better effect. *H. fulva* in the border becomes a weed sometimes, but properly used among shrubs it is a striking plant, handsome in foliage as well as flower.

Among a number of seedling *Carnations* we found one with perfectly formed white flowers on long stiff stems. It came among seedlings of *Mrs. Fisher*, a standard florists' variety of the tree or perpetual type, but, as often happens, this variety had reverted to the border type, and for winter flowering it was useless. Pippings put in during the late summer, when rooted, boxed off and wintered in a cold frame, according to the English practice, and planted out in spring, make neat plants and bloom finely, earlier than standard varieties rooted in the winter. It is complained that we have no border varieties to compare with such as are grown on the other side, but I think if our florists who raise new varieties would save some of the reverted types, and prove them, we might get together a collection embracing all the colors.

*Lobelia fulgens*, var. *Victoria*, is an admirable border plant for the autumn garden. It will be strikingly effective in a week or two when the *Phloxes* are gone and golden colors predominate in the borders. It is remarkable for fine dark foliage and brilliant scarlet flowers. Besides being an unusually attractive border plant, *Campanula grandiflora* has the good quality of coming into bloom when nearly all other kinds are past. The variety *Mariesi* is probably the best of all, and, with its white form neatly blended, will continue for a long time. This *Campanula* is also an excellent plant for the rock garden, where now and then a taller plant varies what would otherwise be a monotonous carpet of low plants. They sow themselves quite freely. *Pentstemons* from seed will soon be in bloom. Those from cuttings from a few selected plants rooted last winter have been flowering for the past three weeks. They add variety at a time when the borders begin to look bare; besides, a stock of young plants in spring-time comes in handy to fill occasional bare spots.

Old plants of *Pyrethrum roseum* hybrids bloom sparingly now, and a batch of seedlings raised in winter are just coming into bloom. They will be mostly single, but showy, as bright colors prevail. *Erigeron speciosus*, with purple Aster-like flowers, is very bright. In our warm sunny climate the plant frequently exhausts itself in bloom, and should be treated as a biennial. It is easy to keep up a supply, as seeds ripen and germinate freely. In fact, it is not uncommon to find numbers of self-sown seedlings come up in the vicinity of old plants every spring. *Hypericum aureum* is a good low-growing shrubby American species. It is an excellent plant for the foreground of the mixed border where herbaceous plants are used. It is quite stiff in habit, and its flowers occur in bunches near the ends of all the branches. *Delphinium Sinense* has a much longer season of bloom than hybrids of *D. elatum*. Its deeply tinted blue flowers are scarcely equaled in intensity. *Dicentra formosa* lasts a long time in bloom, and a shady position suits it best. Here we have it behind a large rock, and it does equally well in the shade of trees if moisture enough is supplied. The delicately cut glaucous foliage and arching scapes of pink flowers resemble those of *Scilla campanulata rosea*, and contrast beautifully.

*Malva moschata* is exceedingly free; in fact, flowers on to exhaustion, and should be cut back when it begins to form seeds. Pink and white saucer-shaped blooms are produced in succession on short stems from the axils of the leaves. *Linaria Dalmatica*, a rather new Toadflax, with glaucous leaves and

comparatively large flowers, is not as ornamental as our roadside Butter and Eggs, *L. vulgaris*, but has the good quality of being a perennial. Masses of *Monarda didyma* are effective and sure to please those who want a border plant which will take care of itself. The whorls of red labiate flowers come near the tops of the stems and give the appearance of heads of bloom. It needs watching, or it will crowd other plants. The majestic *Veronica longifolia subsessilis*, where it succeeds, is a splendid border plant. It delights in a good deep soil, and in a situation where it is fully exposed will grow four feet high. It is the finest of all the Speedwells and the latest to bloom. *Hydrangea radiata* has little in outward appearance to suggest relation to any other Hydrangeas we know. It is sub-herbaceous, sending stout stems up every spring clothed with blue-green ovate leaves, downy beneath, and terminated with large flat corymbs of fertile flowers. Here and there a sterile flower may be noticed, but there are not enough of these to attract attention. In appearance the flowers resemble those of the common Elder. Here also is the true *H. paniculata*, a much stouter plant than the variety *Grandiflora* commonly seen. The light graceful panicles of the species are a relief, for it must be confessed that the big lumpy heads of the variety *Grandiflora* become a trifle wearisome in the late season, since they display themselves in almost every door-yard, although a large and well-grown plant is very showy when it stands alone with plenty of room.

Wellesley, Mass.

T. D. Hatfield.

### Herbaceous Perennial Plants in Flower.

**L**ATHYRUS LATIFOLIUS, or the Everlasting Pea, should have a place in every garden where herbaceous perennials are grown. The typical plant is not as showy as some improved forms found in cultivation. Those grown here and in blossom now reach a height of five or six feet in a medium rich soil and open position. When the plants are about a foot high a few loose branches should be set about them to clamber upon. Grown in this way the flowers are produced for many weeks. These are of a dark rose color and borne in clusters of about twelve on long peduncles which measure six or nine inches in length. The variety *albus* makes a good companion, as it is similar in all its parts, but it has flowers which are of a white so pure that it may be called dazzling. The white-flowered form is rather more difficult to keep than the type, but both are invaluable for cutting purposes.

In the front row of the herbaceous border where the soil is light and in a sunny position, *Stokesia cyanea* proves itself one of the best of the showy composites of the season. It is slightly above a foot in height, branched, and the branches are terminated with bright blue flower-heads not unlike Chinese Asters. Although it is sometimes considered not quite hardy in this locality, there are plants in this garden which have been grown successfully in the borders for several years, probably because the situation and exposure are just suited to their needs.

The Wall Germander, *Teucrium Chamædrys*, is completely covered with its reddish purple flowers and makes an excellent plant for a dry, sunny position, either in the rock garden or the front row of the herbaceous border. Its flowers are produced in leafy terminal spikes and the individual flowers measure about three-fourths of an inch in length. The stems are six or eight inches high and rise from a creeping root-stock. This compact, dwarf, showy perennial comes from Europe and is quite hardy here and well worth extended cultivation. Another species of Germander grown here for some years is also worthy of notice for its showy flowers. It is known as *Teucrium Hyrcanicum*, and, although introduced into cultivation from Persia as long ago as 1763, is but little known in America. In the border the plants become twelve or fifteen inches high, and the stems are clad with ovate-cordate deeply crenated, slightly pubescent leaves. The purple flowers are in dense spikes about six inches long, and a plant with a dozen spikes or more is pleasing and effective. It enjoys a light warm soil in a sunny position. Our plants were raised from seed four years ago and have proved quite hardy without any protection in winter.

Of a large number of species of Mullein grown here the best and most satisfactory perennial among them is *Verbascum nigrum*. Another good perennial, which, however, cannot be relied upon to flower every year, is *V. Olympicum*. If this species would flower as freely as some of the other kinds it would hold first rank, and, indeed, few perennials would compare with it. On the other hand, *V. nigrum* is an exceedingly floriferous plant, and is almost constantly in flower from July until frosts destroy the blossoms. It grows about four feet high and the stems are clothed with long cordate leaves. The flowers are produced in branched racemes; the corollas are

yellow and the filaments of the stamens are covered with bright purple hairs. It grows well in any good garden soil, but does best in an open sunny position.

The Japan form of *Veronica Virginica*, which we have grown from seed obtained from the Kew Gardens two years ago, proves itself, with longer acquaintance, to be an excellent perennial. Last year the plants did not grow as tall as the type plant, our native species, but this season they are quite as tall and as vigorous. The main difference is in the time of blossoming, and the Japanese form is five or six weeks earlier than our North American plant. The best blue Veronicas now in blossom are *V. longifolia* and some of its varieties.

A large mass of Oswego Tea, *Monarda didyma*, is ornamental and effective grown on the lawn. The bright scarlet flowers are produced in whorls on the ends of the stems, which are about a foot and a half high. The Wild Bergamot, *Monarda fistulosa*, and some of its varieties make good border plants when grown in large clumps. The flowers of this species are purple and the stems grow slightly taller than those of *M. didyma*. *M. Bradburyana* is the neatest and most compact plant in the genus for gardening purposes. The stems are about a foot in height, terminated with pink flowers and reddish bracts. The *Monardas* are thrifty plants, increasing rapidly, and their flowering season is of long duration.

A few weeks ago, in the back row of the herbaceous border, large well-established plants of *Clematis recta* were loaded with white flowers. This plant is the best of the upright Clematises. It is an excellent hardy perennial, growing freely in almost any ordinary soil or situation, and is but little troubled with insects. There are a number of varieties of this species, and all are desirable garden plants. The reason for writing about it now is to recommend a late-flowering variety grown here, and known as *C. recta*, var. *umbellata*. It differs from the typical plant in having longer and narrower leaves, and its season of blossoming is two or three weeks later, thus giving us a longer blooming season of this desirable *Clematis*. *C. recta* and its varieties do best if not disturbed often. My experience with them is that after being disturbed they do not grow so strong or attain their ordinary height until the second year after transplanting.

*Campanula persicifolia* is an old-fashioned plant with blue flowers, but there are few new perennials that can compare with it, and it should be included in every collection of hardy herbaceous plants. There are numerous varieties, and that named *Alba grandiflora* is particularly floriferous and makes a fine display. If the flower-stems of this *Campanula* are left on the plants after they have blossomed in early summer they will produce a fairly good second crop. Our plants are now blossoming for the second time this season.

If mixed borders are backed up by shrubs, *Bocconia cordata* is effective in such a position. The individual white flowers are not very striking nor handsome, but the large terminal panicles are always effective. This Japanese plant grows with the greatest freedom and increases rapidly. The stems reach to a height of six or eight feet and are thickly set with large glaucous leaves. The desirable *Pentstemon barbatus*, var. *Torreyi*, has done remarkably well this summer. Its long, wand-like inflorescences are graceful, and the bright scarlet color of the flowers always attracts attention.

Harvard Botanic Garden, Cambridge, Mass.

Robert Cameron.

### Hybridizing Caladiums.

**A**MONG the fancy-leaved Caladiums there are several varieties that are constituted so as to endure the full sunshine all day long, but most of them lack the bright coloring which gives these plants their value. The leaves are for the most part green, as, for example, *C. Wightii*, *C. Duchartrei* and *Queen Victoria*. There are a few brilliant-colored ones which do almost as well in the sun as the green kinds; three of the best are *Rossinii*, *Perle de l'Exposition* and *Uranus*, but the great majority of the showy kinds are not suited for outdoor decoration.

Some of those kinds which have done best out-of-doors for the last few years were set apart at the beginning of the season for hybridizing purposes in order to see if by crossing them a greater variety of color can be had. The operation has been a successful one so far as it has gone, and as it is exceedingly simple, a description of it might interest some fanciers of these plants. The tubers, as a rule, send up their flowers shortly after they are started into growth in the spring; large-sized tubers are very apt to flower after the first leaf is developed. The flowers are arranged on a spadix; the stamens occupy the upper portion which, when shedding their pollen, are exposed to view, but the ovaries, which occupy the lower

part of the spadix, are concealed from view by the lower half of the spathe, which is usually contracted near the middle, forming a tightly closed little chamber over the seed-bearing part. The female organs arrive at maturity in advance of the males on the same spadix by several days; there is, therefore, little danger of self-fertilization. In order to have access to the pistils it is necessary to cut an opening through the walls of the little chamber. The proper time to do this can only be judged by the size of the spathe, but if the stigmas are not ready for the pollen a delay of a day or two makes little difference, as the perfect condition of the stigmas is indicated by a viscid substance covering them. The pollen is at its best for transferring easily in the forenoon, say from ten to twelve o'clock, and at that hour, having selected the pollen-bearer, nip off the entire inflorescence. This must be done carefully, as the pollen falls off at the slightest touch, and therefore, before nipping it off, incline it so that the pollen will fall into the cavity formed by the upper part of the spathe. Then with a camel's-hair brush convey a little of the pollen to each of the stigmas, and after this is done tie up the inflorescence to a support, so that with increased weight when the seeds are ripening it will not fall over the side of the pot and break off. A hanging label is affixed with the names of both seed and pollen bearing parents. The seed is ripe in from two to three weeks; it is quite small, yellowish-white in color, and germinates in shallow pans well drained and filled to within an inch of the rim with a mixture of loam and sphagnum in equal parts rubbed through a fine sieve. The seeds were barely covered and pieces of glass were kept on during the warm part of the day to prevent a too rapid drying out. In a few days the seed leaves appear, and at this stage they look to any one not familiar with seedling *Caladiums* like young turnips, each one having a cotyledon missing. The first true leaf, however, shows the identity of the plant, although it is a trifle rounded. It is green in color, as is also the second leaf, the third showing the first indications of other colors. This occurs invariably in the middle of the leaf, being either white or dull red. This is the stage in which the seedlings are at present; they are growing in thumb-pots, three in each pot, and are a healthy-looking lot.

Botanic Garden, Washington, D. C.

G. W. Oliver.

### Notes on Flowering Plants.

**F**ORTUNATELY for the grower, few gardening operations are pressing in midsummer if the work of the early months of the year has been done systematically. But at all times success depends largely on attention to details, and some of these must be seen to now. Plants of different kinds to furnish flowers for cutting in winter are essential on a private place, and considerable management must be exercised to find room for sufficient stock in the limited space usually at command.

Roses in pots and boxes out-of-doors in preparation for winter-forcing are still growing freely, and with the abundant rains we have had in this section are likely to grow for some time to come, for it will take a considerable time to harden and ripen this sappy growth. Carnations grown out-of-doors are also liable to suffer somewhat from too much moisture, for the growth is soft and naturally more open to fungoid attacks. The plants should be closely inspected when they are being replanted under glass about a month hence. In a changeable season such as this has been the practice of growing Carnations under glass throughout the year is likely to prove the most satisfactory.

Bouvardias for cut flowers have often been deservedly noted in GARDEN AND FOREST. The chief point in their care at this season is the frequent pinching to develop a bushy habit; the time for the last pinching depends upon the season when it is desired to have them in bloom. Planting out in a rather sandy but rich soil is decidedly better for Bouvardias than pot culture, and results in much larger and stronger plants. There is also less trouble from red spiders and other insects. But as these plants are susceptible to cold they should be brought under cover early, usually not later than the 15th of September in this locality.

Cytisus and Acacias should now be making sturdy growth outdoors in the full sunshine. They enjoy bountiful watering during bright weather, but free drainage of the pots is necessary, for all plants of this character are impatient of stagnant water at the roots. The same treatment applies to Azalea Indica, which should be plunged in coal ashes or other cool material for the protection of the tender roots, and have full sunshine to ripen the growth and an abundance of water to perfect the flower-buds. Peat and leaf-mold are no longer

considered absolutely necessary as the main part of the compost for Azaleas, so that the cost of such material and the difficulty of securing it need not deter any one from attempting their cultivation. Admirable specimens have been grown in a good fibrous loam. Chorozemas, Cestrum and Reinwardtias should be included in stock useful for conservatory decoration and for cutting during winter and spring, and all of these may be grown to advantage out-of-doors through the summer. The growth thus made is short-jointed and better ripened than that of plants kept under glass the whole season. *Stevia serratifolia* and one or two of the *Eupatoriums*, notably *E. riparium* and *E. triste*, are also useful for cut flowers and require but little care. Spring-rooted cuttings potted on before the growth became stunted and finally shifted into six-inch pots are of convenient size, and after the main crop of bloom has been cut the old plants may be thrown away to make room for other plants. Plenty of water and frequent pinching to induce compact growth are the main requirements for *Stevia* and *Eupatorium*, and when the plants are plunged out-of-doors the pots should be twisted around once a week to break off any roots that push through the bottom.

Mr. Orpet's note about Poinsettias in a recent issue is plain and practical. I heartily agree with his method of outdoor cultivation, which produces much more stocky plants and of stronger constitution than those grown under glass continuously. *Euphorbia Jacquinæflora* may be grown in the same way, but as this plant seems to suffer from indigestion at times, and often fails suddenly, it is probably safer to keep it indoors.

Begonias for winter cutting, of which *B. incarnata*, *B. Saundersii*, *B. rubra* and *B. nitida* are among the most useful, should be grown on in pots from spring cuttings unless a short section of bench can be spared for planting them out. The latter plan has the advantage in producing a greater quantity of bloom from a given number of plants.

Bulbs of *Lilium Harrisii* are already in the market, but the first consignments are not always the best, and unless New Year blooms are desired, it is preferable to wait a little longer for the bulbs. In any case they should be potted as soon as received, for these bulbs suffer from long exposure to the air.

#### Wintering Hardy Plants in Vermont.

To the Editor of GARDEN AND FOREST:

Sir,—The last winter was a good one for testing the relative hardiness of all kinds of plant-life in Vermont. As a rule the coldest weather here is preceded by snow, so that the ground is well protected from the lowest degrees of cold. But last winter the coldest weather came with bare ground and it was frozen to a great depth. Many plants that had been wintered here in good condition in former years were entirely killed, while others not killed outright were so put back as to require a full season in which to recover their former strength. Many of the more tender Lilies were entirely killed when not situated in sheltered places or protected, and others which were not killed outright were so injured that the blight soon finished them. The outer scales of the bulbs of *L. auratum* were so frozen as to become rotten when thawed out in spring, and though the shoots came up and at first appeared strong as usual, they were early attacked by blight or some disease and soon succumbed. Bulbs of *L. longiflorum* and its varieties were generally killed outright, and those of *L. speciosum* were also killed where exposed to the coldest winds. In sheltered places or where covered with a mulch this species did not suffer. Our native Lilies, like *L. Canadense* and *L. superbum*, are usually among the first to be attacked with blight, except *L. candidum* and *L. excelsum*, which with me have been the first to show it. But I have noticed this year that the hardier kinds, like *L. tigrinum*, *L. Canadense*, *L. superbum*, etc., have shown almost no blight, while others more tender, which in former years have been comparatively free from it, have suffered more. It is natural to conclude that the reason for this is largely due to the injury from severe cold. I am glad to state that the *L. Henryi* has proved not only quite hardy, but remarkably free from blight, and may be counted as one of the most reliable hardy Lilies. None of the Tiger varieties have shown more vigor than this.

*Lilium Kramerii*, which has been wintered in the ground in previous years, was wintered in soil in the cellar. It had usually been so injured by the fall rains that we tried this method, which has been a great success, for not only did nearly every bulb come through in perfect condition, but

almost all have bloomed and been much freer from blight than usual. I shall hereafter winter this bulb in this way.

Among the hardy plants *Anchusa Italica* was entirely killed where not well covered; and such species as *Bocconia cordata*, *Coronilla varia* and *Lathyrus latifolius*, Perennial Pea, were killed to a considerable depth, and though they have finally come up from a lower portion of their roots they are not of their usual size or strength. *Bocconia* was entirely killed to the depth of a foot. Below this the root had life and has come up. *Coronilla*, though a little quicker in recovering, was killed to about the same depth. *Hibiscus Moscheutos* in moist places was killed outright; in drier soil young plants survived. *Cassia Marilandica* in moist ground stood the weather, but in the same rows on a little higher ground was killed. *Aletris farinosa* was entirely killed. The upper portion of many of the roots of *Asclepias tuberosa* were killed, and though they generally come up from below they were very backward. *Bellis perennis*, which had been wintered here in previous years, though well covered, was entirely killed. *Helianthus Maximiliani* has wintered well heretofore, but not a plant has come up this season. *Helleborus purpurascens*, which had wintered in perfect order for two seasons, was about all killed, as was *H. niger*. The double Hollyhocks, as a rule, though well protected, were killed. The hardier sorts of Foxglove, such as *Digitalis grandiflora* and *D. Sibirica*, which had always been considered perfectly hardy here and which had established themselves in strong clumps well protected with a good growth of their thick leaves, were generally killed.

*Ligustrum Ibo* has wintered here previously in good condition, but was killed outright last winter. Only now and then a plant has sprouted at all from the root. The California Privet was also badly killed back in its branches and is not so strong or promising as a year ago. The common Privet, *L. vulgare*, came through pretty well and shows little damage.

Charlotte, Vt.

F. H. Horsford.

### A Plea for Zinnias.

To the Editor of GARDEN AND FOREST:

Sir,—This year my garden is without Zinnias, and their absence convinces me of their usefulness. They deserve a place in the shrubbery, where they furnish an embroidery of color during the season when few shrubs are in flower. But their chief usefulness is to furnish cut flowers from late July until frost. One hardly appreciates their range of color until one has had a large stock of them to draw upon for floral arrangements during the season. Besides the common orange-scarlet group, a packet of good mixed seed will give rosy scarlet and salmon-scarlet of different depths, almost pure orange, yellow, straw-color, deep crimson, rose, exquisitely pure pink, flesh-color and several light tints that a little child has defined as "dark white," and which, perhaps, may best be described as ivory, pale lemon and greenish white, some flowers of the latter tint being almost pure white, so that a light tone is found that will harmonize with any of the color divisions.

With such a stock of Zinnias to cut from there is always at hand the necessary basis for a bouquet, for it only needs two or three spikes of *Gladioli* in harmonizing tints, some sprays or trails of any one of the small-flowered *Clematises* or of the Cinnamon Vine, or heads of *Gypsophila paniculata*, to make an attractive and often a distinctly beautiful bouquet in any one of at least three colorings. These hardy flowers are usually available, and if the arrangement is varied by the introduction of a stalk of splendid Tiger Lilies, two or three great Golden-banded Lilies, half a dozen flowers of *Lilium speciosum*, either white or rose; Dahlias of various colors, a few belated spikes of Delphinium or some purple bells of *Cobæa scandens*, or if in an arrangement of yellow tones, a cluster of snowy Day Lilies or some sprays of showy *Salvia splendens* are added it will be seen that a succession of extremely effective bouquets will have been evolved from rather meagre materials. For throughout the three months or more that these supplemental flowers are coming into flower the Zinnias will steadily supply the foundation for the series.

### Recent Publications.

*The Principles of Fruit-growing.* By L. H. Bailey. The Macmillan Co. New York.

Professor Bailey has been preparing a monograph on the Apple, and in the course of his work it became clear that many of the essentials of the science and art of

pomology could be grouped together so as to be applicable to all kinds of fruits, and this volume is the result. Its range and purpose, therefore, is precisely defined by its title. It is a discussion of the principles which underlie the successful production of all kinds of orchard fruits, and, indeed, most of the small fruits. Probably there is more fruit consumed in the United States than in any other country of the temperate zone, and the desire for fruit is still rapidly increasing. Neither is there any country in the world where fruit is produced in such abundance, variety and excellence, and yet it is probable that fruit, in spite of an increasing demand, will grow cheaper rather than dearer. It would seem impossible that grapes, for example, can be raised profitably for a price lower than the present average, and yet in growing all kinds of fruit there must be a constant effort not only to lessen the cost of production, but to improve the quality of the product. This book is an attempt, not only to establish the laws which must be followed if the best fruit is to be grown at paying prices, but it explains the limitations of climate and of location, which make fruit-growing a hopeful industry in one region and a doubtful one in another. The study of the geography of a fruit farm with reference to markets, to threatened frosts and the conditions which make them dangerous, to winds and air currents, to atmospheric drainage and other physical conditions, is full and, of course, instructive. Equally important is the chapter on the evolution of tillage, in which such subjects as the texture of the soil—that is, its physical condition, as distinct from the amount of plant-food it contains—are treated, together with all the operations necessary for the conservation of moisture, even down to minutiae of detail. Of course, all the elementary facts which it is necessary for a fruit grower to know in relation to diseases and insects are clearly set forth, and we are glad to see that a most interesting bulletin of the Cornell Experiment Station on the general subject of spraying is largely incorporated into this chapter. Points of practice, like the laying out of grounds, the selection and setting of trees, choice of varieties, the proper methods of fertilization, with the latest methods of harvesting and marketing, are given with clearness and precision. Altogether, this is one of the best numbers of the admirable Rural Science Series, of which Professor Bailey is the general editor. Books like this go far to remove the reproach that there are no available manuals for the farm and garden in America which are at once practical in their directions and thoroughly scientific in their methods.

### Notes.

Six steamers from Central America landed 115,800 bunches of bananas at this port during last week.

A correspondent of *The Gardeners' Chronicle* writes of a Scotch Pine not far from Southampton with a stem clean and handsome and measuring thirteen feet in circumference four feet from the ground. The trunk is as round as a ship's mast, and does not divide until forty feet from the ground, when it is capped by a fine round head.

At a special meeting of the New York Gardeners' Society the prizes awarded at the June exposition in the City Hall were distributed. It was decided to hold an exhibition of Cannas and other flowers in connection with the annual dinner of the society on the second Saturday of September, and to hold a Chrysanthemum show in November. Some good seedling Cannas, raised by Mr. A. L. Marshall, of Pawling, were exhibited, and one of them, a large deep crimson flower, named John B. Dutcher, received the society's certificate.

In the first volume of GARDEN AND FOREST (page 499) we gave an excellent illustration of a fruiting branch of *Elæagnus longipes*, and in the descriptive note accompanying it stated that the shrub was well worth growing "for the beauty of its fruit alone, which, moreover, is juicy and edible, with a sharp, rather pungent, agreeable flavor." We also suggested that the quality and size of the fruit might be improved by selection and become a highly esteemed dessert and culinary fruit.

We do not know that any persistent efforts have been made in this direction, but every year confirms our original belief as to its value. The shrub almost invariably yields a full crop early in July in this latitude, and its mild acid flavor is agreeable to almost every one. Indeed, many persons prefer it to the currant.

Among the choicest grapes from eastern states now seen are Delawares, and Niagaras from North Carolina; Champion, Ives and Moore's Early also come in southern shipments. Apricots in five-pound baskets are coming from the interior of this state, and Chelsea plums, in eight-pound packages, from North Carolina. Le Conte, Keiffer, Bell and Catherine are among the pears received from neighboring states. Watermelons, from Virginia and the Carolinas, and muskmelons, from Maryland, Virginia and North Carolina, are plentiful.

The current number of *Science* contains an article by Professor Bradley M. Davis describing types of plant-life in the hot springs of Yellowstone Park, and explaining in an interesting way how this minute vegetation helps to build up the deposits of various crystals. Not only do these algæ aid in forming rocks, but the most beautiful sculpturing and coloring of the Mammoth Hot Springs, the peculiarities of the columns and moldings and the capitals, as well as the rich browns, olives, oranges and greens with which they are painted, are all directly due to the presence of these plants.

*Lilium Henryi*, which was discovered a few years ago by Dr. Henry in China, has been called the orange Speciosum, but really the Chinese Lily is a nobler plant, much more graceful, and only resembles *L. speciosum* in the form of its flower. Mr. A. Herrington has sent to this office a spike from Mr. Twombly's place in Madison, which is five feet high, although it is from a bulb planted last autumn. The stalk is covered with leaves throughout its entire length, and the poise of the flowers at the ends of their long slender stems gives the plant a most elegant and distinguished air.

The leading cut flowers on the street stands now are China asters and gladioli, since sweet peas have passed their prime and are rather short-stemmed. Coreopsis continues to furnish good flowers, as it has done all the summer through, being really one of the very best of plants for the production of yellow flowers. Tuberoses, once the most popular of street flowers, is again occasionally seen, and seems to be growing in popularity on the east side of the town. Of course, there are always carnations and mignonette, but at no other season do the stands of the sidewalk venders show so little variety as they now do.

Seventy-six carloads of California fruits received here last week included one car of selected Valencia oranges, an unusually late shipment of this fruit. Nectarines are among the scarcer fruits from the west. Bartlett, Souvenir du Congrès, Beurre Clairgeau, Duchess and Clapp's Favorites comprise the pears in season, and the first Flame Tokay, Chasselas de Fontainebleau or Sweetwater, White Muscat of Alexandria and Thompson Seedling grapes are now offered. Bartlett pears are especially good this year, and 21,300 boxes of this fruit were sold here last week, with 17,000 boxes of peaches and 19,700 crates of plums.

The food markets of the foreign colonies have a unique interest among the more uncommon phases of life in American cities. In our own city, on turning into the foot of Mulberry Street, off the Bowery, a complete change of scene is at once realized, especially on Saturday morning. Except from children on the streets or in the popular little Mulberry Bend park, no English word is heard, and besides now and then a Chinese laundryman bent on buying some bunch onions at a close bargain, Italians only are seen. Even the experienced New York produce dealer would here find new and strange vegetables, not to speak of bread and cheese and meat in surprising shapes and sizes and colors. At this season popular favor of the buyers seems to rest with greens for salads, onions, sweet peppers, tomatoes, the unfamiliar fruits of many cucurbitaceous plants and string-beans in the order named. There are strap-leaved lettuces, true chicory leaves tied in bunches, not the endive which is usually sold here under that name, enormous leaves of Swiss chards, bunches of celery tops and of strong plants of dandelion with coarse leaves more than a foot long, tender young plants of aromatic fennel with finely dissected leaves, fresh Bee Balm, creeping thyme, marjoram, hyssop and many other unidentified plants of the Mint family. Stems of our common Mallow, with their leaves and cheeses, are recommended by the venders for infantile stomach pains. Among odd forms of the cabbage family are

stalks of cauliflower fifteen inches long, and sold for eight cents a bunch. The crinkled Savoy cabbage is much in evidence, and small heads of ordinary varieties of cabbage are measured by the quart and sold for five cents. Inferior quality is most apparent in stale eggplants, and especially in tomatoes, many of which are unfit for food. Tomatoes show the effect of the recent wet and sunless days perhaps more than any other vegetable, and the better grades now in our markets at fifteen cents a pound are of comparatively poor flavor and color, so that some idea can be had of the kind sold on Mulberry Street for two cents a pound, and these are not the poorest seen there. The economy practiced with potatoes, which are generally very small, is more reasonable, and three cents a quart is the prevailing price—less than half that asked for larger ones in better markets. On the other hand, large size counts with peppers, and immense ones sell at the rate of two for three cents. The stock is offered from push trays along the curbs and counters on the sidewalk along the house fronts, while there are occasional shops with medleys of garlic, dried leaves and herbs for flavoring, dried peas, lentils, and beans of many sizes and colors, some large brown ones being parched and encrusted with salt. Olives, black and green, and prunes and capers in oil are exposed in tubs, and an unhusked grain, some form of millet from Italy, is shown in barrel lots, at ten cents a quart. Watermelons, whole and in sections, are almost the only fruit offered here. Many of the staple vegetables come from the wholesale markets, while the salad greens and gourds are grown by the venders and by other Italian farmers in New Jersey.

Very interesting is a little bulletin of a dozen pages issued by the Agricultural Experiment Station at Berkeley, California, and giving an account of the researches of C. W. Woodworth in relation to the vine hopper. The vineyards of that state are injured in the first place by the mysterious Anaheim disease, which has so far baffled all investigation and destroys vineyard after vineyard, with nothing to arrest its progress. Then come phylloxera and the mildew, for both of which there are remedies which at least hold these ravages in check. Lastly is the vine hopper, which is not so serious in itself, but against which all remedies formerly used have proved unavailing. It seems that the life-history of this insect has hitherto not been understood. A great deal of time and money has been spent every year in attempts to destroy the eggs in winter, when, in fact, the insect does not pass the winter as an egg. Much trouble has been taken also to kill the insect in the soil, but it does not pass the winter in the ground. The vines have been sprayed in winter under the supposition that the bark is full of eggs, or that the insect is hiding beneath it, but the insect does not pass the winter on the vine. Neither does it pass the winter in fallen leaves, so that the money spent in destroying these leaves has been wasted. The fact is, that during the winter the perfect insects are feeding on all sorts of green plants, but they only take food enough to meet their present needs, so that their ravages are not noticed. It is in the spring when they begin to grow, and food is needed to produce their eggs, that the young Vine-leaves find them waiting. Spraying the leaves with poison is of no avail, for they suck the juices from the inside of the leaf with their proboscis. They are small insects, it is true, and they take but little. But in the drier parts of the year they stop the growth of the leaves and kill them. There is no occasion here to give any further sketch of the history of the insect nor to quote the various remedies which have been used, together with the reasons why they have been ineffectual. Suffice it to say that in the spring-time jarring, as we treat Plum-trees in the east, is useful. A so-called hopper dozer is a contrivance similar to fly-paper, against which the insects are made to leap and stick fast, and this is also to a certain extent effective. Better still is a palm-leaf fan and a can of the sticking mixture large enough to dip it into. Skillful men working in pairs can do great execution. And finally a common conical bag-net attached to a handle is often found effective early in the morning all summer long. It is useless to try to exterminate this pest. The treatment recommended is based on the fact that a considerable number of hoppers do little injury to the crop. The problem is how to reduce their numbers below the danger-point. Whenever the Vine grower finds that these pests are appearing in dangerous numbers, if he sets his nets going at once he can probably destroy enough to save his crop at a cost of from fifteen to twenty cents an acre. If the Vine grower can develop a judgment which can be trusted as to when the insects are appearing in dangerous numbers, the net and the palm-leaf fan are the most promising means of defense against their ravages.

## The Rejuvenescence of Old Trees.

ON page 314 of this issue is the portrait of a large White Oak, possibly two centuries old, growing in the Arnold Arboretum. The top filled with dead branches and the sparse foliage show that the tree is in a decrepit condition. This was the effect of long neglect, exhausted soil, and the fact that a park road had recently been built almost at the foot of the tree. Some of its roots had been cut in excavating for the road, and the conditions of its surroundings had been changed by lowering the water-table in order to secure drainage for the road-bed. This old tree, the largest Oak in the Arboretum, appeared doomed. An attempt to save it, however, was made by pruning, and the effect of this appears in the illustration on page 315, in which the same tree is represented twelve years later. The dead wood was all cut out, the long branches shortened severely in order to increase the leaf-surface by more vigorous growth and so improve the vitality of the tree, and the ground about it was dug over and top-dressed. The result has certainly been successful, and there is no reason to doubt now that the tree will live many years longer.

This whole subject of the rejuvenescence of old trees was discussed on page 349 of our first volume, published nine years ago, and, as the subject is one of general interest, we reproduce our article with its illustration, with the remark that our experience and observation confirm the value of the system, and that while unnecessary and injudicious pruning certainly does more harm than good, old and decrepit trees can certainly be improved by practicing the De Car's system:

"The fact that old and apparently decrepit deciduous trees

Fig. 1.

Fig. 2.

can be rejuvenated by judicious pruning, is not well understood in this country, where old trees, which might, perhaps, be made to live a century or two, are often allowed to perish unnecessarily. The death of a tree can generally be traced to a gradual failing of vigor due to insufficient nourishment, or to internal decay, the result generally of neglect. The first indication of danger usually appears at the top, and when the upper branches of a tree begin to die, it is a sure indication that, unless radical measures are taken to check the trouble, it can only live a comparatively short time. Vigor can be restored to a tree in this condition by shortening all its branches by one-third or one-half of their entire length. The only care needed in this operation is to cut back each main branch to a healthy lateral branch, which will serve to attract and elaborate, by means of its leaves, a sufficient flow of sap to insure the growth of the branch. This is essential in good pruning, and, if

neglected, the end of the branch will die back to the first lateral branch or bud below the cut, leaving a point of danger to the tree. Care, too, must be taken to shorten the branches in such a way that the lowest will be the longest, that the greatest possible leaf surface may be exposed to the light. Figure 1 will serve to show how an ancient Oak should be pruned for the purpose of increasing its vigor.\* The vigor of a tree depends upon the power of its leaves to elaborate plant-food. The larger the leaf surface exposed to the light, the greater will be the vigor of the tree. The object of pruning, therefore, is to increase leaf surface. If half of a branch of a decrepit tree, bearing small and scattered leaves, is cut away, the leaves which will grow upon the half which is left will be so large that their total area will often be more than double the total area of the leaves upon the whole branch before it was cut. The truth of this statement can be easily verified by cutting down to the ground in the spring a feeble seedling Oak, or, indeed, any young seedling tree, when a tall, vigorous shoot, twice the height and diameter, perhaps, of the slender stem it replaces, will appear at the end of a few months, and, although this shoot will only produce a few leaves, its greater vigor is due to the fact that a larger leaf surface is presented to the light by these few large leaves than by the more numerous smaller leaves of the original plant. The vigor, too, of a tree can be increased after it has been pruned by a good top-dressing of well-rotted manure, or of fresh soil applied over its roots; and trees growing on banks can often be benefited by deepening the soil on the lower side. A large body of plant-food can thus be supplied without burying any part of the trunk and without injury to the tree.

"The internal decay by which so many old trees perish, through inability to resist the influence of storms, is caused by dead branches allowed to remain upon the tree or from the stumps of branches left in pruning. It is an almost invariable custom in this country, when a branch is cut from the stem of a tree, to leave a stump a few inches long, as shown in Figure 2. The end of this branch, as it has no lateral shoot to insure

Fig. 3.

\*We are indebted to the Trustees of the Massachusetts Society for Promoting Agriculture for permission to reproduce these figures, which are extracted from Monsieur A. des Car's work upon Tree Pruning, of which an English edition was published in 1881, by the Massachusetts Society, under the title of "A Treatise on Pruning Forest and Ornamental Trees," a work in which the whole theory of pruning is clearly explained and illustrated.

a flow of sap, is not healed over with a new formation of wood and bark, and soon dies. Decay thus begins, as appears in Figure 3, and this decay gradually extends into the interior of the trunk, as shown in Figure 4, ruining the tree for any useful purpose, and so weakening the supporting power of the stem that a severe gale will prostrate it. This decay can be prevented by cutting off dead branches as fast as they appear, and by cutting living branches, when it is necessary for any reason to remove them, close to the trunk or close to a lateral branch. The secret of good pruning lies in cutting close, so that the wound may heal by the formation of a new growth over the cut surface. No matter how large it may be necessary to make the wound, no branch stump, large or small, should be left in pruning. A coating of coal-tar applied to the wound as soon as made will serve to protect it from moisture, and will not interfere with the formation of a new layer of wood.

"Pruning, so far as the trees are concerned, can be done at any time, except in very early spring, when they are gorged with sap and 'bleed' more freely than at other seasons of the year. The autumn, however, is found to be the best time for such work. There is more leisure now than earlier in the season, while the coating of ice which often, in this climate, covers the branches of trees in winter, makes it difficult and dangerous to work among them.

"Three men at least are needed to prune a large tree properly, and to manage the long, heavy ladders which

this operation makes necessary. One man stands at a little distance from the tree and directs where the cuts shall be made; the second man uses the saw, which must be attached often to a long handle; while the third holds one end of a rope fastened to a belt on the man in the tree, and passed over a branch above his head as a precaution against a fall. Nearly all our forest trees bear severe pruning of this sort, and improve under it. Decrepit Red,

Fig. 4.

Black, White and Swamp Oaks, Black Birches, Beeches, Hickories and Elms have been pruned in this way in the Arnold Arboretum, where many of the trees in the natural woods were perishing from pasturage and neglect. They were covered with dead branches, the foliage upon them was thin and poor, and their dying tops showed that they had but a short time to live. It was important to preserve many of these old trees until a new growth of self-sown seedlings could be brought on to replace them and a covering to the forest-floor grown. A portion of these old trees are pruned each year, and those which were operated upon first, or six or seven years ago, show, in their dense, dark-colored foliage, compact habit and vigorous growth, how pruning can, without fresh soil and without the aid of manure, put new life into feeble and dying trees.

"If often happens that when trees have grown together thickly, as in a forest, they are destitute of lower branches. When such trees are thinned, as often happens in the improvement of grounds, single specimens are left with long, straight stems, and without foliage except at the very top. Such trees, from the point of view of ornamental gardening, are ugly objects, and are, moreover, liable to blow down in the first gale.

"But there is no deciduous tree, however tall and unsightly it may be, which cannot be gradually converted into a handsome, branching specimen, by the aid of a saw and a pot of coal-tar"

MISS ABBIE A. BRADLEY, of Hingham, Massachusetts, has made a gift of \$20,000 to the President and Fellows of Harvard College, in honor of her father, William L. Bradley, the originator of the great fertilizer business which bears his name. Notwithstanding the large commercial enter-

prises in which Mr. Bradley was engaged he had an absorbing interest in trees and in tree-planting, and it is this phase of his life which his daughter has wisely determined to exemplify in the memorial. She has provided, therefore, that the income of the memorial gift is to be expended by the Director of the Arnold Arboretum at that institution for the purpose of increasing by scientific investigation the knowledge of trees. Previous gifts to the Arboretum have been made to erect buildings or for some other immediate expenditure, and this is the first endowment whose proceeds can be counted on in the interest of arboricultural science for all time to come. The form which this memorial has taken is quite as creditable to the public spirit and wisdom of Miss Bradley as the original conception is to her filial affection.

### Planting for the Future.

ONE of the gravest difficulties with which the landscape-gardener has to contend is the lack of imagination in his clients. They have not the prophetic eye to see that when the debris is cleared away and the time comes to pay the bills, the finished work as it then appears is not the realized ideal of their artist, and not what they have paid for, but only the embryo of it. These clients are always well-to-do, and often wealthy. They have been accustomed to order furniture, carriages or what not, to sign a contract for building a house or a yacht, and presently the furniture or yacht is turned over to them unimprovable and complete. There are no new developments to hope for, but there are also none to wait for. There is no suspense, but there is no expectation.

The work of the landscape-gardener is essentially different. It must be waited for, and a great part of its charm to its possessor lies in the hopes he has of it. It depends principally for its means and materials on trees and shrubs and plants, things in their nature changeable, and attractive because they are changeable; things insignificant and uninteresting to the casual beholder in their beginnings, but only in their beginnings available. The designer of a landscape can boast that while the works of all other architects begin to decay from the moment of their completion, his alone begin to improve. But so few besides himself understand this that he has to wait through weary and dreary years for general appreciation and often for the appreciation of his client, whose approval is so important. This approval is important not merely from the commercial point of view, which makes it necessary that he who would sell his goods must please his customers, but from the point of view of the artist himself, who, however conscious he may be of work soundly conceived and conscientiously carried out, cannot but feel ill at ease under the dissatisfaction of his employer, though he is aware that this dissatisfaction is born of inexperience and impatience.

This difficulty, which every one who creates a design out-of doors meets in a greater or less degree, is due, as already stated, to lack of imagination. The imagination needed here is of a peculiar kind, and only the result of much training and experience. It is the faculty of perceiving how a new-created work will appear after the lapse of years, many or few. It is the faculty which enables its possessor to look at a landscape as it now is and take a mental photograph of it when the naked hills are clothed with trees, and the valleys changed from waste or farm lands to lawns or shrubberies. Any one not accustomed to this kind of exercise, who will shut his eyes and try to see clearly such alterations and developments of any scene, natural or artificial, that may meet his eye, will find how difficult is such a mental process. And it is not to be wondered at that the majority of people, even of those who are enterprising enough to face the risks and anxieties of systematic landscape gardening, should be, in spite of themselves, disappointed with the results as they see them in their beginnings. Being without the necessary practice in looking into the future, their vision cannot be prophetic; and

to their eyes, the ill-clothed sticks that are shrubs, though shrubs ungrown, and the unfurnished poles that are trees, though trees ungrown, give no promise of the rich and scene-changing vegetation that will be evolved from these meagre twigs and branches. In a dozen years' time these Snowballs or Mock-Oranges, that now are so mean and insignificant, may fill the view with plentiful foliage and blossom, and hide unseemly objects, natural or artificial; and the new-planted trees that seem merely to deface the lawn, or stand on the hillside to make their loneliness more conspicuous, may change the entire character of the prospect and give it a breadth and dignity. But the eye of the average spectator only sees the scene of the moment, not of five or ten years hence; and after having spent thousands of dollars and endured the trouble and anxiety of seeing his place upheaved by grading, cultivating and planting, the employer of a landscape-gardener may seem to himself to have acquired little for his pains and expense beyond such as there may be of the complete and obvious work of the road-maker and mason.

This is an evil which inheres in the very nature of such work, and the weakness of human nature not to be entirely avoided. It remains for the artist to warn his employer that the work even when pronounced finished will probably seem meagre and unsatisfactory, and to encourage him to console himself by watching its yearly development and increase; he can point out that in the hopes he has of it lies a great part of his pleasure, which he will lose by giving it up to his impatience. It remains for the employer to exercise what patience he may and to enter into the views of his landscape-gardener as best he can, resting assured that as his sympathy with nature increases and his appreciation of her beauties develops he will have a keener delight in watching the growth of his plants than any other pleasure they can give. And even if at last the landscape-gardener suffers from want of immediate appreciation, he can reflect that, like all serious and conscientious workers, artists or not, he is working for the future.

Pittsburg, Pa.

### Weeds in Southern New Jersey.

NOT a season passes but we find some weeds not before observed, and the wonder is how they reach us. This summer I found the Hare's-ear Mustard, *Conringia orientalis*, growing in my garden. This plant is so little known that it is not yet mentioned in any of our text-books, so I was greatly puzzled over it until I saw the circular sent out by the United States Department of Agriculture entitled "Three New Weeds of the Mustard Family," and here was an excellent figure of my weed, and the mystery was solved about its presence in my garden. It must have come from the far north-west in imperfectly cleaned wheat which had been fed to chickens. The gardener had brought earth from the chicken-yard to replenish the flower border, and so this strange westerner had found a home among our familiar flowers. It is not a dangerous-looking plant, but rather attractive, as will be seen from Professor Dewey's description quoted from the circular referred to:

Hare's-ear Mustard is a rather slender branching annual, smooth and grayish throughout. The comparatively large, oval, succulent leaves suggest the popular name. The leaves at the base are broadly spatulate; those of the stem elliptical or oval, clasping at the base, and two to five inches long. The flowers are of a creamy white, about three-eighths of an inch in diameter, and produced in clusters at the extremities of the branches as in the common Mustards. Flowers are produced continuously throughout the season, and are followed by racemes of seed-pods on rather stout, spreading pedicels about half an inch long, which become separated at intervals of half an inch to one inch as the branches elongate. The seed-pods are nearly straight, about four inches long, diamond-shaped, or nearly square in transverse section, and about one-eighth of an inch in diameter. The average number of seeds borne by each pod is about fifty, and an average plant bears from forty to one hundred pods, maturing from the first of July

until the plant is killed by frost. The seeds are reddish brown, oblong, nearly flat on one side and rounded on the other, about a tenth of an inch long by one-sixteenth of an inch wide. They are large and heavy enough to pass with the grains of wheat and oats through the thrashing-machine, and, in fact, they can be completely separated from these grains only by careful manipulation with the best fanning mills or modern cleaning machines. It is practically impossible to separate them completely from flax-seed.

The peculiar foliage of the plant and its clusters of creamy white flowers entitle it to a place in the flower garden, while the crisp, tender leaves with a mild mustard flavor make very good salad. But if planted for these purposes in the garden none of its seed should be allowed to fall.

The pretty little Snapdragon, *Antirrhinum orontium*, I noticed for the first time this summer. It came from Europe many years ago and settled in Virginia around old fields and gardens, from whence it has slowly traveled until it has reached most of the Atlantic states. It is quite a handsome little plant with a pink-purple corolla which looks like the face of some animal.

A smallish composite plant, *Galinsoga parviflora*, is another weed observed for the first time this season. The small heads are about thirty-flowered, and under the microscope the achenes show rough-looking points. It commences to flower when not more than two or three inches high, and continues its growth and flowering until it is a foot or more in height and breadth. It comes from South America, and from reports of the Agricultural Department it is rapidly spreading through the eastern states.

The Bracted Plantain is another and more dreaded weed that has made its appearance here this summer. The Lance-leaved Plantain, or Ribgrass, is the worst enemy we have had to contend against on our lawns, and now if this new relative—the Bracted Plantain—is to be added to our noxious weeds, we shall have to maintain a perpetual warfare. Farmers' Bulletin, No. 28, issued by the Department of Agriculture, says that this weed has appeared in abundance in meadows, pastures and lawns in many localities from Maryland to Illinois during the past season. Although generally reported as new, it has doubtless existed before in small quantity and with less robust habit in many of these places. In some instances, however, it is known to have been introduced during the past season in lawn grass seed. An average plant is said to produce about fifteen flower-spikes, and an average spike bears about a hundred flowers or two hundred seeds, making a total of about 3,000 seeds to the plant.

Among the longest-established and best-known weeds here is the Wild Carrot. There is a law against harboring it, but, like many similar laws, it is never enforced, and so in many places it runs riot. I must confess, however, to a liking for this renegade. Its handsome white flat cymes of lace-like flowers look cool and inviting, and its foliage is handsome, too. But this cannot be said of the Wild Garlic, which is a troublesome weed in our grass lands and on our roadsides. Milk is sometimes so badly tainted with it that it is unfit for use. Like most of our noxious weeds, this, too, is a foreigner and hails from Europe. In Circular No. 9 of the United States Department of Agriculture are figures and descriptions of this vile pest, and the best methods of eradicating it, which everybody should heed. The circular states that it is the most injurious weed at the present time in the middle Atlantic states.

Among our most attractive weeds is *Galium Mollugo*, which was first observed about New York somewhere in the sixties, and is now a roadside weed, and is also found in fields and pastures. It has a deep, strong root which sends out numerous branches ending in long panicles of white fragrant flowers. The root increases in size from year to year, until one plant will cover quite a space. If it is mowed frequently it will adapt itself in a way to keep clear of the machine by sending out long flowering branches which lie flat on the ground. It is a pity that this handsome plant cannot be kept from becoming a way-faring nuisance. Our native *Galiums*, of which we have a

number of species, know their place and never encroach on our cultivated grounds.

The little foreign yellow Bedstraw, *Galium verum*, is here, too; it has numerous bright yellow flowers, and is a more slender, delicate plant than the former and can scarcely become a pest. Another handsome weed growing abundantly on our roadsides and coming into our lawns, is the

### Plant Notes.

*PLATYCODON MARIESII*.—As recently noted in GARDEN AND FOREST, *Platycodon grandiflorum* is one of the best of the old purple garden flowers, being perfectly hardy and reliable in flowering and readily increased by seed or division of root. The white-flowered forms, which are usually

Fig. 40.—A Decrepit White Oak in the Arnold Arboretum.—See page 311.

European Hawkweed, *Hieracium aurantiacum*. It has a cluster of deep bright orange heads of flowers, and when not too abundant is a welcome sight. Its cluster of leaves lie flat on the ground below the reach of the lawn mower, and, following the example of the *Galium*, it is now forming the habit of sending out flowering shoots on the ground to escape the mower.

Vineland, N. J.

Mary Treat.

more or less flecked with purple, are even more attractive. But while in flower these plants are apt to become over-weighted by their large blooms and prostrated unless staked up. On account of this drawback this species is not as satisfactory as *P. Mariesii*, which produces flowers fully as large and as attractive as those of the ordinary type on stems only a foot high. The white form of *P. Mariesii* is a handsome flower, and there are also semidouble forms of the

Fig. 41.—The same Tree Twelve Years Later.—See page 311.

same color. This *Campanula* is not as large or handsome as the *Ostrowskia magnifica*, but it is a decidedly better garden plant, as it will live and flower every season. While *Ostrowskia* may live, if conditions are to its taste,

the chances, on the whole, are rather against its flowering even after making good growth early in the year.

*ANTHOLYZA CROCOSMOIDES*.—This plant is said to be a hybrid between *Antholyza paniculata* and *Crocoshmia*. It

is now in flower, and is, I suppose, a production of Herr Leichtlin; at least, it was distributed from the Baden-Baden garden, where it is said to have proven hardy for several winters. It is an attractive plant, flowering here at a height of about two feet. It has many of the characteristics of the *Antholyza* in its ribbed leaf and many-flowered stems with opposite flowers. These flowers are a bright orange-red, with yellow markings about an inch and a half broad with three inner and three outer segments and a bent tube. While not as richly colored as *C. aurea*, it is an attractive gain if it proves hardy.

**NYMPHÆA LILACINA.**—This hybrid Water-lily of Marliac, for which we are indebted to Mr. Brydon, who imported it a year or two ago, does not seem to have received the attention to which it is entitled, perhaps because it is still rarely seen in cultivation. Cut flowers, especially if a trifle old, as seen at exhibitions, give one a rather poor idea of the beauties of Water-lilies, which are seen at their best only in some quiet pool with a foil of crystal water. Unlike the well-known *Nymphæa Laydekeri*, which it resembles in color, *N. lilacina* may be increased by division. Its leaves are similar to the former variety, but the petals are wider and more numerous, and it has a larger array of golden stamens. It is difficult to convey an idea of the exact differences between the two hybrids without an illustration which would show them clearly. As the flower of *N. lilacina* is also larger and as bright in color and apparently as free-flowering, it seems to me that, on the whole, it is an improvement on the older variety. *N. Laydekeri*, however, is a good reliable variety, even if after five years the old plant is no larger than at first planting and has never shown a sign of increase.

### The Fall Planting of Fruit-trees.

LAST week we gave a brief review of Professor Bailey's *Principles of Fruit-growing*, a book which we recommended to the favorable notice of all persons engaged in growing the orchard fruits especially. As a matter of timely interest we reproduce here some of the reasons why, in Professor Bailey's opinion, the autumn is generally a better time to plant fruit-trees than spring.

My opinion is that fall planting is generally preferable to spring planting upon thoroughly drained soils, particularly for the hardy-tree fruits, like Apples, Pears and Plums; and if the ground is in good condition and the stock well matured, Peaches can sometimes be set in October, even in the northern states, with success. The advantages of fall planting are several. The trees become established during the open weather of fall, and they usually make a start in spring before the ground is hard enough to allow of spring planting. This early start not only means a better growth the first season, but, what is more important, trees which get a very early hold upon the soil endure the droughts of midsummer much better than trees planted in the spring. Planting is nearly always better done in the settled weather and workable soil of fall than in the capricious days and in the hurry of spring-time; and the orchardist is free to begin cultivation at a time when he would otherwise be planting his trees. Again, it is generally better to buy trees in the fall, when the stock of varieties is full and when the best trees are yet unsold; these trees must be kept until planting-time, and it is fully as cheap and about as safe to plant them directly in the field as to heel them in until spring.

In fall planting, however, it is important to insist that trees shall be thoroughly well matured. In order to move stock quickly, it is the practice of some nurserymen to "strip" the trees before the growth is completed; that is, the leaves are stripped off, the growth stopped, and the trees are put upon the market for September deliveries. This process weakens the trees, and many failures in young plantations are probably attributable to this cause. Such trees may die outright, especially if set in the fall and a hard winter follows; or they may live to make a dwindling growth the first few years. Like early weaned calves, they lack vitality and push. If one were setting an orchard in the fall he should place his order for trees

in August or September, if possible, with the express stipulation that the trees should stand in the nursery rows until the leaves begin to die and fall. In the mean time the land should be fitted and the holes dug, so that when the trees arrive they can go directly into their places without delay or without the expense of heeling them in. Trees are mature enough to dig late in September or early in October in the northern states, depending upon the season, soil and variety. When the tree is fully matured, some of the leaves will still hold upon the vigorous shoots, and these are stripped off; but this stripping does no harm, for the young growth is then mature, and it has a thick, strong, brown appearance which is very different from the slender, soft and green branches of early stripped trees.

### Plants in Flower.

VERY beautiful at this season is *Ipomœa rubro-cœrulea*, a Morning Glory which has been in cultivation for several years, and it is of that pure blue tint which almost justifies the California name of "heavenly blue." In that state it will cover a long trellis in a single season, and its flowers are more than three inches across. It is entirely different from the common Morning Glory, but if started in pots here and set out when the weather becomes warm it will bloom freely for two or three months. The seed ought not to be planted earlier than March, for plants resent any check in their growth. It is a Mexican plant.

In the hardy border *Thermopsis Caroliniana* has just passed out of bloom, and it is an excellent plant where bright yellow flowers are wanted. It is tall, and, like other leguminous plants, does better the longer its roots remain undisturbed. For this reason it is better to start it from seed or with a very small plant, for the check the large roots receive will keep it from blooming and the plant may never get to be well established. The flowers are something like those of the Lupin in form, but the foliage of the two plants is not at all alike.

An interesting little plant is *Meconopsis Cambrica*, often called the Welsh Poppy, with orange-colored flowers, two inches across, and borne something like a foot above the ground. It seems quite hardy here, but it can be grown as an annual in places where it will not endure the winter. Where a low-growing plant is needed, this Poppy can be commended. Another plant of low growth, and which when massed in a bed makes a very handsome display at this season, is *Brachycome iberidifolia*, or the Swan River Daisy. The flowers are about an inch across, but they are borne in great profusion, and are blue in color, resembling the *Cineraria* in shape. When several of these plants are grouped together in an open place they produce an admirable effect, especially when in light soil, and they keep blooming for weeks together.

A good plant to associate with our native Lilies at this season is *Pardanthus Sinensis*, often called the Blackberry Lily. Its flowers are borne at the extremity of long stems, and their bright orange color, with dark spots, makes them interesting, although they are not showy. They also harmonize admirably with the pendent white flowers of *Galtonia candicans*, and the combination is a good one to remember when providing for this particular season. *Pardanthus Sinensis* will grow from seed, and it is even said to be naturalized along some woodland walks, for it has the adaptable habit of growing well in shade.

New Haven, Conn.

R. A.

### Some Good Shrubs.

THE Cornelian Cherry is a very old plant and is used to a considerable extent in park planting for its bright yellow flowers, which appear very early in the spring before the leaves; but it is good all the year through and wherever a shrub with clean foliage is needed, and already it is beginning to show its bright-colored fruits. Its botanical name, *Cornus Mas*, shows that it is connected with our native Dogwoods, which are all of them good shrubs or small trees, but, taken altogether, this Cornelian Cherry is the very best of the exotic Cornels for American planting.

Fortunately, it has become something of the fashion lately to plant the Sweet Pepper-bush of our swamps, but it is only within a few years that nurserymen have kept it on sale. It is really one of the best of our native shrubs, and if it is once set in good soil it is almost sure to live. There is a southern species, *Cornus acuminata*, and there is a variety with leaves covered with a snowy tomentum and larger flowers; but the ordinary *Clethra alnifolia* is an admirable shrub with good foliage, and at this late season when shrubs in flower are

scarce the upright racemes of pure white flowers above the glossy leaves are singularly effective. The flowers, too, are very fragrant.

The Button-bush, *Cephalanthus occidentalis*, is an inhabitant of swamps, and is often found with its roots under water. Like many other plants of this class, it does equally as well on dry ground as it does in marshy land, and while it is very beautiful in its native swamps it certainly would grace any cultivated grounds, although it might be used with good effect along the margins of brooks in company with dwarf Willows and Alders. Its flowers are arranged in perfectly spherical heads, poised gracefully at the ends of slender branchlets, and they are so full of nectar that they constantly invite the bees.

New Rochelle, N. Y.

## Correspondence.

### Seasonable Notes.

To the Editor of GARDEN AND FOREST:

Sir,—In the greenhouses of B. P. Cheney, Esq., at Dover, Massachusetts, is a fine specimen of *Asparagus Sprengelii* which measures six feet in diameter. It made a fine display when in bloom recently, covered with thousands of white saucer-shaped flowers. This new plant will prove of great value to decorators, as it can be effectively used in almost any form. It can be trained into pyramidal or loose bush form, or naturally takes a graceful and drooping form. As a basket-plant its lively green is effective for relieving bright colors. It grows quite rapidly, and from a small plant in a five-inch pot this spring it has been successively shifted on as new roots formed, until now it is in a ten-inch pot. It delights in a well-enriched soil, rather light in composition, with plenty of drainage. New crowns form quickly, and, as it divides quite freely, there will soon be an abundance of it. *Adiantum Farleyense* has always succeeded well here. It is generally given a shady position in the tropical-plant house, but this is not really essential. It delights in shade, but must be near the glass. A little fire-heat is required in cool or damp weather to prevent mildew and discoloration of the fronds. There is enough here to fill one side of a large greenhouse, and it makes a beautiful bank of green. Besides good turfy loam, with a little cow manure, there are no special requirements in its cultivation.

A Japanese gentleman sent to an acquaintance in Framingham, Massachusetts, a packet of seed of the Japanese Morning Glory, and some of the plants are now in bloom on the estate of David Nevins, Esq., of that town, where they prove a great attraction. In form and color shadings the flowers resemble *Gloxinias*, and detached flowers might easily be mistaken for them.

The fine specimen of *Larix Kämpferi*, the Japanese Larch, on the grounds of H. H. Hunnewell, Esq., at Wellesley, is now carrying a heavy crop of seed-bearing cones. They are borne on the upper side of the branches. The bracts are broad, short and heavy in texture, with a comparatively open arrangement. This tree has been bearing seeds for ten years, and seedlings have been raised here and at the Bussey Institute. Seeds are planted in autumn, wintered over in a cold frame and come up in spring. Another remarkable specimen of this Larch is to be found on the estate of Mr. Probasco, a gentleman who has done much for horticulture in Cincinnati, Ohio. Mr. Probasco, when here last summer, stated that his specimen is a little the larger.

At Mrs. Cheney's place I noted a first-rate plan for Celery culture. The Celery is planted between bushed Peas of moderate height, which, during warm, dry summer weather, provide good shade. We have given up the laborious practice of digging trenches for Celery, and consider it a waste of time. To dig in a uniformly good coating of manure and draw out shallow trenches with a hoe is all the preparation we make. Except for the convenience which trenches afford for watering, we would plant on a level. Planting as we do, we can grow a crop of Lettuce, Peas, Beans or Beets between the rows, and get the crop off before it is time to earth up. With the exception of White Plume and Paris Golden, little earthing is done. The bleaching is done after the Celery is packed away, with sand between the rows, in deep pits for the winter. The claim that White Plume and Paris Golden need no bleaching is not quite just. They do require to be bleached, or they are stringy and bitter; they can, however, be prepared in half the time that ordinary kinds require. The Admiral Pea has again proved our best sort, and is the heaviest cropper I know. The flavor is equal to the well-known Champion of England. The pods are filled their entire length, and as the grains are small they maintain a good

table appearance for a long time. The Marshall and Brandywine Strawberries have done finely with us this season. It is interesting to compare notes, and it is seldom gardeners agree in their preferences; one wants the Leader, another Bubach No. 6, a third favors Eureka or Belmont, Gandy or Burnette, while yet another considers Parker's Earle without a peer. Soil and location seem to have much to do with success. Even so late in the season a good word should be said for the Emperor Forcing Lettuce. The heads are small and can be set six inches apart. Planted at the same time as Hettinger's Belmont, it is five days ahead of that variety, and in spring-time Lettuce is estimated by the heads rather than size. A row of Scarlet Runner Beans combines the ornamental with the useful, and a few of the fine scarlet pea-like flowers mixed with a bunch of Sweet Peas make a striking combination. The pods are excellent cooked as Snap Beans.

Wellesley, Mass.

T. D. Hatfield.

## Periodical Literature.

The last addition to the useful *Hand-lists* of the Kew collections of living plants is devoted to tender Monocotyledons, excluding Orchideæ, which has just reached us, and forms a volume of 347 pages. In it are included lists of the Seitamineæ, Bromeliaceæ, Cape bulbs, Aloes, Yuccas, Agaves, Palms, Screw Pines, Aroids and Grasses grown under glass in the Royal Gardens. Of the Scitamineæ, including the Gingers, Arrowroot-plants and Musas, of which 450 species are known, 240 are in cultivation at Kew; almost all are natives of the tropics. In 1813 forty species were enumerated in the second edition of Aiton's *Hortus Kewensis*, and 139 before 1864, as shown in John Smith's privately printed *Records of Kew*. It may be mentioned that *Musa Ensete*, one of the best-known representatives of this family, the noble Abyssinian Banana, was introduced into cultivation at Kew from seeds sent by the British Consul at Massowah. *Strelitzia Reginae*, another well-known plant of this family, was introduced by Banks into the Royal Gardens in 1773 from the Cape of Good Hope, and another member of this genus, *Strelitzia Augusta*, was first cultivated in the gardens in 1791, when Francis Masson sent it from the Cape.

Of the Bromeliaceæ no less than 252 species are cultivated at Kew, although in 1813 only sixteen appeared in Aiton's *Hortus Kewensis*.

In Cape bulbs the Kew collection has been rich for more than a century, and now numbers twenty-eight species of Hoemodoraceæ, 221 of Irideæ, 488 of Amaryllideæ, and 512 of Liliaceæ, or a total of 1,249.

No less is the collection of so-called succulent plants—Aloes, Yuccas and Agaves—and the house devoted to the cultivation of these plants is one of the most interesting and effective in the Royal Gardens. Three hundred and seventy-seven species of these plants are enumerated in this *Hand-list*.

The history of the Palms at Kew is interesting. Eleven hundred species, nearly all natives of the tropics, have been described, and there are probably many more still remaining unknown. In 1768 six species were cultivated at Kew. In 1787 the number had risen to ten, and in 1813 to twenty. At the present time 407 species, or more than a third of all that are known to science, can be seen in a living state in the Royal Gardens. This is probably the largest assemblage of species of Palms to be found in any one place, although, of course, much larger individuals are to be seen at Buitenzorg and in other tropical gardens.

During the latter years of George the Third and in George the Fourth's reign a new Palm-house at Kew was contemplated and a piece of ground was set apart for its erection, although nothing was done about it until William the Fourth, who took much interest in improving the Royal Gardens, came to the throne. Nothing, however, was accomplished in the way of providing a proper shelter for the Kew Palms until the Royal Gardens became a public institution. The present Palm-house, the finest in the world, was completed in 1848 from the designs of Decimus Burton. The length of this structure is 362 feet; its width in the

centre 100 feet, and its height is 66 feet. The oldest Palm in the house is *Sabal Blackburniana*, from Bermuda. Originally there were two specimens of this tree in the collection, but one was taken down in 1876 for want of room. Smith, in his *Kew Records*, gives the following account of them: "On my entering Kew in the spring of 1820 the first hot house I came to was the Palm-house; on looking in I was struck with what I then considered a wonderful plant, a large-leaved Fan Palm; and I found there was another of the same kind and size at the other end of the house. There is no record of their introduction in the Garden books. Probably they formed a part of the great collection of plants introduced by Admiral Bligh in 1793, on his return home after having introduced the Bread Fruit tree into the West Indies." The large plant of *Jubœa spectabilis*, in the temperate house, is supposed to be one of several plants raised from seeds collected in Chili by Thomas Bridges and purchased from his agent in 1843.

Of the Pandanaceæ, or Screw Pine family, about 115 species are known, half of them being cultivated at Kew, mostly in the Palm-house.

Of the 900 species of Aroids known to science 368 are cultivated at Kew, the number having increased from forty-four in 1813.

Among the Grasses two of the largest species of Bamboos are noteworthy features in the centre of the Palm-house, *Bambusa vulgaris* and *Dendrocalamus giganteus*, the former having been in cultivation at Kew since the beginning of the century.

These Hand-lists are of immense assistance to cultivators. In addition to the present issue, volumes devoted to Hardy Trees and Shrubs and to Conifers have appeared, and it is to be hoped that others, enumerating the other groups of plants cultivated in this, the richest and best-managed of all gardens, will speedily appear.

### Notes.

During last week 1,800 boxes of Mediterranean oranges and 36,500 boxes of lemons reached this port, and 10,700 boxes of oranges and 186,400 boxes of lemons are en route. Cool weather affects the sales of these imports quite as much as some of our domestic fruits, and prices have been unexpectedly low in the absence of a hot wave.

A correspondent of *The Gardeners' Chronicle*, in explaining his method of hybridizing Campanulas, mentions one point of practice that we do not remember to have seen before. In taking up the pollen from a matured anther he uses a bit of black sealing-wax drawn out to a blunt point, and when he wishes to pick up the pollen he rubs the wax on his sleeve until it becomes sufficiently electrified, and then lifts with it the loose pollen and applies it where it is desired almost without touching the flower.

How to propagate the Apple is one of those old questions which pomologists are constantly studying, and in a late illustrated bulletin of the Kansas Agricultural College, entitled "Grafting the Apple," the conclusions are reached that Apple-trees grafted on whole roots are no better than when grafted on piece roots from three to five inches in length; that there is no advantage in grafting above the crown, and that the greatest uniformity in growth is secured by using grafts that will quickly root above the union with the stalk.

Mr. F. C. Stewart, at the branch of the New York Experiment Station in Jamaica, Long Island, is studying a new bacterial disease of Sweet Corn. The plants wilt and dry up, although the leaves do not roll as they do when they die from lack of moisture. In young plants death occurs in a few days, but the disease requires from two to four weeks to run its course in older plants. Externally affected plants appear sound, but when split the fibro-vascular bundles are found gorged with a yellow substance. When a diseased stalk is cut crosswise there exudes from the ends in yellow viscid drops a substance composed of immense numbers of short bacilli. The disease may attack the plants at any stage of growth, but is the most virulent about the time when the ears are forming. It does not spread from an initial centre, but is found scattered

through the field. Diseased plants frequently occur in the same hill with healthy ones. It is found in all kinds of soil, all kinds of weather, and seems to prefer the early dwarf varieties of Sweet Corn. Mr. Stewart asks that this note be published so that he can get information concerning the geographical distribution of the disease, which seems to be common to all parts of Long Island, where in some cases it is very destructive. It has not been reported from any other section, and any one who has noticed it elsewhere will render a service to science by reporting the fact to Mr. Stewart.

The season for Bartlett pears from California is drawing to a close, and prices for this favorite fruit, which has been of unusually good quality this year, advanced twenty-five cents a box last Friday. The seventy-six car-loads of California fruits sold here last week included, besides Bartlett pears, grapes, plums and peaches, and, among many varieties, the handsome Japanese plum, Eureka, commanded the remarkably high rate of \$5.90 a crate at the wholesale auction sales. Diamond, Abundance, Purple Duane, Yellow Egg, Silver, Gros, Tragedy, Columbia, Washington, Bradshaw, Hungarian, Kelsey, German, Quackenbos and other well-known kinds ranged from eighty cents to \$2.50 a crate. Susquehanna, Late Crawford, Decker and Foster are the favorites among peaches, and Flame Tokay among grapes, with Sweetwater and Sultana as the other principal kinds in season.

Most of the late summer varieties of apples are now in market, and showy Red Astrachans and others of bright color, when hand-picked selected fruit, find ready sale at good prices. Duchess of Oldenburg is a favorite, with Gravenstein and Nyack Pippins, all of which sell at retail for from \$3.00 to \$3.35 for the best grade, while windfalls can be bought as low as \$1.00 a barrel. Peaches are still coming from Georgia and other southern states, and from Maryland, Delaware and New Jersey, and include occasional lots of large and well-colored fruit of the desirable later varieties; but most of the peaches from the eastern states are unattractive, and some are so inferior as to meet almost no demand. Bartlett pears are also comparatively poor in the eastern states, those from New Jersey bringing the highest prices. Grapes from North Carolina, while not of choice quality, have been quite plentiful, and five-pound baskets of Delawares and Niagaras sell on the street-stands for twenty cents. Damson, Wild Goose and Botan are among the eastern plums now seen. Currants continue plentiful and cheap, and there are small shipments of red raspberries from the Hudson River district, and of blackberries from that section and from New Jersey, with more abundant supplies of huckleberries from the Shawangunk mountains and from other sections of New Jersey, Maryland and Pennsylvania. Evaporated raspberries, blackberries, huckleberries, cherries, apricots and peaches of this year's crop are offered in the wholesale markets now, while the fresh fruits are yet in season.

Although it has long been known that the sweet potato contains starch in considerable quantities, the question whether it can be made a profitable source for the manufacture of starch on a commercial scale has only recently been raised. Very interesting, therefore, is a bulletin from the South Carolina Agricultural Experiment Station at Clemson College, from which it appears that at least twenty-two per cent. of starch can be counted upon in most varieties of the Sweet Potato, while in some kinds the product ranges still higher. Counting the yield of Sweet Potatoes at from 200 to 300 bushels to the acre in South Carolina, which is moderate, since 500 bushels to the acre have occasionally been accomplished, it appears that the amount of starch yielded by an acre of Sweet Potatoes is much greater than the amount yielded by Corn or Wheat, counting Corn at thirty-five bushels to the acre and Wheat at twenty bushels to the acre. That is, an acre of Sweet Potatoes will yield four times as much starch as an acre of Wheat and twice as much as an acre of Corn. The Sweet Potato even has the advantage over the Irish Potato in this regard in the southern states. Of course, this does not establish the fact that the Sweet Potato can be profitably raised as a starch producer. In the first place, a more thorough test of the quality of the starch and its fitness for sizing will have to be determined. Again, the value of the by-products is much smaller than the value of the by-products in the manufacture of starch from corn. Besides this, much must be learned about the cost of producing the sweet potato, the changes which may take place in storing it and the cost of manufacturing the starch. Nevertheless, the bulletin is an extremely interesting one, and it is full of suggestion as to the proper soils, fertilizers, etc., which the crop demands for its best development.

## The Wild Flowers of Early August.

THE early part of August is, perhaps, the least favorable time in all the verdurous months for those who like to decorate their rooms with wild flowers. Yet its resources are not to be despised, while an intelligent use of them will produce more beautiful results than the average careless gatherer can imagine. Of course, these resources vary according to climate and elevation—the seashore, the low riverland, and the mountain each furnishing its own peculiar supply. Let us see what flowers are furnished by the beautiful hill regions to the westward of New York, and how they may best be employed.

Here and there a head of Golden-rod or a slim spray of Aster may antedate the plenteous harvests to follow, but they should be picked unwillingly, for a wise decorator knows that these plants must be her chief dependence during many future weeks, and that even the most appreciative eye grows tired of too long a sequence of the same colors and forms. Variety is Nature's great resource for keeping us ever content, ever freshly delighted with her outdoor effects—variety in her stretches and touches of bright color as contrasted with the permanent green background which never fatigues the sense. And Nature's example will be imitated within doors by those among her children who really love her, for they understand that she is the best of all artistic teachers.

Thus we are brought to a fundamental fact as regards indoor decoration. Green should be chiefly relied upon when adornments on a large scale are attempted. Branches, shoots and sprays of foliage, different tints of green being selected so that absolute monotony is avoided, should be used for the corners of the hall, the landings of the staircase and that dark hollow of the unused fireplace which throws a large low jar and its verdant burden into such fine relief. Used quite by themselves, if they are large of leaf and stately in design, or relieved by one or two bold touches of color, these great bouquets of foliage are quieter and more restful in effect, usually more harmonious with the furnishings of the room, and more refreshing to the eye than any bright bunches of strong colors. This is true even at seasons which offer us floral color in the most

varied and delicate tones and most beautiful shapes. But in the first part of August, when really lovely flowers are less plentiful, a still greater reliance should be placed upon them, while small and delicate arrangements of simple green—as of little Pine and Hemlock shoots, Ferns and Grasses—are not outrivalled by any blossoms even for the adornment of the dinner-table.

Set upright against plain stretches of wall the level sprays of the Beech exceed all others in beauty, but bolder bits of Hemlock, glistening Tupelo-shoots, Hazel-boughs loaded with their green nuts, and sprays of Maple may be well employed, and, indeed, any sprays or shoots which bear their leaves, not in close clusters, but more or less individually displayed. If an enlivening touch of color is wanted early August gives it in those reddened tips of Maple, Dogwood, or Tupelo, which, while they predict the autumn, do not really show its most vivid tints or its dry and fragile textures.

At this time the most beautiful flowers of midsummer have departed. The red and yellow Lilies, the Spiræas and the Meadow Rue have followed the Laurel into their annual graves, and the late-blooming, white-flowered shrubs stand clothed in plain green again, even the Nine-bark and the New Jersey Tea. But at least one white-flowered shrub is just coming into bloom—the Clethra. It is not as graceful as most of its forerunners, and therefore is less easy to arrange within doors. Yet, if it is not massed too closely, and is intermixed with much green spray, beautiful large bouquets can be made with it, while its spicy perfume will embalm the house.

Very different is the Sumach, now showing at its best its solid flower-cones, of a lovely pale green, or the richest red. This also should not be massed, as one most often sees it, in huge formless bunches. It should be carefully displayed so that its fine fronds of foliage define themselves to the eye, while each fruit-cluster is brought out distinctly against the background they form. With no other boldly decorative plant is a warning against overabundant use more needful.

It is the same with the Thistles. Their beauty is not alone in their handsome heads. It is also in their architectural foliage and their dignity of port. Two or three standing in a very tall, narrow vase appear to much better advantage than a larger array, or than one or two combined with other plants. Neither of the yellow Gerardias—the branched form or the stiff "strict" form—can be made to look quite as well in the house as it does rising from the Fern-carpeted ground of the forest edge. Yet, separated from all other flowers, not too closely crowded, and relieved by an intermixture of green spray, either sort may produce a fine effect. The Pearly Everlasting, with its light gray-green foliage, loses its charm if it is associated with plants of a stronger color, and is apt to injure theirs. But if a bouquet formed of this plant alone is placed in a vase which does not "kill" its delicate hues, preferably in one of clear white glass, it is very individual and lovely. It is like a bouquet grown and gathered and seen by moonlight, knowing nothing of the heat and vigor of the sun.

Among the Desmodiums of the hour there is one of exceptionally delicate beauty. This is *D. acuminatum*, with large three-foliate leaves, and rising far above them, a long and very slender stalk bearing a loose panicle of little pea-shaped blossoms of the loveliest rosy hue. Growing on the border of the woods, a cluster of these Desmodiums looks like a swarm of tiny bright pink butterflies poised at some distance from the leafy level below them. It is impossible to imitate this effect within doors, for a wide green background is needed, as well as a green mat below. The best way to employ these flowers is to discard all foliage and group a number of the flower-stalks together in a narrow-mouthed slender jar. Then they produce quite a different effect, but a delightful one, recalling certain stiff yet delicate floral traceries characteristic of Japanese art.

With the small-blossomed Sunflowers, which are now

abundant, the case is reversed. They are ragged and ungraceful in habit, and therefore look best when used to supply sparks of yellow to large bouquets of foliage. But the Spikenard, again, is attractive because of the way it bears itself, and the combination of its handsome leaves with its large panicles of minute greenish flowers. Two or three branches of this should be set by themselves and given room to spread widely as they do in growth.

Very different, again, are the arrangements which may be made in low basin-like vessels with green twining or climbing plants—Virginia Creeper and Bittersweet, for example—enlivened by slenderer lengths of the Virgin's Bower. This now bears its crop of starry white blossoms, predicting the thick clusters of long-fringed fruit which will mingle so effectively with the red and yellow foliage of a later month.

But the most abundant flowers of the early part of August are those which even their admirers consent to call weeds, and which often grow in an undeniably weedy fashion. We do not refer to the Jewel-weed, which is now in season. It is by no means weedy in habit, but it is useless to the decorator, as it quickly droops when picked. We mean the Milkweeds, the Thoroughworts, the Evening Primroses, the tall Fireweed (*Epilobium*), the ubiquitous Carrot and the other white-flowered Umbelliferæ which plentifully keep it company.

Most beautiful of these, as regards its flowers, is the despised Carrot. Weedy, indeed, is its habit, and very weedy the aspect it bestows upon the fields and roadsides which it overruns. But, closely examined, no flower in the world is more exquisite, and indoors it should be used so that its delicate countenance, not its thin, sprawling habit, is emphasized. It may be mingled, not too profusely, in a large bowl with Ferns and sprays of White Pine, so that its heads scarcely surpass the ends of their leaves. Thus displayed it is a fitting decoration for the dining-table of a princess; and also when its heads are plucked from their stems and floated close together in a flat dish—a mat of fairy lace surrounded by a border of Ferns or of Elder-leaves. The Milkweeds are hard to manage, for they are both coarse in leaf and “floppy” in port. Perhaps they look best when only a short piece of the stem is preserved and they are placed in a low flat dish, so that their soft pleasant colors and the beautiful structure of their small flowers may be observed.

As for the Thoroughworts, white and purple, they are not attractive when closely examined, but in color and in carriage they are charming. Tall arrangements of them, white and purple grouped together, may well be set in the darker corners of the house; and, for once, great quantity will not injure the quality of the effect, provided they are massed, not with their heads all on a level, but with some rising well above the others, so that their graceful dignity shall not be concealed. The yellow of Golden-rod harmonizes well with the dull purple of the Joe Pye Weed. So a few sprays of the autumnal flower may be indulged in, for, added to an arrangement of white and purple Thoroughworts, it will make a bouquet of bright yet soft color suitable to any spot, not too fully illumined, in almost any room. If the hand at work is skillful, a few Carrots or other umbelliferous plants may be added, and, perhaps, one or two small Sunflowers. Simple arrangements are safer as a rule, and this means, of course, combinations of only one or two kinds of flowers. But complex arrangements need not be altogether shunned; and it is good practice in interior decoration to gather a pile of varied Thoroughworts, of white Umbelliferæ, of Golden-rods, Asters and slim Sunflowers, and see how a couple of great vases may be filled with them, so that the general effect shall be harmonious in color and outline, while the special character of each head or spray shall be effectively brought out.

Four years ago (see vol. vi., page 301) we gave an account of the Algonquin National Park of Ontario,

and spoke with some enthusiasm of the foresight of the people of the Dominion in setting apart for public use an area of 1,300 square miles of land and 166 square miles of water. The site itself is from 1,300 to 1,400 feet above the sea-level, and there is no place in the province where so many important streams take their rise. It is a place of singular beauty, comprising a great variety of woodland and water scenery, with primeval forests, elevated lakes and streams which flow under overarching trees. Noble game, fur-bearing animals and many kinds of birds make their home here, so that as a game preserve, as a forest reservation where experiments in systematic forestry can be carried on, as a remnant of the original sylvan scenery of the country which is rapidly being desolated, as a health resort with its pure air and resinous odors, this park was a worthy conception of wise and public-spirited people, and seemed to mark an important advance in the development of Ontario.

Some letters lately published in *Forest and Stream*, of this city, make us apprehensive that the reservation is not actually administered on the lines of its original conception. It seems that much of the Pine timber is being cut, and the landscape is mutilated and defaced in a hundred ways. A delightful little lake is described which was a bit of natural loveliness, wooded to the brink with old Pines. Around it were little bays where Water Lilies grew and where deer came to eat the buds. Now the Pine is cut away, the beautiful island in the lake hardly shows a bit of verdure, a big sawmill is going up at the mouth of the river, with dams, lumber depots here and there, steamboats on the lakes, and projected railroads, so that as a breeding-ground for game much of the park is already useless. This certainly seems like desecration, and when it is added to this that many of the streams have been dammed up so as to kill the timber on their banks by drowning out the tree roots and leaving the lakes surrounded by a fringe of death, we may agree with the correspondent that Algonquin Park will soon be like “a beautiful face seared with a red-hot iron.” Of course, we have no means of verifying the facts of the case, but we sincerely trust that the men of the Dominion will remember that the making of a few hundred dollars now is a small matter when so much beauty and so much genuine utility is destroyed for all time to come.

#### *Rosa setigera.*

WE have frequently called attention to the beauty and value of the Prairie Rose as a garden plant. It has been known for a century, although gardeners are only just learning its value, and, curiously enough, no good figure of it has been published until this week, when we print on page 323 the reproduction of a drawing of flowering and fruiting branches made by Mr. Faxon in the *Arnold Arboretum*.

*Rosa setigera* has been described so often that it is unnecessary to do more than to refer again to its many good qualities, its hardiness and rapid growth, its freedom from the attacks of the insects which disfigure so many Roses, and the charm of its lovely pink flowers which open about the middle of July, when the flowering time of most Roses is passed.

*Rosa setigera* may be trained to a pillar after the fashion usually adopted for the cultivation of its better-known offsprings, the Baltimore Belle and Queen of the Prairie, but to our taste it looks the best when allowed to grow naturally, and to send out without restriction its long arching shoots, which sometimes attain the length of twelve or fifteen feet during the season, and in their second year produce many short erect lateral branches, which bear the crowded flower-clusters toward their extremities. Planted in rich soil, with a dozen feet separating it from its nearest neighbor, the Prairie Rose will grace any garden, and if several hundred plants could be used together in one great mass to cover some broad slope or steep bank in a large park, an effect of surprising beauty would be obtained;

and if in such a mass the plants were set from twelve to twenty feet apart with the ground between them carpeted with the long prostrate stems of *Rosa Wichuraiana*, which produces its fragrant white flowers when the *Prairie Rose* is blooming, a harmonious composition might be obtained.

Single plants of such flowering shrubs as *Rosa setigera* dotted here and there through mixed shrubberies, although in themselves beautiful, often make a plantation spotty and fail to produce the effects which might be obtained by masses of a single shrub or of two or three shrubs harmonious in form and color. The promiscuous mixing up of shrubs and trees of many countries ill-sorted in form and in the color of foliage and flower, is a common fault in most American park-planting, the result in part of a superabundance of material and in part of a want of self-restraint on the part of the planter which manifests itself in a desire to make as much show as possible without much regard for the harmony of the result. An experiment which we have suggested before of massing shrubs of the same kind together in the different parts of a large park or park system, instead of planting everywhere first a *Rose*, then a white-flowered *Spiræa*, then a *Forsythia*, and so on, is certainly worth a trial. Tending to secure breadth, simplicity and unity, it would at least do away with the eternal monotony of American park-planting and produce at different seasons color-effects which only the Japanese have known how to make truly effective.

#### Notes on the Cultivated Brassicas.

IN common with nearly all cultivated plants, especially those which are perplexing, the Brassicas have received too little attention from botanists. The inevitable outcome of such neglect or of any superficial study is a reduction of species, and in this direction Brassica has suffered greatly. It is usually confusing to reduce types. The most perplexing species in our manuals are those which contain the greatest number of old types or synonymous names. It is true that this is supposed to be primarily due to the variation of the species or groups, but I am convinced that it is often to be charged to superficial study or insufficient material. The conviction is growing upon me that our manuals contain too few rather than too many species; at all events, the miscellaneous dumping of *Ruta-bagas*, Turnips, Rape and other plants into *Brassica campestris* is unnatural, and therefore unfortunate. The best presentation of the species of true Brassicas which has yet been made is that of De Candolle's *Prodromus* so long ago as 1824, and my own studies lead me to adopt essentially those conclusions. I am not clear as to the generic merits of *Brassica* and *Sinapis*. If we are to erect generic characters upon general habit, the two might be kept apart, but I have not found structural characters with which to separate them, and for the purposes of this discussion I have kept them together. I should add that I am acquainted with no group in which many of the difficulties of classification vanish more quickly upon a study of the growing plants than in these Brassicas. From my standpoint the group may be divided as follows:

A. Whole plant glaucous-blue when in flower; leaves of the flower-stems clasping; flowers various.

I. Leaves from the first more or less fleshy throughout and glaucous-blue, even when young; flowers large and creamy yellow, the petals conspicuously long-clawed and the sepals usually erect.

1. *Brassica oleracea*, Linn., the Cabbage and Cauliflower tribe. Leaves smooth from the first, and the root never tuberous.

2. *B. Napus*, Linn., the Rape. Leaves smooth from the first; differing from *B. oleracea* chiefly in habit and more deeply scalloped leaves. The botanical position of the Rapes is open to doubt.

3. *B. campestris*, Linn., the *Ruta-baga*. First leaves hairy, the root usually tuberous.

II. Leaves (except upon the flower-stem) thin and green; flowers smaller and bright yellow, less prominently clawed.

a. Plant potentially biennial (that is, the root hard and thickened, often distinctly tuberous); foliage firm in texture.

\* Leaves distinctly hairy.

4. *B. Rapa*, Linn., the common Turnip. Leaves promi-

nently lyrate or interrupted below, the root tuberous.

\*\* Leaves not hairy.

5. *B. Chinensis*, Linn., the Pak-Choi Cabbage. Radical leaves wavy and ample, glossy green, obovate or round, obovate in general outline, either entire or obscurely wavy or even crenate, tapering to a distinct and thick strong petiole, which is generally not prominently margined; pod large and tapering into a beak half an inch long; root sometimes tuberous.

6. *B. napiformis*, Bailey (*Bull.* 67, *Cornell*, 1894), the tuberous-rooted Chinese Mustard. Radical leaves comparatively few, the blade thin and oval in outline, and on long and slender slightly feathered petioles, sharply and irregularly toothed with a thin bloom; beak of the pod more abrupt; root distinctly hard and tuberous.

aa. Plant truly annual; foliage profuse, loose and soft.

7. *B. Pe-Tsai*, Bailey, l. c., the Pe-Tsai Cabbage. Numerous radical leaves, large and light green, oblong or ovate-oblong, crinkled and very veiny, and the margins wavy, contracted into a flat and ribbed petiole one to three inches wide, which is provided with a wide thin notched or wavy wing; stem leaves sessile and clasping; pod of medium size, with a short cone-like beak; the leaves tend to form an oblong, loose head, like *Cos lettuce*.

8. *B. Japonica*, Sieb., the California Pepper Grass, Pot-herb Mustard. Rather numerous radical leaves, oblong or oblong-obovate, the margins either crisped or cut into many very fine divisions, the petiole distinct at its lower end; stem leaves all petioled; pod very small, with a slender beak; the soft, thin leaves make excellent "greens."

*B.* Plant green or but slightly glaucous when in flower; leaves on the flower-stems not prominently clasping; flowers small and yellow. (Essentially *Sinapis*.)

9. *B. juncea*, Cosson, the Chinese Mustard.

10. *B. nigra*, Koch, common mustard of commerce.

11. *B. alba*, Boissier, white mustard.

The most important innovations in this classification are the recognition of the peculiarities of the stem-leaves and the sizes and colors of the flowers; and it is to be noticed that the *Ruta-baga* and Turnip, which are ordinarily thrown together, fall into different categories. The differences between the cabbage-like species and turnip-like species in size and color of flowers is really striking when the plants are flowered side by side. The Turnip-flower is more like that of Mustard than like that of the Cabbage tribes. The breaking up of the Oriental Cabbage tribe into the three species (*B. Chinensis* proper, *B. napiformis* and *B. Pe-Tsai*) is also an innovation, but I am unable to understand the plants in any other arrangement.

The point which I wish to urge particularly at this time is the specific distinctness of the *Ruta-baga* and Turnip, and I will contrast them more minutely. The tubers of the two are different in season, texture and flavor. In the *Ruta-baga* the small leaves immediately following the seed-leaves are sparsely hairy, but all subsequent leaves are entirely smooth, densely glaucous-blue, thick and cabbage-like, with a fleshy petiole and midrib. In the Turnip the radical leaves are always more or less hairy, and they are green and radish-like, thin, with slender petiole, and the leaves are much more lyrate, with interrupted leaflets on the petiole; the small leaves following the seed-leaves are also thinner and narrower and more deeply scalloped. In the *Ruta-baga* the flowers are large, creamy and cabbage-like, while in the Turnip they are small, yellow and mustard-like, with shorter claws and more spreading calyx. The Turnips vary in hairiness, but the cone of expanding leaves, or the "heart-leaves," always shows the hairs distinctly, while the heart-leaves of the *Ruta-bagas* are entirely smooth, fleshy, and remind one of the young shoots of Sea-kale. I have grown most of the trade varieties of *Ruta-bagas* and Turnips, and they may be referred to their respective species as follows. Specimens are in the Cornell herbarium.

*RTA-BAGAS* (*Brassica campestris*).—1, Bronze-top Swede; 2, Burpee's Breadstone; 3, Carter's *Ruta-baga*; Carter's Imperial Hardy Swede; 5, Colson's West Norfolk; 6, Early White Vienna; 7, Improved American Purple-top *Ruta-baga*; 8, Improved Champion; 9, Improved Yellow Summer Turnip; 10, Improved Yellow Swedish; 11, Laing's Improved; 12, Lincolnshire Improved; 13, Long Island Improved Purple; 14, Long White French Turnip; 15, Shamrock; 16, Skirving's; 17, Sutton's Champion; 18, Taunton; 19, White *Ruta-baga*; 20, White Swede or Russian; 21, Yellow French.

*TURNIPS* (*Brassica Rapa*).—1, Aberdeen; 2, Black Stone; 3, Cow-horn; 4, Early Dutch Turnip; 5, Early Snowball; 6, Extra Early Milan Red-top Strap-leaf; 7, Extra Early Purple-top

Munich; 8, German Teltow; 9, Green Barrel; 10, Green Globe; 11, Grey Stone; 12, Long White Tankard; 13, Montmagny; 14, New Golden Finland; 15, Pomeranian White Globe; 16, Purple-top Strap-leaf; 17, Purple-top White Globe; 18, Red-top Globe-shaped; 19, Red-top Strap-leaf; 20, Robson's Golden Ball; 21, Seven-top; 22, Teltow, or Small Berlin; 23, True Jersey Navet; 24, White Egg; 25, White Flat, or Globe; 26, White Model; 27, White Norfolk; 28, White Strap-leaf; 29, Yellow Aberdeen; 30, Yellow Globe; 31, Yellow Malta; 32, Yellow Stone.

*Brassica oleracea* must be held to include, I think, all the Cabbages, Kales or Borecoles, Collards, Brussels Sprouts, and Cauliflower and Broccoli; and most botanists appear to agree that the Kohl-rabi belongs here, but upon this point I am not fully satisfied. So far as I know, *B. oleracea* is the most variable species in cultivation in temperate climates, although Naudin would give this distinction to *Cucurbita Pepo*. But the *Brassica* varies immensely in nearly all its parts, while the important variations of the *Cucurbitæ* are confined to the fruit and length of vine. There are few plants in which contemporary evolution can be so well studied as in this *Brassica*.

The Chinese Cabbages, which are now coming into cultivation, possess unusual interest to both the horticulturist and botanist. They are not only exceedingly variable, but the variations are of such a character as to show very clearly what has been the genetic history of the garden forms. The species is now represented in cultivation by several widely different forms. Hemsley refers the Chinese Cabbages to *Brassica campestris*, but they really have little in common with that much-abused species.

The confusion into which our Brassicas have fallen is in some measure due to the different vernacular names which they bear in different countries. The French use the word *chou* generically to include all forms of *B. oleracea*, and the *Ruta-baga*—that is, all the blue thick-leaved Brassicas—while in England the *Ruta-baga* is called the Swedish Turnip. A tabular view of the different vernaculars may prove to be useful:

French.	English.	American.
Chou Cabus,	Cabbage,	Cabbage.
Chou de Milan,	Savoy,	Savoy Cabbage.
Choux à Grossescotes,	Portugal Cabbage,	Portugal Cabbage.
Chou de Bruxelles,	Brussels Sprouts,	Brussels Sprouts.
Choux-verts,	Borecole or Kale,	Borecole or Kale.
Chou-rave,	{ Turnip Cabbage or	{ Kohl-rabi.
	{ Kohl-rabi,	
Chou-navet,	{ Turnip-rooted Cabbage	{ Ruta-baga.
	{ or Swedish Turnip,	
Chou-fleur,	Cauliflower,	Cauliflower.
Navet (or Chou-navet),	Turnip,	Turnip.

Cornell University.

### Plant Notes.

**POPULUS ALBA BOLLEANA.**—It is with extreme regret that I see this handsome variety of *Populus alba* failing year by year on our grounds. At one time it was thought that it would be an exceedingly valuable shade-tree for street-planting purposes in the northern towns of Ontario. A number of trees were planted on our grounds here eight years ago. They grew with great rapidity for five or six years, and were very striking and, I may say, beautiful, when suitably situated. Out of about a dozen specimens on the grounds there is not a single healthy one to-day. The causes which have brought about this sudden decline are (1) severe winter cold without snow protection, (2) borers, (3) fungous diseases. It is difficult to say which factor has caused most injury to the trees. I am inclined to think that the order I have placed them in is probably correct. It is true that borers are exceedingly active in their attacks upon Bollé's Poplar—much more so than upon *P. alba*—and their presence seems to have a more directly injurious effect. Low temperatures cause the bark to split, branches to die off, and a general debility. Trees on sandy loam or loam and clay exhibit little differences in behavior.

Central Experimental Farm, Ottawa, Canada.

John Craig.

**CROCOSMIA AUREA IMPERIALIS.**—This plant has an interesting history, the variety having been evolved by selection from the type some ten years since by Herr Leichtlin. About the same time a similar variety was flowered at

Kew from some corms received from south Africa. Apparently nature and Herr Leichtlin had been working on the same lines. The production is certainly a most distinct and beautiful form of *Crocoshia aurea*, being double the size of the type in flower. These have wide segments, are about three inches across and a tawny reddish orange color, the reverse and buds being much brighter in hue. It is much the handsomest and largest of any of the attractive family of *Tritonias* and hybrid *Montbretias*. Whether it is hardy or not I do not know. The *Montbretias* only have been tried here, but have never survived in the open. It is possible and probable that they would do so if protected from wet, as are other Cape bulbs.

Elizabeth, N. J.

J. N. Gerard.

### Foreign Correspondence.

#### London Letter.

NEW plants were less numerous than usual at the last meeting of the Royal Horticultural Society. Orchid fanciers were specially interested in a new bigeneric hybrid of Veitchian origin, namely, *Epilælia radico-purpurata*, the result of crossing *Epidendrum radicans* with *Lælia purpurata*, the former being the mother parent. The habit and leaf characters of the hybrid resemble the *Epidendrum*, the influence of the *Lælia* being evident only in the flowers, of which there were two, borne on the apex of a slender terminal scape. Each flower measured nearly three inches across, and the segments were rotate, the petals ovate, wider than the sepals, the lip pandurate and flat; the color was a light russet with a zone of magenta surrounding a patch of bright yellow on the lip. The plant is of greater interest to the botanist than the cultivator. Messrs. F. Sander & Co. exhibited *Angræcum Eichleri* in flower. It has an elongated or creeping stem bearing two rows of ovate leaves, while the flower is not unlike that of *A. virens*. The same firm exhibited a beautiful variety of *Vanda Hookeriana* under the name of *superba*, and a plant bearing one enormous flower of the rare *Masdevallia Gargantua*. Messrs. Low & Co. sent a plant of their new *Bulbophyllum Claptonense*, which is a near ally, if not only a form of *B. (Sarcopodium) Lobbii*.

*Sedum maximum purpureum*, shown by T. Ware & Son, is an extraordinary plant, exactly like the type, but wholly of a dark chocolate-purple color, almost the color of the purple beet. Although it did not obtain a certificate it is a plant that will find favor for bedding purposes. *Rosa rugosa atropurpurea* is a seedling which originated in the nursery of Mr. G. Paul. It is distinct in the small size and crinkliness of its leaves and in the rich velvety crimson color of its flowers. A hybrid *Clematis*, said to be from *Viticella* and *Integrifolia*, also from Mr. Paul, although not brilliant, is likely to find favor on account of its shrubby habit and terminal clusters of purplish pink nodding flowers two inches across. *Heliopsis Pitcheriana* received an award of merit and was much admired, the rich orange-yellow of its flowers and their substance being exceptional. A pure white-flowered *Gladiolus* of the *Gandavensis* group, and named *White Lady*, also won favor. It is among *Gladioli* what the *White Watsonia* is among *Watsonias*. Messrs. Sander & Co. exhibited an imposing group of this plant, the flower-spikes being over five feet high, copiously branched and crowded with lovely snow-white flowers. They also sent fine examples of *Lilium Henryi* and *Exacum macranthum*.

*Hibiscus Syriacus cœlestis*, with flowers of a rich mauve-blue, and a blotched one called *Painted Lily* were awarded certificates, the blue form being greatly admired. *Veronica la Seduisante*, one of the *speciosum* section, is a beautiful variety with large erect spikes of rich purple flowers. *Eucryphia pinnatifida* was also well shown. This plant is of special value, in this country at any rate, from its habit of flowering late in July, a comparatively flowerless period so far as trees and shrubs are concerned. The

Fig. 42.—*Rosa setigera*.—See page 320.

*Eucryphia* is beautiful at Kew now. A bunch of flower-branches of the Spanish Broom, *Spartium junceum*, served to remind of the glory of this shrub. I lately saw some grand bushes of it at and about the railway station at Taplow, near Windsor. Indeed, the display made by this plant there is a startling revelation to any one seeing it for the first time. Taplow is the nearest railway station to Dropmore, of conifer fame.

New Tea Roses were shown by Messrs. W. Paul & Son, the best of them, to my taste, being a rich crimson well-formed flower named Francis Dubrieul, two equally striking pinks named Madame A. Chatenay and Grand Duc de Luxemburg, and a fine white named Empress Alexandra. The lovely *G. Nabonnand* received an award of merit. *Godetia gloriosa*, shown by Dobbie & Co., is a new variety in the way of *Lady Godiva*, but colored rich crimson, in effect like *Crimson Rambler Rose*. Sweet Pea Pink Cupid was shown by Atlee, Burpee & Co., Philadelphia.

**CACTI.**—We have now a National Cactus Society, composed of cultivators of Cactaceous plants, who are more numerous in England than formerly. The society's annual exhibition was held this week at Westminster, and, although the muster of plants was not large, it was most creditable, the collections generally showing good cultivation. Cacti will stand rough treatment better than most plants, but not without showing it, and careful cultivators who appreciate Cacti keep them well groomed, so that none of their attractions are sacrificed. The difference between a carefully grown plant and a roughly used one of such as *Pilocereus senilis*, *Echinocactus Grussoni*, *E. Wislizeni*, etc., is most marked. Phyllocacti, under the careful cultivation of Messrs. J. Veitch & Sons, are very much superior as garden plants to what one usually sees. I call attention to this matter because collectors and packers of these plants in the United States, the source of most of them, appear to be careless of bruising them. I have seen collections of them arrive in England in a most deplorable state from this cause. The Secretary of the National Cactus Society is Mr. C. A. Blogg, Brighton Road, Croydon. Messrs. Cannell & Sons are the only nurserymen who stock a collection of Cacti here.

**CRINUM WOODROWI, BAKER.**—This new species has lately flowered at Kew, whither it was sent a few months ago by Mr. Woodrow, of Poona, Bombay. It has a large ovate, smooth-skinned, brown bulb, without any distinct neck, and broad glaucous leaves not unlike those of *Crinum giganteum*, and a stout scape two feet high bearing an umbel of about a dozen flowers, which have an erect slender greenish tube four inches long and narrow oblanceolate, pure white segments, elegantly recurved, and of the same length as the tube. The stamens are about half as long as the segments. The bulbs were sent for *C. brachynema*, which is peculiar to the Bombay Presidency, but which is distinct from the new one in its narrower leaves and smaller flowers, and differs from all other *Crinums* in having stamens no longer than the tube—that is, the flowers are thrum-eyed. It is a handsome garden *Crinum*. A figure of it will shortly appear in *The Botanical Magazine*.

**KEW HAND-LISTS.**—A list of all the tender Monocotyledons cultivated at Kew is the most recent publication emanating from the Royal Gardens. It includes all except Orchideæ, of which a separate list was published last year, and consequently large groups of plants of more or less garden interest are enumerated; that is, *Seitamineæ* (Gingerworts, Musas, etc.); *Bromeliaceæ*, of which Kew possesses over 250 species; *Liliaceæ*, *Amaryllideæ* and *Irideæ*, among which are many of those plants popularly known as Cape bulbs, Aloes, Agaves, etc.; *Palmæ*, no less than 400 species of this order being in cultivation at Kew; *Aroideæ*, which are nearly as well represented as the Palms; *Pandanads* and *Bamboos*. So far as cultivated plants are concerned, these Kew Hand-lists are more trustworthy in regard to nomenclature than the *Kew Index*, the latter great work being an index to the names that have been given to plants

rather than a critical revision of them, whereas the names used in these lists are in almost all cases those which Kew has decided to adopt. It is intended to eventually accomplish a complete enumeration of all the plants cultivated at Kew, and this means practically all plants that are capable of cultivation in England both out-of-doors and under glass.

### The Vegetable Garden.

**THIS** summer is characterized by a great deal of sunless weather, and the rainfall has been several inches above the average. Artificial watering has been unnecessary throughout the season, and the frequent and copious drenchings of the ground and the luxuriant growth of the plants have made it difficult to keep the weeds in check. Hoeing and cultivating of the wet soil has not been possible, and a good deal of hand weeding has been necessary to keep the vegetable-beds clean. When any hoeing is done all weeds should be raked off the same day and wheeled away to the rubbish pile. Some kinds are hard to kill, as Purslane and Chickweed.

Most vegetables have done well this season, excepting Sweet Corn and Tomatoes. The former has been later than usual in maturing and lacks flavor, and high winds and rains broke down the stalks about the middle of July. Tomatoes thus far have ripened slowly and cracked badly, and those lying on the ground have a poor chance to color at all. The plants trained on trellises or poles need to be looked over once a week and to have surplus laterals and decaying foliage cut away and any leaves which keep the sunlight from reaching the fruit. Good sorts tried this year for the first time are New Imperial, Honor Bright and Autocrat. Plants for family purposes to fruit from November onward are now quite stocky in four-inch pots. At present we grow in the open air, and will do so until the middle of September. A pinch of seed sown now will give ripe fruit early in January.

All members of the Brassica family are doing finely this season, and no better weather could be wished for them. Late plantings of Savoy Cabbage and Curled Borecole are still seasonable, and both will give nice heads for cutting. Cauliflowers are benefited by a soaking of guano or cow-manure water after a heavy rainfall; the ground should be stirred whenever it dries out sufficiently. Squashes are doing specially well. If the ground is heavy and retentive of moisture it is a good plan to lay a piece of slate or a shingle under the fruit; this may also be done with Melons, which are now setting and swelling an extra-good crop, but need some hot dry weather to ripen them and give them the proper flavor. Eggplants still need constant watching from the attacks of potato-bugs, and they are greatly benefited by a scattering of chemical fertilizer or a soaking of strong liquid-manure. Onions will soon be sufficiently ripened to pull up and dry; the hoe is worked through them frequently, and any weeds near the bulbs are carefully picked out by hand. No vegetable better repays extra attention than Onions. To produce the finest bulbs liquid-manure is necessary, and the bulbs of plants treated with it are double the size of those not receiving any fertilizer or manure-water at all. The best bulbs are those of Prizetaker, Ailsa Craig and Cranston's Excelsior. All these are sound, good-keeping sorts.

We sow Lettuce until the end of September. Ground vacated by Onions toward the end of the month will give good heads before winter. We find Deacon, New York, Sutton's Cabbage, Salamander and Big Boston excellent varieties for late sowings. To winter in frames we still find nothing better than White Tennis Ball. A last sowing of Endive is also now seasonable; plants of earlier sowings will need tying up loosely by the tips of the cone-shaped leaves to blanch. Radishes may be sown for several weeks yet, those of the French Breakfast type being preferable. This is a good time to make a late sowing of Purple-top Munich or White Globe Turnip, as well as of Ruta-bagas. About September 1st is as early as we generally sow Prickly Spinach to stand out in winter.

Celery has reveled in the recent moist weather and is growing luxuriantly. Most of its growth will be made, however, between now and the end of September. The earliest batch is being blanched by means of boards, which is a superior method to earthing up with soil, as is done with the winter supply. Celery is a gross-feeding plant, and after heavy rain-falls a few barrels of liquid-manure water will materially improve the plants. So far we have seen no signs of leaf-rust, but this is more likely to appear when cooler nights with

heavy dews are succeeded by hot bright days. We go through the benches as soon as the ground dries sufficiently after watering and lightly stir the surface soil. It is unwise to stir it to any depth, as, owing to the moist summer, the roots are nearer to the surface than usual. This applies to many other plants as well as to Celery. Leeks enjoy similar treatment to that given to Celery, and doses of liquid-manure of good strength are now given them once a week.

Cucumbers need to have all ripe fruit removed to keep the plants in good bearing condition. Plants of the English frame section under glass take large supplies of water and frequent doses of stimulants, and require some shade, such as white-wash on the glass. Parsley, if grown to be lifted for a winter supply, should be thinned out to a foot apart, the best-curved plants being selected for the purpose.

It will soon be time to collect manure for the early Mushroom bed. Sometimes in the rush of spring and early summer work the old beds are not cleared off; wet days should be taken advantage of to do this work, and the old material is useful for mulching as well as for mixing with loam for bedding plants, or for lightening up heavy land.

Taunton, Mass.

W. N. Craig.

### Some Hardy Perennial Plants.

THE genus *Echinops*, or Globe Thistle, is not a very large one, but it contains a few species that are worthy of a place in our gardens. They are perfectly hardy and grow and thrive in any good garden soil, but for the best effects they ought to be massed near some bright yellow flowers, such as the early Sunflowers, when their globular heads show to better advantage. One of the species in bloom now is *E. comutatus*, often found under the name *exaltatus*. It is a vigorous-growing plant, and reaches to a height of five or six feet or more. The stems terminate with large, round whitish flower-heads, which are quite conspicuous, and are well clothed with large pinnatifid thistle-like leaves, downy beneath and rough with hairs on the upper side, and margined with small sharp spines.

Bees are especially fond of the flowers of this plant, and it would seem to be a useful plant for those who have an apiary. Probably the best species in blossom now is *Echinops Ritro*. This desirable plant is an old-time inhabitant of gardens and is a native of the south of Europe. It never attains much more than three feet in height. The intense blue round flower-heads are always attractive and noticeable. The leaves are also pinnatifid and downy beneath. The neat compact habit of this attractive species makes it a desirable border plant. Another species of desirable habit is *E. sphaerocephalus*; it grows from three to four feet high and has pale blue flower-heads. The Globe Thistles produce seeds abundantly, and young stock is easily obtained from seed, or the plants can be readily increased by division.

The Sea Hollies, or *Eryngiums*, are umbelliferous plants and are remarkably distinct from any other plants in bloom now. Some are quite hardy and are especially attractive and handsome for the beautiful blue of the stems and leaves. *E. amethystinum*, as it is grown here, is slightly over two feet in height, and bears amethyst-colored flowers in globose heads abundantly. In an open, sunny position it makes a handsome border plant. Another vigorous species, and which grows slightly taller, is *E. giganteum*. It is much-branched and the blue flower-heads are ovate in shape. Other equally handsome species now in bloom are *E. dichotomum*, *E. Bourgati* and *E. campestre*.

*Podophyllum Emodi*, a desirable hardy herbaceous plant from the Himalayas, is comparatively rare in cultivation. This interesting plant belongs to the Barberry family. When in bloom it is quite ornamental, but attracts most attention when its large ellipsoid scarlet fruits are ripening. I exhibited a few weeks ago some fruits, with the leaves and stems attached, at a Saturday exhibition of the Massachusetts Horticultural Society, and a first-class certificate of merit was awarded. The plant is quite hardy here and grows in slightly moist and shaded positions. The plant from which the fruits were taken was raised from seed four years ago. The herbaceous stem is about a foot in height, has two orbicular leaves which measure six to nine inches across and have from three to five lobes. The cup-shaped white flowers are solitary, axillary, or slightly raised above the axils, nodding, and measure slightly more than one inch in length. *Nicholson's Dictionary of Gardening*, *Robinson's English Flower Garden*, Hooker and Thomson's *Flora Indica* all give the measurement of the fruit as from one to two inches long. The fruits on our plant measure three and a half inches in length and slightly more

than six in circumference. Hooker and Thomson in their *Flora Indica* state that *Podophyllum Emodi* is a remarkable plant and one of the earliest spring flowers in the Himalayas, and that the pulpy, tasteless fruits are edible.

Harvard Botanic Garden, Cambridge, Mass.

Robert Cameron.

### Seasonable Suggestions.

ALL bulbous plants that have been at rest during the early summer should now be looked over, as it is time to pot most of them. We are now putting all the stock of *Freessias* into pots and pans. They will soon begin to make roots if potted, and they never can be in flower too early. It requires early potting and good culture to get *Freessias* in bloom by Christmas. It is almost impossible to have the soil too rich for these bulbs, and to have really good flowers liberal supplies of liquid-food is necessary after they have begun to grow. We prefer to grow them in pots or deep pans, as they are available then for house decoration. But the best plan, where cut flowers only are required, is to put the bulbs in boxes, and when the shoots are well up to place short twigs of birch between them to keep them erect. We box all small bulbs to grow on to flowering size when it is needed to add to the stock of this fine winter-flowering bulb.

*Lachenalias* need potting at this time also. They come from the same country, south Africa, and have been at rest for the last three months in the pots in which they grew. It will be found on examination that there are signs of root-action starting, and the sooner the bulbs are put in new soil and given moisture the better will be the results. There seems to be a growing liking for *Lachenalias*, and there are some fine varieties now in commerce, the result of crossing the various species. If it is desired to purchase *Lachenalias*, it is wise to order early. The Dutch growers last year could not supply many of the kinds, the demand being larger than the supply, especially of the larger-flowered varieties of recent origin. We find that *L. pendula* makes a fine companion plant for the Roman Hyacinth; it flowers at the same time of year, and adds variety to the prevailing white of the Hyacinths. *Lachenalias* can be grown in the coolest of houses; they are averse to heat in every case, and a shelf in a Violet-house, where they can be free from frost and have plenty of air, are conditions they delight in. *Lachenalias* make the best display when potted in five-inch pots. We have had them in pans, but to see them and use them to the best advantage pots are preferable, filled with rich soil. When planted they should be placed in a cool frame until frost comes, when they may be removed to the greenhouse.

To have Roman Hyacinths early we must plant early; in fact, as soon as it is possible to obtain the bulbs. The largest bulbs do not always produce the most flowers, but, preferably, those that are hard and well matured. It is the custom with some growers to rush the crop of bulbs on the market to secure early sales at the risk of maturity. This can be easily detected in the bulb, as it is then not hard and shows signs of premature ripening off at the crown. These delicate and fragrant flowers are in demand as early as Thanksgiving-time, and the bulbs should be planted as soon as they can be obtained.

*Mignonette* is desirable in winter, especially as it is never seen to so good advantage as when well cultivated in a house with a suitable temperature. Our summers are much too hot to favor the growth of good spikes, and it is well to sow some seeds of an approved strain now to have it when flowers are most scarce, just when *Chrysanthemums* are past. *Mignonette* likes a cool temperature, say a maximum of fifty degrees, such as a Violet-house will furnish, and a deep soil. A bench at least a foot deep is best, and though this may seem a great deal of soil, we find it is useful in spring, when hot-beds are being made up for early vegetables, to have the soil from the old spent *Mignonette* beds ready to hand already warm and in condition for sowing seeds or transplanting vegetables. There are many good strains of *Mignonette* now, as Allen's *Defiance* and Sutton's *Giant*. We have grown the latter for a number of years and it never has disappointed us. Both these kinds seem to be fine selections from *Machet*, which is the best for outdoor culture.

A word may be said for *Browallia speciosa major*, which has proved desirable for pot culture in winter. The older *Browallias* were small-flowered in comparison with this variety, and not very desirable garden plants, but this novelty has all the qualities that go to make a good winter-flowering plant, either for use in pots or as cut flowers. A packet of seeds sown now will make nice plants for winter use and will flower along until late spring.

South Lancaster, Mass.

E. O. Orpel.

### The Annual Species of *Coreopsis*.

**C**OREOPSIS is a genus of common American plants, of which no less than seventeen species are found widely distributed through the Mississippi Valley and the southern states. Plants of this genus are thrifty, vigorous growers, generally hardy, and when cultivated do not demand the care required by many delicate species. This genus does not appear to have received much attention from American gardeners, and our seedsmen have heretofore offered few named varieties, but in Europe, where the plant is not indigenous, it is deservedly popular and many varieties have been bred and offered.

The larger number of the species are annuals, but some are biennials or perennials. In this northern climate the seed should be sown under glass in March, the young plants potted off when about an inch high and planted out in May. They begin to flower in June, and continue to bloom profusely till frost-time.

The annuals are collectively known, in distinction from the perennials, as *Calliopsis*. Among these the best known are *Coreopsis tinctoria*, *C. cardaminefolia*, *C. coronata* and *C. Drummondii*. The last two are low-growing species, bearing the flowers on long pedicels above the rather thick foliage. They do not make as good an effect in massing as some others.

Probably the most widely cultivated species is *Coreopsis tinctoria*. This is a pretty, slender-growing plant, much branched, and with very narrow linear leaves. The type has yellow rays with a purple-brown blotch at the base, but there are numerous variations, in some of which the entire flower is purple-brown. *Coreopsis* is better adapted for massing than for planting singly. *C. tinctoria* makes a good background for an herbaceous border. Some of the dwarf varieties, differing from the type, are erect and shapely and bear their flowers in a close mass. These make a pretty border for a bed. Variety may be added by proper selection of colors. *C. tinctoria*, cut with long stems, makes a pretty bouquet for a mantelpiece or large dining-table. I have seen a pleasing effect obtained by cutting the stems long and placing them in a loose bouquet in a large vase. They fall over the sides of the dish and readily suggest both the lack of compactness which characterizes the growing plant and its natural gracefulness and delicacy.

#### The Vitality of Seeds.

To the Editor of GARDEN AND FOREST:

Sir,—Referring to Mr. Hatfield's article on the vitality of seeds, I may add to the list the graceful and showy *Ipomœa coccinea*. Fully as interesting are the unfavorable conditions under which seedlings will thrive. A trellis around the stump of a tree was covered last year with this *Ipomœa*, which, as usual, self-sowed its seed. Some fell into a diminutive crack in the top of the stump, and this year two small plants about a foot or so high are flourishing without any soil to grow in. They did not even seem to feel the need of water before the last rains set in.

A neighbor of mine picked a seed-pod of *Cobæa scandens* late in the fall and allowed it to ripen in the house during the winter. On planting the seeds the following spring the plants came up with variegated foliage and retained the variegation throughout the season. The ripening of the seeds in the house rather than on the vine caused, perhaps, a certain diseased condition of both seed and plant.

Bergen Point, N. J.

L. C. L. Jordan.

#### Range of Pacific Coast Lilies.

To the Editor of GARDEN AND FOREST:

Sir,—Since writing the series of articles on Pacific coast Lilies, which have appeared in GARDEN AND FOREST, some interesting facts regarding their distribution have come to my notice. The range of *Lilium pardalinum* extends to Julian, in San Diego County, California, well toward the Lower California line. This gives this species a distribution from Lower California to British Columbia and to Lake Winnipeg, truly an immense range.

Hitherto I have only known *Lilium Washingtonianum* as existing in the Sierra Nevada and Cascade ranges. I now have definite knowledge that where the Rogue and Klamath rivers break through the Sierra chain, *L. Washingtonianum* follows them to the sea. They are common in the Siskiyou range. *L. Washingtonianum* follows the Trinity, the great

southern tributary of the Klamath, and I have at hand specimens of it collected only thirty miles from Eureka, in Humboldt County, California. At this point *L. Washingtonianum* makes a wonderful growth, being rarely less than seven feet high, and the flowers are pink. Some stalks were fourteen feet high.

*Lilium rubescens*, its near relative, is found at points not over fifteen miles south, and I think that I can safely say that I have determined the northernmost extension of the one and the farthest southerly extension in the Coast Range of the other.

Ukiah, Calif.

Carl Purdy.

### The Sycamore Blight.

To the Editor of GARDEN AND FOREST:

Sir,—Observing Mr. Olmsted's request in GARDEN AND FOREST of July 21st concerning the blight of the Plane-tree, I report from this vicinity that the native *Platanus occidentalis* suffered badly. Many appeared in June quite dead, but some are now thrusting out new sprouts which may or may not mature. I know of but eight trees of *P. orientalis* about here. Four of them are vigorous trees. These four did not suffer at all. The other four are weak trees, and did suffer some in June, but less than the natives did, and have now substantially recovered.

When *Platanus orientalis* is to be planted I think a small vigorous tree should be selected, good ground chosen and kept heavily top-dressed for several years. Trees treated in this way flourish for a dozen years at least. What they do later is beyond my experience.

New Bedford, Mass.

Thomas M. Stetson.

### The Elm-leaf Beetle.

To the Editor of GARDEN AND FOREST:

Sir,—I have occasionally read in your journal of machinery for spraying trees on a large scale as a remedy against insects and fungi. Would you advise a borough to purchase a machine or to employ some one to undertake the spraying of the trees by contract? If you advise the purchase of a machine, what particular pattern would you recommend, what is its probable cost, and where could it be obtained?

Morristown, N. J.

S.

[These questions cannot be answered categorically without some further knowledge as to what our correspondent proposes to accomplish. The best advice we can give him is to get the *Year Book of the Department of Agriculture* for 1896 and study the article by Dr. L. O. Howard on The Use of Steam Apparatus for Spraying. There is no doubt that a steam engine can be made useful for the protection of shade-trees, and that it is the most economical way to treat a large number of trees, and the letter which follows this reply gives an account of one fairly successful experiment in this direction. A very excellent apparatus is now used in the public parks of this city, which was constructed under the supervision of Mr. E. B. Southwick, the entomologist of the department. Some such apparatus ought to be at the command of every city and town which takes any interest in its shade-trees. Dr. Howard's article goes into the details of the subject, gives the history of many attempts which have already been made in this direction, with the reasons for their failure when they have failed, and it is full of suggestions which cannot but be useful to any one who takes any serious practical interest in the matter.—Ed.]

### Our Street Trees and the Elm-leaf Beetle.

To the Editor of GARDEN AND FOREST:

Sir,—The question of preserving our street trees from insect devastation is becoming quite a serious one in some of our cities, especially where the Elm-leaf beetle is most active. Spraying the large trees is rather expensive, and more or less difficult, but can be readily done if steam power is employed, as has been demonstrated in several cities. Most city governments are poor, however, and many persons seem to believe that in some way or other the trees will take care of themselves, or that the beetles will be kept in check by means of natural enemies without man's assistance. It is only when trees actually die from the effects of attack by the beetles, and such object-lessons as may be found in Milford, Norwalk and

New Haven come to the notice of the people, that remedial action is taken.

During the spring of 1896 the city authorities of New Haven made an appropriation for spraying the Elm-trees. The work was placed in charge of Mr. T. B. Kelly, Superintendent of Parks, who prepared an outfit for the purpose and used a four-wheeled road-engine connected with hose to an ordinary street-sprinkler. The machine worked well, and many of the large and beautiful Elms of the city were sprayed, not only once, but two and three times. The work began early in May, and a great many cankerworms, which are so destructive here, were killed. The park and street trees in the central part of the city were first treated; then the trees along the streets extending radially from the centre, as much ground as possible being covered before a second application was necessary. The people residing in the sprayed district were generally willing and eager to coöperate, and did so by treating or having treated, at their expense, the trees on their own grounds, and often the street trees in front of their residences. The foliage of the Elms throughout the sprayed area was fairly well preserved for the season. There were, of course, a few exceptions—some of the trees being injured by cankerworms before the poison was applied—and here and there a tree was injured by the poison itself, either from being improperly prepared, or more probably from not being kept properly agitated in the tank during the process of spraying. Many trees in the outskirts of the city, and probably more than one-half the total number of trees within the city limits, received no treatment during 1896. It is needless to say that these trees were injured, but the injury was less than that received by the same trees this season. Both the cankerworm and Elm-leaf beetle have come and gone, and the trees in the central part of the city that received thorough treatment during 1896 have retained their green leaves and are comparatively free from all insects. This personal observation is corroborated by Mr. Kelly. Outside the district sprayed in 1896, the leaves of many magnificent Elms were riddled by cankerworms in May; some were stripped of every leaf. Later, the Elm-leaf beetle attacked the remaining portion of the partially consumed leaves, soon turning the trees from green to brown. It will be interesting to note the appearance of the trees next season, to see if those sprayed in 1896 are as badly affected as the others; or, in other words, how long it will take for the region again to become badly infested where the work was done thoroughly.

It occurs to me that treating half the trees in a season, and the remainder the following year, may possibly be an effective and economical way to preserve the foliage of our street trees. I am not aware that this method has been thoroughly tested. I speak of it only because observations here during two seasons point in that direction. Of course, the spraying must be well done each year, and a little overlapping each time would help make it a more complete success. Trees along the boundary between the sprayed and unsprayed districts might need spraying every season. Even then it would be much less expensive than treating all the trees, if that were possible, and doubtless would kill the insects in far greater numbers and keep the trees in a better average condition than spraying the same trees every year, where a portion only can receive treatment. Both the cankerworm and the Elm-leaf beetle would be killed if the spraying was begun early in the season.

I would like the opinions of entomologists, through your columns, regarding the practicability of preserving the foliage of our street trees by the method of treatment which I have suggested.

*A Few Familiar Flowers: How to Love Them at Home or in School.* By Margaret Warner Morley. Boston: Ginn & Co.

In spite of its rather sentimental subtitle, this is a book of practical value in the suggestions it makes for the proper methods of what it has become the fashion to call "nature study." It is not a book for students, but for teachers, and, we may add, for young teachers, giving them hints to make them skillful in helping children to look for themselves and think for themselves. Only five plants are spoken of—the Morning Glory or Bindweed, the Jewelweed, the Nasturtium, the Geranium and the Hyacinth—and the object is not primarily to teach children how to add some meaningless names to the different parts of a flower, but to help them discover and understand the func-

tions and uses of the various parts of the flower and the relation of its structure to its uses. The primary purpose is "to enable the child to feel that the flower is alive, that it does things, and is an individual like the rest of us." To this end no attempt is made to accumulate a great mass of facts, but to hold the interest and stimulate the curiosity of the pupil to investigate the life-story of a plant for himself and become thoroughly acquainted with it. The adaptation of the Bindweed-flower to cross-fertilization by bees is set forth at the very outset. It is shown how the color, form and position of the flower helps the bee in its search for nectar, and how the bee helps the plant in placing the pollen where it needs to go in order to form seed.

No one can read the book without being convinced that by a study of these few plants, under the guidance of a wise instructor, a child can learn more about the essentials of plant-life than he can by pulling it to pieces and labeling its different organs. Even a young child can appreciate the vital facts in the biology of a plant, and if his investigations are properly directed he will find that in every organ and in the position and attitude of every part of the plant there is order, and that each organ has a distinct duty which it conscientiously performs in the interest of the whole organism. The study commences with the flower, but the other portions of the plant are taken up in turn, and it is shown how the root and fruit can be made quite as interesting as the flowers. The book contains a little cheap moralizing here and there which could as well be omitted, but upon the whole it is a performance of genuine merit, and we could wish that every young teacher who thinks that she (for the feminine pronoun is invariably used in this work when the teacher is alluded to) has an adequate knowledge of botany because she can give the Latin names to all the common plants which come in her way, would carefully read these simple lessons, or rather would take these five plants and study them in connection with the text of this little volume.

## Notes.

The Sweet Pea, Queen Victoria, was the most admired flower on exhibition at the Springfield show. It was seen at its best in the collection of Mr. Hartzell, who exhibited the Eckford set of 1896.

Professor H. V. Wilson says that no visitor to Wilmington, North Carolina, can fail to notice what an admirable street-tree the Laurel Oak makes. Its straight trunk, symmetrical top and moderate size give it an elegance of shape well suited to city streets, and the impression of finish is heightened by the glossy aspect of the foliage.

Dr. Lintner, State Entomologist of New York, has prevailed upon the Common Council of Albany to purchase a steam sprayer for use against the Elm-tree beetle in that city. The pest has almost destroyed many beautiful trees in the parks and residential streets, so that they are naked as they are in winter. It is to be hoped that this prompt action will save many of the trees.

The Russian Apricot, Early Montgamet, is being planted to a considerable extent in central New York, where it is considered not only superior to all the Russian Apricots, but to every other variety of that fruit for planting in northern orchards, when its hardiness, productiveness and general quality are considered. Mr. S. D. Willard, of Geneva, an admirable authority, thinks that it can be grown with success wherever the Peach will thrive.

Our native Prairie Rose, which is figured on another page of this issue, and which has only recently found its way in any considerable numbers into American gardens, is beginning also in Europe to find the appreciation which its merits deserve. In the current number of *The Garden* it is stated that a large mass of this Rose in Kew was making a most effective display in the last week in July, and that, in spite of the fact that it lacks fragrance, it was there considered one of the most attractive of the hardy shrubs which flower at that season.

The autumn meeting of the American Forestry Association will be held at Nashville, Tennessee, on the 22d of September, with papers by George B. Sudworth, Colonel J. B. Killebrew, J. A. Holmes, H. A. Hazen, D. W. Baird and F. H. Newell. It

has been arranged that an excursion, including the members and their friends, shall leave Washington on Thursday, September 16th, for Asheville, North Carolina, and a visit to the forests of Mr. George W. Vanderbilt, under the direction of Dr. Schenck. The party will reach Lookout Mountain on Saturday evening and Nashville on Monday morning, September 20th.

A late number of *The Garden* contains a beautiful colored illustration of the Bicolor Daffodil, Ellen Willmott. This is one of Mr. Engleheart's creations, and it is a seedling from John Horsfield fertilized with the pollen of a selected form of *Narcissus variiformis*. The plant is rather dwarf, but it throws up a tall stout stem which carries a flower of remarkable substance, symmetry and color. The white lobes of the perianth slightly overlap each other and they bend forward slightly at the tips. The trumpet is of a clear yellow and of just the proper size to suit the cup. It flowers early, a little in advance of its seed parent, whose robust constitution it seems to have inherited.

*The American Florist* last week reproduced the photograph of a hedge of the Crimson Rambler Rose, which shows that the vigor and hardiness of this plant, together with the abundant way in which it produces its brilliant flowers, adapt it in a remarkable way to such a use. The hedge pictured is 135 feet in length and it is on the estate of D. Willis James, Esq., Madison, New Jersey. Mr. William Duckham, the gardener, set out the plants from pots where they had been grown on their own roots in May, 1896, and in June of this year, when the photograph was taken they were making a magnificent display. Shoots were tied to a wire support stretched between iron posts, and there were some fifty clusters of bloom to every linear foot.

At the annual meeting of the Vermont State Horticultural Society, Professor W. M. Munson called attention to the fact that although individuality is as strongly marked among trees of the same variety as it is among animals of the same breed, yet not one nurseryman in a hundred gives any heed to this fact when he begins to propagate. Scions are taken from the most available source, which may be a nursery row or a convenient tree of the variety needed, and with no reference to individual characteristics. Professor Munson has no doubt that this neglect in the matter of selection has more to do with the failure of orchards than any other one condition. It is one potent cause of the so-called "running out" of varieties. Breeds of horses, cattle or swine treated in a similar way would also run out very soon.

At a recent exhibition of the Royal Horticultural Society much interest was excited by a new hybrid Orchid raised by Messrs. Veitch & Sons, and called *Epikelia* × *Radico-purpurata*. As its name indicates, it is the result of crossing *Epidendrum radicans* upon *Lælia purpurata*, and although it is not the first time that such dissimilar genera have been united, it shows the striking possibilities in the way of new groups in this remarkable family. The seed of the *Lælia* fertilized by the *Epidendrum* was sown in September, 1892, and the seedling flowered in July of the present year, and the flower again, as well as the plant, shows the strong individuality of the pollen parent, as it did in the case of the hybrid between *Epidendrum* and *Cattleya*. The plant has a slender reed-like, root-bearing stem, and the flowers are borne on a slender peduncle fourteen inches long. The color is rich orange-scarlet, base and centre of the lip lemon-yellow, margined with light reddish purple. It is two inches across, with lanceolate sepals, ovate petals, broadly ovate lip and a crest with three yellow keels.

Professor M. V. Slingerland writes to *The Rural New-Yorker* that the San José scale was discovered at Cornell University last April on some of the ornamental trees and shrubs, and in May before the hibernating scales began their spring growth the bark of the trunks and larger branches were thoroughly washed with whale-oil soap, dissolved at the rate of two pounds to a gallon of water. On the 25th of June, when the scales which had wintered over had made considerable growth, every infested plant was thoroughly drenched with spray containing one part of kerosene to five parts of water. Very few of the leaves on the Dogwoods or other shrubs were injured, and a second application of the same spray was made on July 2d. The result is, the scales have been practically exterminated by three applications, but it must be understood that the spraying and washing was not done in a half-hearted way, but by a man who understands the business. This seems to indicate that the pest can be controlled by vigorous and thorough work.

Last week marked the heaviest shipments of California fruits ever sent to this city, and 105 carloads were sold. The

plums now seen in great variety are of the richest colors and largest size and maintain fair prices, but California peaches, which come at this time into direct competition with the eastern product, sell at prices so low as to allow small profits, if, indeed, any to the western grower. Choice Barlett pears are still seen, and Flame Tokay and other grapes are improving in color and flavor as the season advances. Several well-known varieties of nectarines are included among these western fruits, but in the partially ripened condition in which they arrive these do not seem to appeal strongly to popular favor among more luscious and juicy fruits.

Mr. Joseph Meehan writes us that the so-called blue varieties of *Picea pungens* are unusually beautiful this year in Germantown. These trees vary much in color, and in a collection of seedlings many individuals will be as green as the Norway Spruce, but the silvery blue of the new growth of other individuals makes them more striking at this season than almost any conifer. Both *Cedrus Deodora* and *C. Atlantica glauca* are now covered with the silvery foliage, the *Deodora* Cedar seeming to make the best display, not because the foliage is of a lighter color, but because it is more abundant. The Atlantic Cedar seems to be the hardier of the two, although both succeed perfectly well in Germantown. *Cephalotaxus Fortunei* comes through the winter in Philadelphia as well as the Yews do, rarely suffering more than a slight browning of the foliage. *C. Fortunei* forms a spreading bush with foliage of the very darkest green.

According to *The Gardeners' Chronicle*, which has been making a careful summary of the prospects of the fruit crop in the British Islands, there will be a marked deficiency in the apple crop all over the kingdom. Out of 314 reports only ten are marked as over the average, while 230 are recorded as below it. Plums, the next most important crop commercially, show even a greater deficiency, from which it is clear that for both these fruits Great Britain must rely upon foreign sources of supply for the year. In regard to small fruits the case is different, and it is worth noting here that at a recent London exhibition, one firm, Messrs. James Veitch & Sons, sent a collection of one hundred varieties of gooseberries. Of course, we can grow good gooseberries and grow them well in America, but when we read of a dozen first-class varieties of red gooseberries, as many more of green berries, not to speak of yellow berries and white ones, and of a smaller class of highly flavored berries, red, yellow and green, each containing half a dozen varieties of the first merit, we understand that in the cultivation of gooseberries this country is far behind England.

The third annual meeting of the National Apple Shippers' Association was held in Buffalo, New York, on the 5th, 6th and 7th of this month, the object being to obtain accurate reports of the condition of the apple crop in various sections of the country and to regulate the system of grading and fix standards which can be definitely relied upon by dealers. In his opening address the President, E. P. Loomis, of this city, showed the growth of the apple trade, and stated that whereas in 1889 there were produced 57,242,000 barrels of apples in the United States, in 1896 the yield amounted to 75,000,000 barrels. Of 2,558,370 barrels of this fruit exported from the port of New York last year, almost all came from New York, Pennsylvania, Ohio, Michigan, Indiana, Illinois and Missouri. The exports from Virginia are usually important, being mainly of choice Albemarle or Newtown Pippin, but last season's crop was a very light one. Mr. Loomis said that the exports of fruit, mainly apples, had grown from \$24,974 in 1850 to \$542,502 in 1870, and increased rapidly thereafter, until in 1894 \$2,299,006 represented the value of these shipments from this city alone. The apple crop for 1897, estimated from reports of the statistician and of members of the association and from other reliable sources, is said to be considerably smaller than the immense crop of last year, but equal to the average, and the largest crops this year, as would be expected, are promised in sections which produced small crops in 1896. Colorado, California and Oregon are rated at 100 per cent. for this year, or as yielding a full crop, and some of the middle western states are rated at seventy to ninety per cent. From New York state but one-quarter of a full crop is expected, and other eastern states promise from half to two-thirds of a full yield, Virginia being counted at seventy per cent. Canada is rated at forty per cent. The grading of apples, transportation and a uniform bulge for the sides of barrels were among the subjects discussed, and with the length of staves, number of hoops and size of heads already fixed for the standard barrel, not less than sixty-four and a half inches was decided upon as the bulge.

## The Planting of Private Grounds.

THIS is a season when little actual work needs to be done in gardens and pleasure-grounds. Therefore it is a good time for contemplation—for self-instruction. It is the time to judge the results of past work—to decide whether what has been achieved is good or is bad, and to examine why it is so. And it is the time to plan for the future—to decide what more shall be done, what shall be undone, and from what the enterprising hand shall be altogether withheld. Plans should be made to correct past sins of commission, to repair past sins of omission, and to guard against both for the days to come.

The great sin of commission which a study of ornamental private grounds in all parts of our country reveals, is the failure to cut out trees and shrubs which were always ill-placed or which have been rendered detrimental or superfluous by years of growth and development. Everywhere we see country places, small ones especially, which, whether viewed from the inside or the outside, are less beautiful than they might be because their plantations are too crowded. A house may well be draped and shaded; but it should not be concealed or smothered by foliage. Charming outlooks ought not to be shut off. A fine tree ought not to be hampered in its development by others less attractive. Two or three trees of equal excellence ought not to be allowed to survive so long together that the beauty of all will be ruined. A shrubbery ought not to look like a rough thicket, nor should a place be so crowded with shrubberies as to look like a wilderness. Health as well as beauty demands that foliage should not be too dense in the neighborhood of a dwelling-house, for human beings, no less than plants, need the free ministration of the winds and the sunshine of heaven. Therefore, at this season of the year, every owner of a country place, large or small, should look carefully at his trees and shrubs, and should decide whether it may not be for the greatest good of the greatest number (himself and his family included) that some of them shall be cut out.

Corresponding to this sin of omitting to use the axe when its use is required, is the sin of commission involved in planting excessive numbers of trees and shrubs. Even

when allowance is made for the need of young trees to be protected, and for the need of the planter to guard against the possible failure of some, too many are usually set out on a new place where Nature has not already supplied a superabundance. The beauty of placid open spaces of grass, the charm of far-away vistas and the dignity of simplicity in the general effect of a place are forgotten. Even when large lawns are reserved, they are generally sprinkled over with isolated plants to such a degree that their true beauty is fatally impaired. Therefore the owner of a place where planting is needed should carefully consider, before the season to attempt it begins, just where he had best put his thick plantations, and just how many—or, rather, how few—trees and groups of shrubs need to be set near his house and upon his lawn. He should have a definite scheme in mind before any work is started, and, in spite of the profuse temptations of nursery and garden catalogues, he should strictly adhere to this scheme unless definite good reasons for its alteration present themselves.

Of course, it is impossible to lay down any general rules with regard to the desirable amount or to the desirable distribution of foliage in a small country place; for each place differs from all others in the conformation of its ground, the character of its native vegetation, the attractions of its outlooks, and the tastes of its owners. For example, there are seaside situations where Nature has done scarcely any planting, and where no more is required by a sensitive eye unless, perhaps, in the way of a few hardy shrubs and vines set about the foundations of the house to make it look as though it belonged to the ground upon which it stands. On the other hand, in inland regions there are places where thick, shadowy groves of Nature's planting need only to be thinned sufficiently for the due admission of air and light and the opening of vistas. Between these two extremes lie many intermediate possibilities of beauty.

One general precept can, however, be laid down: Respect should be paid to the essential character of the country-side at large. If it is covered by trees of great size and beauty, your place will not look well if it seems to be a barren exception to the local rule of luxuriant growth. And, if it is a barren stretch of seashore, your place will not look well if you spend thousands of dollars in setting out thick groves of trees, and try to cultivate plants of luxuriant aspect better suited to the fertile soil and surroundings of some interior valley region. But even this great general rule of appropriateness to broad local conditions should not be pushed too far. Respect must be paid to the charms of variety as well as to those of harmony. In a thickly forested district, for example, fine trees should be secured; yet broad open lawns will be peculiarly attractive as a relief to the eye satiated with dense woodland effects. And, correspondingly, while many a seashore place demands no planting at all, yet if one or two good trees can be induced to grow near the house they may delight the eye much more than if they had been met with in regions where similar ones abound.

However, most people need to be more carefully warned against planting too much than against planting too little. It is extraordinary to see the energy often bestowed upon the creation of a wide lawn, and then the equal energy displayed in ruining it with a cluttered assemblage of freshly introduced plants. Everything which the spot naturally bore is cut down and grubbed up. Often even picturesque rocks, or wide low stones, invaluable as giving dignity and individuality to the place, are removed at great expense. And when at last the wide sheet of green is secured, forthwith it is broken up and frittered away by being dotted over with a hundred garden trees or shrubs.

The mention of rocks suggests another rule which may, in a general manner, be prescribed. If one or more stones, large or small, break the uniformity of a lawn, the places for possible planting are thus naturally indicated. Of course, even here planting is not always required, and it may even be injurious if a fine view is thereby spoiled, or if the har-

monious lines of other plantations are interfered with. But if the lawn is so large that a few trees or bits of lower foliage will not spoil it, and if no special reasons prevent, then the best places for them will be in association with any rocks or stones that may exist. The existence of these as alien objects in the spread of turf gives a logical reason for the presence of others. And the effect of both stone and tree will be enhanced by the association of the two. The Japanese understand this truth very clearly. There is nothing to which they give closer attention than to the grouping of trees and stones. Often, indeed, the rock or stone itself is introduced to complete an effect which seemed incomplete without it; and sometimes the desire for a stone appropriate for association with a given tree leads to its importation from some distant part of the empire. To such subtleties of artistic endeavor we have not yet attained. But two at least of our American landscape-gardeners—Mr. Olmsted and Mr. Vaux—have thoroughly understood how much beauty may be gained by the proper combination of vegetable and lithic forms. The result of their combined work may be studied in the Central Park. No features of this beautiful and individual pleasure-ground are more beautiful or more individual than its groupings of stones and foliage. And although some of its most admirable results in this direction were obtained by clothing existing rocks with foliage, in other cases the stones as well as the plants were deliberately selected and placed. The more "natural" their effect the less sure can the observer be that there is anything really natural about them, for he instinctively applies the word to those things in Central Park which are to-day most beautiful, while only the student who has inquired into its genesis can guess how often these very things are altogether the products of art.

If, therefore, a rock or stone breaks the uniformity of a lawn, the advisability of planting something in connection with it may well be considered. Of course, its size and shape and situation must determine how many plants should be set beside it, and of what sort and size they should be. If it is itself of large size, a goodly tree may overshadow it. A smaller stone will demand a smaller tree, or one or two graceful shrubs. And a ledge which spreads near the surface of the ground may demand only a prostrate shrub or some creeping plant. Vines may always be introduced, in moderation; but whether with vines or with larger plants, moderation must always be practised. The last thing that should be done with a picturesque stone is to cover it up. Its character should be enhanced and completed, not overshadowed or concealed. It should not be "planted out" by thick tall masses of foliage, nor allowed to disappear beneath heavy wreaths of trailing or creeping things. An harmonious group should be formed in which, as a rule, the stone itself should be the most conspicuous feature, or at least, speaking artistically, the central feature. How this should be done Nature will teach, if her own works are lovingly studied. The planter who has tasks of this kind before him cannot do better at this season than drive along the country roads, or wander through old meadows and open woodlands, and see with what combinations of foliage Nature adorns her huge rocks, her smaller boulders, and her low out-cropping ledges of stone.

#### The Dalles of the St. Croix, Wisconsin and Minnesota.

FOR some years a movement has been on foot to secure a reservation of about 1,550 acres on the picturesque banks of the St. Croix River for an interstate park. The nucleus of this park is a tract of one hundred and fifty acres already acquired, including some of the most picturesque scenery of that wild region which received its name from the early French voyageurs. The French word *Dalles* signifies flagstones, and the term was here applied on account of the peculiar stratification of the rocks of this

part of the St. Croix River, which, owing to their post-glacial undermining by the water and the action of frost, have fallen down in great blocks and slabs, separated along their natural, almost upright planes from the rock walls which border the stream.

A gloomy grandeur characterizes this part of the river, which contrasts delightfully with the cheerful sparkle of the upper rapids, the quiet beauty of Thaxter's Lake and the sunny interval with its scattered shade-trees, which are also features of the scene. The hills on the Wisconsin side are lofty, and the Minnesota gorges precipitous, and a fine old forest forms a boundary between the stern scenery of the embattled rocks and the quiet farm lands toward the west. Should the whole tract desired by the park commissioners be set apart by the legislatures of the two states it will include a most interesting variety of landscape, ranging from the broad lawn-like expanse of the interval to the savage features of the shadowy gorges through which the whirling stream tumbles and foams. The hope is to maintain the wild, natural features of this scene, and to preserve and enhance its native distinction by protecting it from the devastating hand of the settler, the woodcutter and the manufacturer.

Some account of the strange formations which characterize this region may prove interesting. An admirable report, published recently, contains papers by scientific men and the landscape-gardener of the park, Mr. F. H. Nutter, and furnishes numerous valuable details concerning the reservation. From this report we learn that the Dalles of the St. Croix River, situated in Chisago County, Minnesota, at the head of navigation, with certain adjacent lands, were acquired by the appropriation of \$6,000 by the Minnesota legislature in April, 1895, and ten days previously the Governor of Wisconsin approved a bill to obtain lands in Polk County of that state, along the east bank of the St. Croix, and commissioners were appointed to examine the lands and report concerning them. Since the purchase of the first 150 acres, bills have been pending before the legislatures of the two states to secure about 300 acres additional in Minnesota and 1,100 in Wisconsin, and it is to be hoped that political influence will not prevent the carrying out of a scheme so important to the welfare and enjoyment of future generations. Active-minded citizens have been working hard for this desired consummation, and great interest has been shown by the local press. A series of lectures at Taylor's Falls, Minnesota, was arranged for, to which eminent speakers gave their services, and the adjacent railways aided also. The commissioners worked with zeal, the ladies of the Twin Falls coöperated with the aldermen to help them, and the work was pushed along and public interest aroused so that it is to be hoped the future of the Interstate Park is practically assured.

The peculiar and unique character of the Dalles entitles them to be preserved from spoliation forever. The rocks which compose them are the trap or basalt which, when upheaved in vast masses and left to cool slowly under pressure, forms regular columns like those of Fingal's Cave or the Palisades of the Hudson. Here, however, where they were thrown up in lighter masses and cooled without great pressure, they form irregular angular heaps with smooth, almost unbroken cleavage. Their color is beautiful and varied, owing not alone to their mineral composition, but to the growth of minute lichens upon their surfaces, which vary in color with the dryness or moisture of the atmosphere. Sometimes they are sombre gray, and again iridescent with opaline tints. The rock angles are sharp, their faces as unworn as if they had not weathered thousands of years of storms, and they are especially remarkable for the freakish forms in which they rise into columns or monumental piles, and for the strange outlines of human faces which one detects in their irregular shapes. Holes, called wells, some of which are thirty feet in diameter, and others only a few inches wide, are found here, formed by the churning of boulders during the cascade period through which the

region passed in prehistoric days. In some of the wells the drilling rock is still found; in others it has entirely disappeared. Into one of these wells, eight feet in diameter, a pole has been thrust down thirty feet; others are choked with débris and cannot be fathomed. Of the columnar formations the Devil's Chair is the best known. This towers about eighty feet above the level of the river, in the form of a huge chair, apparently built by some giant, of roughly hewn masses of rock. Vegetation clusters about its base, and tall Pines spring from the cliffs behind it, but its smooth top is bare, like some strange vestige of the furniture of an age of Titans. The Hammer Head is a column with two grotesque faces looking in opposite directions, like a statue of Janus, and the Sentinel, or Warden, on a ledge overlooking the Narrows just below the bridge, is strangely real, lifting a stern granite profile against the sky. Other faces, in which one detects fancied resemblances to Washington or Napoleon, are found all through the region, and one, Professor Edwards tells us, is a gigantic likeness of a Ute Indian, with Pine-trees for feathers, and trailing vines for scalp-lock, while a leafless Pine branch does duty for a pipe in his mouth. On the Minnesota side of the river there are all sorts of queer rock formations, of such supernatural size and shape that they are called Devil's Bake Oven, Devil's Pulpit, Devil's Parlor, etc., but on the Wisconsin side holier emblems appear, and one of its most striking features is the uplifted image of a great stone cross, which, particularly when touched by the rays of the sunset, is a noble and impressive monument. On this bank also is found a lovely lake, a beautiful resort for canoeists.

The Indian name of the most beautiful lake of the region, Kichisago Sagi-a-gan, meaning large and lovely lake, still lingers in the name of Chisago County. Traces of early French occupation are found dating to about 1700, when the long-vanished fort St. Croix was established on a plateau below the Dalles. Near Taylor's Falls were still to be seen in 1851 the stone foundations of at least nine houses, over some of which were growing trees two feet in diameter, with hearthstones worn smooth by use, apparently a century old. This early civilization had been long extinct, however, when the pioneer of the present settlement put in claims to the Dalles in 1837. The village of St. Croix was first known by the Indian name of Caw-caw-baw-kong, which might seem to have been suggested by the warning notes of crows, but means simply the waterfall. This name is still preserved in a neighboring cemetery.

The flora of the Dalles is rich in vines and flowers that love a northern climate, and its silva consists of Pines, Firs, Cedars, Birches, Willows, Poplars, Maples, Walnuts, Elms, Ashes and Oaks. The rocks are hung with Ferns and Harebells, and all sorts of sweet wood blossoms are found in their season nestling in the shade. The Walking Fern lingers in the little marshes at the base of the trap-rocks, and Arrow-heads abound. Here, too, flourishes the Cranberry, trailing its delicate vines over barren surfaces, and Grasses and wild plants clamber over the hills in profusion. A report by Mr. Conway Macmillan, State Botanist of Minnesota, states that if it had been the idea of the legislatures of the adjacent states to preserve a typical group of northern plants as a kind of natural botanic garden, they could scarcely have selected a more favorable locality than the region about the Dalles. Few southern varieties of trees have strayed into this region, but the Juniper, the Larch, the Spruce and the Canadian Yew abound, while some noble specimens of the White Pine survive the wholesale devastation by the lumbermen. A variety of the Club Moss is characteristic of the bare hills near Taylor's Falls, and Ferns flourish freely, among them the little Woodsia, the Rock Brake and the Bulb-bearing Fern, which tapestries the cool ravines with its feathery fronds. The wonderful Mosses and Lichens which play so important a part in the color-scheme of the Dalles have already been referred to, and among the former are seen the famous Reindeer Moss, more properly a

Lichen, and the Fountain Moss, found only in water, grows here to sometimes a foot in length. Liverworts, kindred to the Mosses, are also in profusion, and great carpets of them may be found on damp cliffs near the springs. About a thousand species of the higher groups of plants are established about the Dalles. Rock Cresses and the Jewel-weed are everywhere. The Ram's-head, Lady's-slipper and the tiny *Hydrocotyle* now and then appear. Anemones, Violets, Jack-in-the-pulpit and other northern flowers in spring, and Golden-rod and Asters in autumn make the woods and fields gay with blossom. Heaths, dwarf Cornels, Indian Pipes, the southern Pulses and Spurges also abound, and one interesting plant, the Prickly-pear Cactus, has strayed hither from the desert. In short, the Dalles are a natural wild garden full of interest.

The landscape beauty of this reservation is inexhaustible. From one high point on the Wisconsin side below the elbow in the Dalles is seen the little town of Taylor's Falls nestling by the river, and another distant town on the Minnesota side gleams white against the background of hills dark with evergreens. A slender steel bridge spans the winding river, and under it the water foams and swirls between the rocky banks crowned with Spruces and Firs. Other stretches of the stream are as still as a lake in whose quiet bosom the shores are reflected, and a floating canoe scarce leaves a ripple behind. In the rapids all is commotion. The drifting logs struggle in heaps; the vexed stream roars and leaps, white with foam, down the incline. Again you paddle through a narrow gorge, where strange forms rise like monuments before the wondering gaze. Marvels of color delight one. Nature has clothed the rocks with red and purple and green, festooned them with vines and starred them with tender flowers. On all this beauty stern rock faces look down like petrified Jötuns mourning over the destruction of their forest home. There is a mysterious and terrible attraction about the fathomless wells dug by the slow grinding of the glacier. The geological formation tells a tale of prehistoric convulsions, of strange upheavals, of a boiling caldron wherein boulders and pebbles whirled about, and are now found imbedded in the trap-rock like plums in a monster pudding, afar from the present bed of the stream.

Merely as an object-lesson of botanic and general scientific value the Dalles are well worth preserving, and their exquisite wild beauty will be more and more cherished as the region about becomes more settled. It is a source of gratification to all lovers of nature that public-spirited citizens enough were found in the two states to preserve this gem of natural scenery from destruction as an Interstate Park before the hand of the spoiler, with pick and axe, had converted its rare features into utilitarian dust and ashes.

Hingham, Mass.

Mary C. Robbins.

### Ecological Notes upon the White Pine.

THE ecology of the Pines, especially of the White Pine, *Pinus strobus*, has interested me for many years. I have seen the White Pine in about all the conditions to which it is subject in the region of the Great Lakes, the Saint Lawrence, the upper Mississippi and the northern reaches of the Alleghanies, which constitute its principal geographical range, and no tree growing within this climatic area adapts itself to a greater variety of soil conditions. The American Aspen, the White Elm, the Red Maple and the Red Cedar compare most favorably with it in this regard. Its most congenial soil is one containing a fair supply of sand and gravel or light loam, where it usually attains the largest size. It does not generally occupy the ground so exclusively as the Gray Pine, *P. Banksiana*, or the Red Pine, *P. resinosa*, or several of the southern Pines. The finest examples are isolated or in companies of a few in forests of deciduous trees. Here it becomes their competitor, and from its range and ability to hold its own, except against fire and the axe, I should

never suspect any lack of virility, as has sometimes been charged to it.

The extreme conditions of soil and moisture for the White Pine are reached in the sand dunes and the rocky ledge and the peaty swamp. In dune regions its chief hardwood competitors are Oaks, mostly the Black, Scarlet, White and Bur Oak. In damper areas among the dunes, where the mineral constituent of the soil is chiefly sand, but mixed with more organic matter than on the hills, its principal competitors are species of Poplar and Birch. The dunes by the Great Lakes are as typical as any. Those at the south end of Lake Michigan, with their network of railroads, afford as adverse conditions as can well be found. Scarcely a year passes during which some of the ground is not burned over, and the ranging of cattle increases these unfavorable conditions. But in many spots on the sand hills, especially on their slopes, the White Pine if removed springs up again, and groves are formed in which trees from one to three or four inches in diameter closely crowd each other. If these chance to be protected for a sufficient time they make a respectable growth of timber, the smaller and weaker trees dying out by natural process of thinning. There are also spots where the Pines, both the White and the Gray, have an advantage over the Oaks. They are too damp or wet for any but the White Oaks. They are in hollows among the sand hills or flatter reaches of ground which have been raised above the swampy level by the gradual accumulation of sand brought in by winds and rains and by the deposits of vegetable matter, and thus have assumed drier conditions. Here the main competitors are the American Aspen and the Paper Birch, or, perhaps, the White Cedar. Thickets of Pine spring up in such places from seedlings to trees from ten to twenty feet in height. The soil is peaty, or has too great a supply of organic matter to suit the Oaks. Even the Tamarack may accompany the Pines, and the prevailing undergrowth shows plants adapted to peaty formations. Beyond the dune region in the bordering drift-covered land small areas are found among the hardwoods, where the Beech and the Sugar Maple predominate, in which the White Pine occurs. They are hollows, where sphagnum Mosses, *Vaccinium* and Gold-thread reveal a peaty soil. The bottoms, once covered with water, have been partially filled by soil washed down from neighboring hills and by the decay of organic matter, but are still wet ground.

Two or three more stations may be specified which show the persistence of the White Pine under different conditions of soil and moisture, as in western New York, where land was taken up and settlements began about a century ago. A farm in this portion of the state, in the western part of what is known as the "Finger-lake" region, came into my possession a few years ago. I examined with interest the remnants of its forest-covering and that on adjoining farms. The soil conditions differ widely from any already described. Its prevailing character is argillaceous. Though the underlying rocks of slate are heavily covered with drift, they are cut into and exposed by streams which rush down the steep hillsides. The principal forest-trees of the uplands are the Chestnut, Sugar Maple, Shag-bark and Bitter-nut Hickories, and two or three kinds of Oaks. The trees were comparatively young, for nearly all the larger ones had been cut down and removed. One of the pieces of woodland on the farm was well stocked with White Pine. It was on the top of a ridge where some gravel or sand was mixed with the clay, but the soil was essentially argillaceous. This wood was a mixed growth of Pine, Chestnut, Hickory and Oak. Scarcely a Pine exceeded a foot in diameter, showing that it was of recent growth. In ravines upon the hill-slope, difficult of access, were older trees, two or three feet in diameter. These were growing in a soil almost purely clay from the decomposed underlying slates, whose harder parts, where exposed, showed that they were slightly arenaceous. But they formed a soil very slippery and unctuous to the touch when wet.

West of the Genesee River, and not many miles from this farm, other conditions of growth are found. Some are areas of limestone, with a thin covering of soil whose mineral ingredients are almost entirely derived from the underlying rocks. Silix is plentiful in the form of nodules of flint, the rock being the corniferous limestone of the New York system of geology. As the rocks decompose the nodules break up into flakes, and the soil is often so full of chert and bits of limestone as to resemble beds of crushed stone. Wheat and Red Clover have been the main crops where the more favorable portions of the land have been tilled. The trees are chiefly Oaks and Hickories interspersed with occasional clumps or trees of White Pine. Here the White Pine grows in a calcareous soil, siliceous matter being present from the decaying flint.

Close at hand is still another condition of growth. The streams which drain the slope of country to the south of this outcrop of limestone come down upon it. But it is so fissured or porous along certain lines of underlying gypsum that the smaller streams sink into the earth before reaching the farther edge of an escarpment, and the larger ones lose much of their volume or wholly disappear in the dry season. The water thus lost for a time bursts out again at the base of the escarpment in clear, cold springs. The streams they produce with the contiguous swampy land give rise to Cedar and Tamarack swamps; with the White Cedar and the Tamarack the White Pine is intermixed. The roots of trees in such situations are in contact with a soil more or less pervaded or even saturated with water, though the Pine in most cases affects the drier positions. The water, well charged with mineral matter, is also a cause of the production of drier conditions, for its lime carbonate is deposited in the swamps and marshes, where it is forming extensive beds of travertine which are gradually filling them up. The Pines in places may be seen growing on these beds of travertine, where they appear near the surface. Leaves of trees and of shrubs, aquatic plants and other organisms are imbedded and fossilized in it. They all help to form hummocks of limestone and produce more favorable states for the growth of certain kinds of vegetation, among which the White Pine has taken a place. But the soil is still very wet and prevailingly peaty.

These specific illustrations of conditions under which the White Pine grows could be repeated and extended in all essential particulars by cases taken throughout its range. Extreme cases, or those apparently the most unfavorable, have been chosen in order to show its power of adaptation. Its growth in rocky regions, either of sandstone or the crystalline rocks, as well as in sandy or gravelly areas, is most familiar; that upon the clay hills bordering the outlet of Canadice Lake is the most exceptional in my experience.

## Plant Notes.

### *Viburnum dentatum*.

"It is wonderful to see the fertility of your country in *Viburnums*."  
—Collinson and Bartram letters, 1765.

THE Arrow-wood, *Viburnum dentatum*, is the most conspicuous small-flowered member of its family, for, unlike the others of this group, it is not restricted to damp ground and shaded woodland belts, but grows equally well on dry banks and in open fields. The foliage is so clean and healthy-looking all summer long, with a striking red marginal coloration in autumn; the white cymes of blossoms are so showy, succeeded by almost equally showy blue berries, that one might reasonably suppose it a plant worthy of attention, but in central Pennsylvania all the specimens that have ever come under my observation have been in a wild state. Of course, this *Viburnum*, like our other native species, is beautiful anywhere, for, taken as a class, there are no handsomer shrubs in our forest glades. But it does seem almost unaccountable that shrubs adapted to every use and situa-

Fig. 1. Sprays of *Viburnum dentatum*. See page 332.

tion should have been so universally neglected by American planters.

There is some bond between the Arrow-wood and Kinnikinnik, *Cornus sericea*, which it might be well to remember in planting, for they seem to thrive together when at home, and I have never found the latter in dry ground, except in company with the Arrow-wood. Unlike the Kinnikinnik, also the other blue-berried Viburnums, the fruit of the Arrow-wood is not very attractive to birds. Old mountaineers have told me that the berries were never eaten, but there is every reason to think they are mistaken.

The specimen from which the illustration on page 333 was taken is not very large, being about seven feet high, but it grows in a swampy meadow remarkable for fine Viburnums, and especially for beautiful Black Haw-trees; but the whole place is doomed, as the lower end is already the dumping-ground of a rapidly growing city. It would be interesting to know in round numbers how many, or rather how few, persons know our native Viburnums. The interest in naturalizing native plants is not yet widespread, and this curious limitation in the planting of shrubbery seems to be due to mental and not financial reasons. The average city or suburban dweller feels that he has performed a noble act when one Hydrangea and two Carolina Poplars proclaim aloud his lack of individuality, while in the country the same process of mind results, perhaps, in a purple Althea and some Marigolds. The rural mind ought not to be held responsible for such manifestations of taste, for drudgery of the hardest kind soon kills the æsthetic instinct that almost every one possesses early in life. Country children are often marvels of observation, and, though slow to narrate, they are passionately fond of flowers. In some of the most primitive places the little children make wreaths the livelong day, and garlands often serve the purpose of all other toys. As they grow older the boys' power of observation takes a practical turn, while it is slowly crushed out of the girls, until a new love of the common and distorted replaces the earlier and better taste.

It is the dreadful monotony of country farm-life that retards all movements toward improving conditions, and so long as the great majority of countrywomen on farms spend their lives in depressing drudgery as they do, it is useless to look for any improvement of external conditions. Just so soon as they realize that a "wild" bush like the Arrow-wood is as worthy of preservation as a purple Althea or a mildewed Lilac there will be a great interest aroused that will tell in every village and country lane.

Harrisburg, Pa.

## Entomological.

### The Influence of Environment on the Life History of Insects.

IT is not so long since that it was assumed that the life history of an insect being once carefully made out, work with that species was done; and remedial measures once ascertained they need only be restated again and again until all were familiar with them. Acting upon this assumption, which at the time was entirely justified, station bulletins were printed all over the country repeating well-known life histories and well-known means of checking injury. So much of this was done that considerable adverse criticism was aroused, and when some of the entomologists attempted to verify old accepted knowledge, it was objected that there was an unnecessary and undesirable duplication of work. So matters remained for a time, until it was gradually forced upon the worker that his constituents made altogether too many failures to be satisfactory to him or to them. To prove his case he tried his own recommendations, where he had the necessary time and opportunity to do so, and in many instances failed as completely as did his farmer friends. Sometimes these failures

were made by men that had succeeded perfectly in earlier days, in other fields, and they repeated their experiments yet more carefully a second season before they would believe in their own results. Observations carried on during the course of the experiments also indicated an altogether unexpected amount of variation from the published histories of many species, and an astounding difference in the amount of resistance to poisons, either external or internal. It is hardly necessary to go into much detail here; but from all sides come accounts of varying and sometimes contradictory results, which seem to demonstrate the necessity of studying each destructive species of insect in each distinct environment.

The notes on the codling moth by Mr. Card, in the issue of GARDEN AND FOREST for August 4th, emphasize that point. Mr. Card refers to Professor Washburn's results in Oregon, but does not mention the more detailed observations of Mr. Slingerland in New York on the same subject. His own observations differ greatly in some respects from those made by the gentleman just cited, and they will not do at all for New Jersey. Observations made in Germany indicate a yet different habit from any observed here, and the situation in California will prove yet different.

Mr. Card places much stress, and rightly, on the fact that in Nebraska Apples blossom, set and even close the calyx cup before the moths appear or the eggs are laid. In New Jersey that is not so. It is almost impossible to find an unhatched pupa in the orchard after the blossoms begin to drop. In our state there is nothing but larvæ to be found in the cocoons until the first spell of warm weather that starts the sap in the trees and induces a swelling of the buds. Then, almost over night, everything enters the pupal stage, and this is usually short—much less than the duration of blooming-time in an Apple orchard. But even in New Jersey differences exist. Near New Brunswick there is positively a single annual brood only. South of Burlington County there is at least a partial second brood, and the practice that would prove perfectly satisfactory in one locality would be distinctly imperfect in the other. The truth is that insects, like all other creatures, adapt themselves to their surroundings, and that their habits and life histories are different in even slightly different localities. I have never seen the egg of a codling moth on a leaf, and I believe none has been previously recorded. Nevertheless, I do not for a moment discredit Mr. Card's observation.

We have a similar set of experiences with insecticides. Insects which succumb readily to kerosene in the Atlantic states defy it absolutely in Colorado, while we are just as likely to find the food-plant much more sensitive to it. Washes that easily destroy the San José scale in California are ridiculously ineffective in the Atlantic states. This very scale is changing its life history and habits in the east materially in several directions. I will venture the prediction that in half a dozen years it will not be considered a first-class pest in New Jersey, though I would not like to extend this prophecy to localities with which I am less familiar.

The point of all this is that we must begin afresh our studies on the life history of many of our common insects, with special reference to the locality where the study is made. There will be some duplication of labor, but the work will be comparatively easy because of what has been already accomplished. I am certain that in some cases our practice will be completely changed, and some confusing and distracting results will be satisfactorily explained.

It has been too much the practice, perhaps, to consider discrepancies between the results of recent and older observers as proof of the superior accuracy and reliability of the former, but it is worth while to inquire in all cases whether both have not been correct and whether the differences are not due to the varying conditions in the insects themselves and their surroundings.

New Brunswick, N. J.

### A Renewed Outbreak of the Asparagus Rust.

**E**ARLY this spring the appearance of this fungus was noted in GARDEN AND FOREST (see page 236), and since it is a new and alarming enemy, Dr. Halsted has sent out a fresh circular of warning. In a badly infested Asparagus field the plants generally appear as if they had matured unseasonably, and instead of their usually healthy color the field looks brown, as if frosts or insects had robbed the plants of their vitality. When viewed near at hand the diseased plants are seen to have the skin on the stems, large and small, blistered, and in the ruptures of the epidermis dark brown spots can be detected as shown in the figure below. These brown dots or lines are of various sizes and shapes, and remind the close observer of similar spots in the broken skin of stems of grains and grasses and of the leaves of corn, also due to rusts, but not the same kind as that of the Asparagus.

The Asparagus rust is due to a fungus, *Puccinia asparagi* DC., that is, a minute plant consisting of microscopic

Fig. 44—Portions of Rusted Asparagus Stems.

threads which grow through the substance of the Asparagus plant, taking up the nourishment that is needed, and finally break through the surface to bear the innumerable brown spores that give the dark color to the spots on the Asparagus stems. This is the last stage in the development of the rust fungus, and as such remains over the winter. When the warm, moist weather of spring and summer comes, the spores above mentioned germinate and a new lot of Asparagus plants may become infested.

There are two general methods of checking the rust, namely, by destroying the spores and by preventing their growing upon, and getting a foothold in, the substance of healthy Asparagus plants. The rust fungi are among the most difficult to check—by protecting the plants they feed upon—by means of fungicides, Bordeaux mixture, etc., sprayed upon them during the growing season. While something may be hoped for with the spraying pump, the chief method of eradication lies in the destruction of the many spores. This can be done in a very simple and effective manner by carefully gathering all the parts of the Asparagus plants that are above ground and burning them. It would be a waste of time to stack the tops and leave

them to natural decay; and to place them in manure-heaps would be still worse. The only safe thing to do when a serious enemy like this is in the Asparagus field is to burn the plants, even to the last scrap that can be gathered up. Let this be done at once, for any delay means the breaking up of the brittle, rusty plants, and a generous sowing of the spores upon the ground. If the fire could go over the whole field and burn all the small as well as the large pieces, this would be the best of all.

### The Hybrid Gladioli.

**S**UMMER-FLOWERING Gladioli are now at their best. Fine effects can be made by planting them in groups of one color or by arranging them in lines of separate colors, and their decorative value is thus enhanced. A mixed bed cannot be arranged so well, and the result is often an inharmonious medley. Again, mixed varieties, sold as unnamed seedlings, no matter how much inbred to conserve the type, still revert, and vary greatly in time of blooming.

The direct hybrids and inbred crosses from the first were superior to the types in beauty. The Gandavensis type or section is the oldest and best known. It originated half a century ago as a cross between *Gladiolus psittacinus* and *G. oppositifolius*. Their showy colors and the ease with which they are cultivated made them at once permanently popular. The Brenchleyensis, with scarlet flowers, is one of the best representatives of this type. All are characterized by erect, somewhat trumpet-shaped flowers and an upright and close arrangement on the spike. Professor Gibbs is a fine example. It is a handsome purplish pink with a white blotch, and originated from seed sent by Dr. Gibbs, of Newport, to Professor Sargent, of Brookline. Others are John Laing, deep red; Agathe, rose tinted with orange; Feu Follet, white, throat striped with red; Rayon d'Or, straw-colored, with red markings; Snow-white, an excellent variety for florists; Sultanæ, satiny rose. Probably a thousand varieties have received names, and a large number of these are in cultivation to day.

The finest colors among Gladioli occur in what is known as the Lemoinei section, and the form of flower is also distinct, with the hooded characteristics of one of its parents, *G. purpureo-auratus*, strongly marked. The strongly contrasted coloring, divided as if by lines, makes the most attractive feature. Rich red and yellow shades predominate, but there are frequent shadings of white and pink. The well-marked blotching readily calls to mind some of the fancy French show Pelargoniums. Some of the best are André Chenier, pink, with large satiny black blotch bordered with yellow; Mademoiselle Lemoine, straw-yellow, with purple blotches; Masque de Fer, bright red, lower segments deep maroon, with yellow centre, specially good; E. V. Hallock, sulphur-yellow, large crimson blotch, white centre and border of yellow.

The introduction of *Gladiolus Saundersii* about a dozen years ago brought to the notice of the hybridizer a new large-flowered species, with flat, orange-scarlet blooms and a conspicuous lower segment. *G. Saundersii* is hardier than many of the hybrids, and frequently has endured the winters here. Crossed with some of the harder species it has given us the Nanceianus section. This, as well as the Lemoinei group, is hardy in Europe, but the corms should be lifted here, though they occasionally stand through the winter. The Nanceianus group is characterized by large open flowers, and many are finely marked. Some of the best are Fred Bergemann, salmon-red; Canrobert, purplish marked, and striped with rose; Charles Baltet, rosy-violet, with white throat; G. Paul, velvety crimson, with yellow blotches.

Still another type has originated, known as the Childsi, which is from a cross between *Gladiolus Saundersii* and the Gandavensis hybrids. Thus far it is in the hands of the hybridist, but soon many varieties will be in cultivation.

Gladioli do best in a rich, well-drained soil, and should not be planted more than three inches deep. This has been a favorable season for these plants on light soils. They enjoy abundant moisture when growing. It is better to lift the corms before frost cuts them down, and store them in frames with a little sand or soil over the roots, and they thus ripen gradually and thoroughly and the food stored in the stems and leaves returns to the bulb. Bulblets form about the base of the old bulbs, and when a variety is extra fine it should be marked so that these can be taken care of at lifting time. If planted separately the following spring they will make fair corms the same season. Gladioli are easily raised from seed, with even less trouble than onions. Large numbers of

unnamed seedlings are each year put on the market. This would be well enough if the raisers would take the trouble to flower them and cast aside the worthless varieties. Although some of the finest varieties have come from random crosses, yet comparison with carefully fertilized seed will show a marked difference in the seedlings. There is no doubt that Gladioli and many other summer-flowering roots are much injured in the seed stores by being kept in hot, dry rooms, and they should be stored in a cool place, for much vitality is lost when they are forced into growth before being planted. Early planting is best. If put into the ground in April they will make good roots and not be above the soil before danger of frost is past.

Wellesley, Mass.

T. D. Hatfield.

### Sparaxis pulcherrima.

A CERTAIN gentleman always asks me when we meet what I have that is new, meaning in the horticultural line. The next time I shall answer, with much pride, that *Sparaxis* (*Dierama*) *pulcherrima* has kindly blossomed in my garden. I feel much pleased, for I have never seen it elsewhere, and several experts of my acquaintance have given it up as an intractable subject. The only secret, I fancy, is to wait for the flowers until the plant is strong enough to produce them, and the treatment I have given has been of the simplest kind. I raised the plant from seed about six years ago and kept it for two years in a pot, but, finding the growth slow and unsatisfactory, I turned it out into the open ground near my *Ixia*-beds, and there it has been ever since. Its foliage remains fresh and green until the end of November, when I cut it off near the ground and cover the roots with four inches of Pine-leaves. In the spring the new shoots appear about two weeks later than the *Ixias*, a tardiness which once caused me to report in this paper that the winter had killed it.

The narrow foliage, in appearance much like a *Sedge*, attains a height of about two feet. The flower-stalks would be five feet high if they stood erect, but the weight of the flowers causes them to arch over in a graceful curve. Besides the chief cluster at the ends of the stalks, which open first, there are numerous spikelets, each with from five to eight flowers of the same bright violet-crimson color hanging at regular intervals. As the terminal blossoms drop, the stalk assumes a semi-erect position, which, of course, causes the spikelets to arch during their time of blooming, and, as the seeds in the terminal capsules become large and heavy, the main stalk is again brought down in an arch. The swaying of the stalks with every breeze adds much to the attractiveness of the plant.

Canton, Mass.

W. E. Endicott.

### Some August Flowers.

*ASCLEPIAS INCARNATA*, a native Milkweed, with light pink flowers, makes a good display when grown in a garden. It is somewhat umbrella-like in form, the top covered with flowers, and these are borne for about six weeks during July and August. In damp places, near creeks, where it is often found, it is not uncommon to find plants with flowers almost white.

*Dicentra eximia* is one of the most constant blooming of herbaceous plants, and is in flower from early summer until late in autumn. The flowers are purplish rose, not a striking color, but its ever-blooming character is a great point in its favor. In the same list may be placed *Callirrhoe involucrata*, with bright rose-colored flowers, and *Origanum vulgare*, rosy purple. Both of these plants are constantly in bloom. The *Callirrhoe* is an almost prostrate plant, while *Origanum* reaches a height of two to three feet.

*Daphne cneorum*, whose sweet-scented flowers are so numerous produced in early spring, is abundantly full of blossoms now. In fact, it is rarely without flowers at any time during the season, and they become more abundant in late autumn. It delights in a rich, sandy soil.

Germantown, Pa.

Joseph Meehan.

*Heliopsis Pitcheriana*.—This plant, of which the English garden papers speak highly, is plainly but a selected form of *Heliopsis laevis*, as self-sown seedlings at once revert. For years it has been one of our worst weeds. It is hard to kill, crowds and robs other plants to their exclusion, and is fit only for the roadside. As a decorative plant it is not nearly as handsome as our common *Rudbeckia hirta* or *Coreopsis lanceolata*, which here has strayed from the borders and keeps it company.

## Correspondence.

### Arsenate of Lead with Bordeaux Mixture.

To the Editor of GARDEN AND FOREST:

Sir,—I was somewhat surprised this year in making a test of a combined fungicide and insecticide—arsenate of lead and Bordeaux mixture—to find that both foliage and fruit of Crab-trees, to which it was applied, were seriously injured.

I used four pounds each of copper sulphate and lime to each forty-five gallons of water, and to this added four ounces of arsenate of lead. Three applications were made. The amount of injury increased with each application from "slight," "considerable" to "severe," and consisted of a burning of the foliage; a rusting and scarring of the fruit. Arsenate of lead and Bordeaux mixture applied separately to adjoining trees produced no injurious effects. I should like to know if similar results have been noted by other experimenters.

Central Experimental Farm, Ottawa, Canada.

John Craig.

### The Codling Moth.

To the Editor of GARDEN AND FOREST:

Sir,—Professor Card's article on this subject in your issue of August 4th is a most timely and valuable one. This year, in the Mesilla Valley, New Mexico, I have been trying various measures for the destruction of the codling moth, after becoming convinced that mere spraying, as ordinarily recommended, was of very little avail. The rate of increase in this warm climate is prodigious. The moths from over-wintered larvæ emerge with us as early as April 24th. The second generation of moths, or rather the moths of the first lot of 1897 larvæ, appeared at the end of June. By the end of July another cycle was completed, and for the third time moths were on the wing. The young larvæ of the third generation of this summer are now (August 9th) in the apples.

At the end of March we had the test orchard well searched for hibernating worms. Great numbers were found under loose bark, but the places where they most congregated were cracks in dead wood or old stumps. All such cracks should certainly be stopped up with wax. The worms were destroyed to a considerable extent during the winter by woodpeckers, and a *Clerid* larva also devoured them. We found many more worms in the apple cellar belonging to the orchard than on the trees; such places should always be searched. Toward the end of May the wormy apples were picked off the trees, as far as they could be found, and destroyed. About 14,000 wormy apples were found on 650 trees. The apple crop was a large one, and the injury done by the first brood was not of the slightest consequence. On June 2d, when the picking was finished, it was found that the part of the orchard which had been sprayed was about as wormy as the rest.

By banding the trees we have caught great numbers of the worms, but they are gaining on us, nevertheless. It will not be possible to estimate the results of the work done until the end of the season, but the outlook is certainly discouraging. I find no hymenopterous parasites of the worms here, though some die from the attacks of the fungus *Sporotrichum*, especially in confinement. Certain orchards which had no apple crop last year, owing to late frosts, show this year comparatively few worms, even when no measures have been taken to prevent the attack. We seem to have obtained good evidence that the moths do not ordinarily fly any great distance, but lay their eggs on or near the trees on which they breed.

Mesilla, N. M.

T. D. A. Cockerell.

### The Elm-leaf Beetle.

To the Editor of GARDEN AND FOREST:

Sir,—Referring to the communication by Professor Britton in last week's issue of GARDEN AND FOREST, if spraying is thoroughly well done, a season can be occasionally passed, provided there are not too many sources of infestation in the immediate vicinity. Nevertheless, trees will be considerably injured by omitting even a single year's work under ordinary circumstances, as the state of affairs in New Brunswick during the present season will illustrate.

During the early part of 1896, Elm-leaf beetles were excessively abundant, and a large proportion of the trees in the city were defoliated. Considerable spraying was done by the City Improvement Society, and trees treated under their direction were generally in fairly good condition. The trees on the College Campus were treated, as usual, with arsenate of lead, and remained in good condition throughout the season. During the early part of July, when the larvæ were about full

grown and ready to pupate, a period of peculiar weather favored a disease which attacked the larvæ and pupæ to such an extent that only scattering beetles here and there escaped. It was a true epidemic disease, and so fatal that it was almost impossible to get together a small collection of adult beetles for which I was asked by a correspondent. Very few beetles were seen during the winter in their ordinary hiding-places, and the janitors of the College buildings informed me this spring that where they had been in the habit of sweeping up quarts in previous years, they then saw only an isolated beetle here and there. So few beetles were seen early in the spring that I decided to omit the first spraying of the trees on the College Campus, and so few eggs were laid that, as an experiment, I decided to omit spraying altogether. When the larvæ hatched, however, it was seen that there were a great many more insects than had been counted upon. The trees on the Campus remained in fairly good condition, although some branches here and there showed a considerable proportion of eaten leaves; but in other parts of the city European Elms showed just as much injury as they had manifested during previous years. Under ordinary conditions, thorough spraying will kill a very large percentage of the insects that would otherwise come to maturity; but even under the best treatment a small percentage will survive, and that percentage will be sufficient to stock the trees during the season following. We have only one brood of the insects in New Brunswick, and in times past we have not found two annual sprayings any too much to keep the insects in check on the trees surrounding our institution.

I consider it a poor plan to adopt the suggestion that only one-half the trees in a city be sprayed each year; but on the other hand, I think that if one part of the city was thoroughly sprayed twice one year it could be protected by a single spraying the second year. The recommendation is always to make a spraying when the adults appear, so as to prevent them from laying eggs as far as possible. The second spraying should be made when the eggs are all hatched, to kill the larvæ and prevent their development to beetles. If that be done thoroughly one year it would be necessary the year following to make only the second spraying to kill off the larvæ. In a season like the one through which we are now passing, the Elm-trees support insect injury very well, because there is an abundance of moisture to enable them to repair damages. I fully expect that spraying will have to be thoroughly done on the trees near our buildings next season, because there have been many more beetles developed this year than were permitted to come to maturity for several years past, when active measures were taken.

Rutgers College, New Brunswick, N. J.

### Critical Notes on the Loganberry.

To the Editor of GARDEN AND FOREST:

Sir,—It has been a good season to discover imperfections in this new fruit as grown here in the east, and we have a short list of them to record. It is possible that some of these may be false accusations, and that when we understand the peculiarities of the plant better we shall know that they are the result of improper treatment, rather than natural traits, but for the present it is only fair that they should be noted as faithfully and given as much publicity as the good qualities that were observed last year.

First, all of the canes that were not covered last winter winter-killed nearly to the ground.

Second, the canes that were covered with earth about the middle of January were apparently injured considerably before that time, but the plants that were covered about the 20th of November wintered admirably.

Third, even where the canes were not injured, the fruit did not mature well this year. There was every indication that the few plants that we had would yield a large crop of excellent quality, until about the middle of June, or when the earliest berries began to turn red; then it was noticed that the leaves on the fruiting canes were blighting, and later this developed into a blast that extended to the berries, and they began to show brown spots, which, upon examination, proved to be where the pulp had dried down upon small groups of seeds, and usually it was the seeds near the hull at the base of the berries that were affected. This trouble was attributed to the excessively wet weather, and this theory is supported by the fact that Black Cap and other early Raspberries appeared to suffer severely from the same cause, although they showed the effects differently.

Fourth, some of the Loganberry-plants seem to be either diseased or to lack constitutional vigor. The leaves of such plants are small and light-colored and the growth puny, while

other plants growing beside them are exceedingly vigorous. We have noticed these plants in every lot of the Loganberry planted, and have not been able to find a satisfactory reason for their condition. So far as observed by us, such plants never amount to anything.

The young plants propagated from hard-wood cuttings last winter have exceeded our expectation in vigor of growth. Already they have outgrown the seedlings of the same age, and are hard in pursuit of the stolons that started into growth much more freely than they did in the spring.

We still are inclined to believe that the Loganberry may be profitably grown for market in New England, at least in small quantities, although we are free to confess that we are disappointed in the behavior of the plants here this season.

Rhode Island Agricultural Experiment Station.

L. F. Kinney.

### Electricity in Vegetation.

To the Editor of GARDEN AND FOREST:

Sir,—There is little doubt that nature makes an important use of electricity in the growth of vegetation, the blossoming of flowers and the ripening of fruits. The method of electric appropriation and action is as yet not fully understood, but the secret will be revealed to man during the coming years. Just as science is proving that the nerves of the human body show polarity under the action of electric currents, so it is shown that there are currents of electricity in all parts of vegetables except those which are insulated with dry bark, etc. In flowers the currents are more feeble, but in the succulent fruits and certain cereals they are of considerable strength, depending upon the season, being greatest in spring-time when the plant is rich in sap.

Atmospheric magnetism is seen in tree-growth. Branches on the edges of groves are drawn outward by the electrical attraction of a highly oxygenated atmosphere and that of the unshaded earth. Artificially electrified soil increases plant-growth, as every one is aware. Some curious experiments have already been made in electrical-plant culture, and results have been obtained which warrant their continuation, although they have not yet reached that point of permanent scientific development which insures a fruitful transformation of fields and market-gardens by means of artificial electrical stimulus.

It has long been known that fruits exhibit electrical conditions, and that in puncturing them at their electrical poles and closing the circuit, it has been possible, by means of special mechanism, to study the magnetic variation. The ascending sap of trees and the cortical sap (which, as is well known, have not the same chemical composition) react upon each other, giving marked electrical phenomena. From the pith to the cambium the envelopes are electrically less and less positive; from the cambium to the epidermis they are more and more so.

What is to be the future of patient experimentation along these lines? Already in hot-houses fruits are forced by strong electric illumination. Possibly by reinforcing this external action with the passage of an electric current in soils charged with chemical products marvelous results shall be obtained—fruits and flowers magically improvised, forests created as by a fairy wand out of denuded deserts. Such improvisation has nothing improbable about it in view of the experiments which have already shown the mysterious and powerful influence exerted by electricity and magnetic currents upon vegetable life.

[A pleasing speculation—but prophecy is quite unsafe.—ED.]

### Recent Publications.

*An Illustrated Flora of the Northern United States, Canada, etc.* By Nathaniel Lord Britton and Hon. Addison Brown. Vol. II. New York, 1897.

The second volume of this notable work completes the Choripetalæ and includes the Gamopetalæ through Menyanthaceæ. The success which it has attained justifies the wisdom of the great undertaking. As an exposition of views that are undoubtedly gaining ground it must needs take a peculiar place in the future study of the flora with which it deals. Whether these views will meet with general acceptance in their entirety or not, it is an advantage to have them so ably presented. If the analytic as opposed to the synthetic method of treatment of plant forms seems sometimes carried to the extreme, we cannot close our

eyes to the fact that such tendency is encouraged by the recent increase of active field study, the lack of which in the past has undoubtedly left regrettable marks on our botanical literature. Though the general outlines of the flora of a new country must necessarily be drawn from closet study, the details cannot safely be left to that alone, and the success achieved by some of the newer hands in the elaboration of our eastern flora, largely due to careful field investigation, should be gratefully acknowledged. Some of the best results of such study find place here for the first time in a general work.

We again express our pleasure at seeing our plants arranged in a sequence so much preferable to the accustomed one, and their descriptions accompanied throughout by figures. Some of the latter leave much to be desired, but most of them are fairly excellent and must be of great service to those for whom they are intended—that is, the unprofessional students who need confirmation of their determinations made from descriptions. It is not fair to expect elaborate illustrations under the limitations enforced by the plan of this work or that the specialist should always find them adequate.

### Notes.

We recently received some specimens of the new black cherry, the Dikeman, from Mr. S. D. Willard, of Geneva, New York. The fruit was picked on August 16th and was in excellent condition when it reached us, nearly a week later. It is of good size, remarkably firm and very sweet; indeed, it would be better with a little touch of acid. It is certainly the finest cherry we know which ripens so late.

The Black Locust is a common tree in West Virginia, where it is found in groves of considerable extent and is of great commercial value on land that has been allowed to revert to forest after having been used for agricultural purposes. In the late annual report of the West Virginia Experiment Station, Professor Corbett says that it is considered of greater value than any native wood for use as driving blocks in sinking points for driven wells. The timber closely approaches in value that of Red Cedar for posts, and this, together with its rapid reproduction, constitutes its greatest value, although it is much sought for by the manufacturers of hubs for carriage wheels and for other uses where great resistance to pressure is required. The largest Black Locust in West Virginia stands near the entrance of an abandoned coal mine, not far from Morgantown. It is a remarkable tree, being fully four feet in trunk diameter and at least one hundred feet tall.

The section of Florida adapted to the open-air cultivation of the Pineapple on the east coast and in the middle of the peninsula is mostly on ground that northern farmers would consider barren sand dunes. Nevertheless, there is much good plant-food in the soil, and good Pineapple land near West Palm Beach, for example, costs from \$150 to \$250 an acre. Plants of the red Spanish variety cost something like \$4.00 a thousand, and from eight thousand to ten thousand can be grown on an acre. It is found advisable to set them close together so as to suppress weeds and prop up each other's fruits, for if set wider apart the fruits are inclined to grow large, topple over and become sunburned on one side. A correspondent of *The Country Gentleman* states that good suckers will fruit in twelve months after setting. Plants set in August or September will give a good half crop the following May and June. The open-air pineries of the Indian River do not, as a rule, produce more than a hundred standard eighty-pound crates to the acre, but they will keep this up from three to six years without renewing. If the grower nets from \$1.50 to \$1.75 a crate he is doing well. Of course, this is no price for fancy pineapples under glass.

Within the past fortnight 207 carloads of California pears, peaches and plums, with a few grapes and nectarines, have been sold in this city. And, of course, this large quantity is only supplementary to supplies of the same kinds of fruits from eastern, southern and middle western states. On Monday of last week, for example, thirty-three carloads of California fruit were sold, the largest amount ever disposed of here in one day. During the same week peaches from eleven other states formed part of our supply, so that it is not surprising that very low prices were the rule for the showy but less luscious California peaches. The best freestones from the Pacific coast have been selling here for seventy cents a box,

while many have brought but forty-five cents, and, contrary to general experience, clingstone peaches, because of their large size and showy color, commanded higher prices. Seckel pears were a small part of these shipments, along with the handsomest Bartletts ever offered in our markets, and as much might be said for the plums now in season.

According to a correspondent of the *Evening Post* the army of pickers that descends upon the Cranberry bogs of Wisconsin every autumn is composed chiefly of Poles, Indians and half-breeds, the Indians being considered the best pickers because they never strike and always accept the prices offered by the overseers. As a rule they earn a dollar a day and their board. They bring their lodges and tepees with them and camp on the field. The Indians will not begin to work until half-past nine in the forenoon and they promptly knock off at four in the afternoon, in spite of persuasions or threats. This peculiarity sometimes proves costly to the growers, for if a killing frost is threatened in the night the owners are compelled to hurry about and hire more white pickers, since it is a waste of time to try to get an extra hour's work out of an Indian. He would see the whole field frozen stiff first. At such times the Poles realize the advantage of the situation and demand extra wages for overwork. The Indians are good weather prophets and serve a useful purpose in foretelling when to prepare for frost, and when the word issues from the lodge of a chief that frost is approaching the bogs are immediately flooded and extra help is employed. If the water covers all the berries in time no damage happens, but those that are left exposed will be ruined.

Some investigations by Mr. A. F. Woods, of the Division of Vegetable Pathology in the Department of Agriculture, seem to indicate that the so-called "bacteriosis" of Carnations, first described by Dr. Arthur in 1889, is not due to bacteria, but is a direct result of injuries to the plant by thrips or aphides. In a paper read at the recent meeting of the American Association for the Advancement of Science, Mr. Woods brought out the fact that neither fungi nor bacteria are present in the earlier stages of the disease, and that their presence is not constant as the disease advances. A disease with all the characteristics of this bacteriosis, excepting the presence of bacteria, can be produced by aphides, and since the injuries in their earlier stages are not accompanied by bacteria, the aphides cannot be charged with carrying any infectious germ. The Carnation is readily influenced by extraneous conditions, and the reaction to the injuries of aphides and thrips vary largely, and plants carelessly grown suffer more seriously from punctures by the aphids than vigorous plants do. The sum of the matter is that the greatest care should be used in selecting and propagating stock, in furnishing conditions for vigorous growth and in keeping down aphides and thrips. It is these insects, and not bacteria, with which the practical grower must contend. Of course, good stock and good conditions of growth can never be neglected, and Mr. Woods' investigations give emphasis to what growers already know—that the disease is often the result of neglect, and that the way to have healthy plants is to give the closest attention to every detail of culture.

Many Orchids which grow and flower luxuriantly for some time after their importation gradually fall away and ultimately die. Various theories for this degeneration have been put forward, but the puzzle remained unsolved until now, when some experiments in France, reported in a recent number of *The Orchid Review*, seem to give a satisfactory explanation. Flowering is an exhaustive process, and investigations were made with *Cattleya labiata*, which produces many flowers and is grown in a mixture of Fern fibre and sphagnum, which contain little nutriment. The *Cattleya* was analyzed chemically in 1891 when it was imported, and a similar analysis was made of plants in 1897 after six years of cultivation. The results given in comparative tables show that the latter plants contained less dry material, less organic matter, potash, lime, magnesia, phosphoric acid and nitrogen, while water, sulphuric acid and two or three other substances, which were only present as traces in the imported plants, have increased. This analysis seems to show that the degeneration is attributable to exhaustion caused by the production of flowers without any means taken to compensate the plants for loss. The conclusion arrived at is that in order to counteract this exhaustion, *Cattleyas*, at least, should receive a mixture of suitable fertilizers containing nitrogen, phosphoric acid, potash, lime and magnesia. All this means that Orchids are subject to the same laws as other plants; that we cannot go on cropping without supplying food. But just here the question to the practical Orchid-grower comes, How shall these elements be most successfully applied?

## Harmony in Small Country Places.

IN planting the ornamental grounds of a small country place a wise choice of material is just as important as a wise decision with regard to the needed amount of foliage and its proper distribution. Of course, almost all of Nature's products are beautiful when considered in themselves; but now that the resources of all climes and countries are at the planter's command, he may so combine and contrast beautiful plants that their collective effect will be displeasing.

The most important quality to obtain in ornamental grounds is unity—harmony of general effect. And, in one sense, it is very hard to obtain, for it means much self-denial. Horticultural interest develops with its exercise. Year by year the planter is tempted to introduce more and more kinds of plants within his gates, as his knowledge of their variety and his appreciation of their different kinds of beauty develop. If his place is very large he may somewhere find a good chance to indulge all his likings. But on a small place formal avenues and graceful groves and clumps of trees of many sorts, peaceful lawns and varied shrubberies, orchards, flower-borders, rose gardens, pineries, arrays of native flowering-plants, and collections of showy exotics cannot all be secured without detriment to the effect of each group and fatal injury to the effect of the place as a whole. Many things in themselves desirable must sternly be refused admittance if the most desirable of all possible things—restful harmony in the general result—is to be achieved.

Given a small place, the best course for the owner to pursue is, first, to decide whether he has so strong a desire for a collection of any special sort that he positively cannot do without it. If he decides that he has, he should reserve for it the spot where it will interfere least with the effect of the rest of his grounds. And then he should sacrifice his desire for collections and specimens of other sorts and simply endeavor to make the remainder of his grounds beautiful.

In prosecuting this aim the best test will be the question: Will the result please the eye of a cultivated person who is not a horticulturist? Will it, for example, please the eye

of an artist? This is the only right result to secure in the grounds immediately about a dwelling-house. If they are given up to the indulgence of special horticultural tastes they may prove very interesting to examine, but they will not be beautiful as a picture. And the environment of a home should always be a charming picture of one sort or another.

If this truth has been accepted, and if, as was indicated in a former article, the owner has decided where his thicker plantations shall be made, and where his more isolated trees and shrubs shall be set, still he is not ready to begin actual work. He must decide what kinds of trees and shrubs and flowering plants he will use to produce his artistic little landscape. If any conspicuous plants of Nature's growing already occupy his ground, the proper character of his scheme is indicated thereby. Nothing should be introduced which is out of harmony with them, and the most harmonious things are likely to be those which Nature has associated with them in this same part of the world. No rule, however, is more generally ignored than this. The more definitely Nature has laid down the path which the planter should follow, the more likely he is to wish to escape from it. If his grounds are altogether bare, he may be satisfied to set out native Maples, Elms, Pines or Hickories. But if some of these already grow inside his fences he is pretty sure to seek the nurseryman and inquire what he can offer that will add "variety" to his place. Thus we may discover the genesis of those unfortunate agglomerations of inharmonious trees, shrubs and flowering plants which so often distress the careful observer of American country places. Monotony has been feared; variety has been desired; an inartistic medley is the result; and very often it is of a glaring kind, including profuse displays of plants which bear foliage of some abnormal hue, red or yellow or purple, bluish or whitish, blotched or streaked, or which grow in abnormal forms, weeping or pyramidal, prostrate or umbrella-shaped. Even a single plant of any such sort should not be introduced into our plantations without great care. But if many are employed the effect cannot be good, no matter how much care is taken. Simplicity, restfulness, naturalness, harmony—these are the great requirements, and all of them are sacrificed when many eccentric, abnormal, or even very showy plants are introduced. Many a small place which has been filled with these at great expense is an offense to the eye of the artist, and all the more so if dignified trees or beautiful shrubs of native growth raise their heads amid the medley. And, moreover, real variety is not thus achieved. While each place is a medley in itself, each one resembles its neighbor, for the owners of all have been guided by the same mistaken ideas and followed the same mistaken path.

Variety is indeed desirable in our pleasure-grounds. They should not be individually monotonous; they should not all resemble each other, and they should not look like bits reserved from pre-existent meadows or cut out of pre-existent forests, no matter how beautiful these meadows and forests may have been; they should all reveal the touch of art, and each of them should have its individual, personal charm. Nevertheless, a study of the native forest and the neighboring meadow, brookside and glen will afford the best possible patterns for the effective and varied as well as for the harmonious planting of our pleasure-grounds.

Among the hills and valleys and higher mountains of northern New Jersey and southern New York, for instance, many colonies of summer residences have been established in recent years, many fine large country places have been laid out, and the suburbs of many towns show streets of pretty cottages or expensive villas. Nowhere has Nature been more lavish with the beauty or with the variety of her gifts than in these regions; yet nowhere can more pitiful, or pitifully costly, mistakes in the way of planting be discovered. Hundreds of villa grounds and small places may be examined, and very few be found which are not deformed by a profusion of eccentric exotics or garden varie-

ties, and scarcely one in which an intelligent attempt has been made to secure variety in the right way. When the plantations are not varied in the wrong way—in the heterogeneous way—they are monotonous and uninteresting. Yet every acre of the "unimproved" countryside is filled with suggestions how to secure variety in the right way—in the harmonious way.

We have in mind, for example, a certain thickly wooded region where many summer homes have been recently established. Its forests are diversified as only American forests can be. But their predominant trees are Maples, Hickories, Chestnuts, Beeches, Hemlocks and Oaks of several kinds. In consequence, where the native growth has not been obliterated in the neighborhood of a house, these are the trees which most often have been preserved. Naturally, a certain monotony of effect would ensue without further planting; and, therefore, almost every owner has sought to relieve it by introducing striking exotics and abnormal garden varieties of trees and shrubs. If the intending planter would study the borders of the neighboring forest it would supply him with variety enough. Here and there he would find the Yellow Birch, with its beautiful bark and delicate leafage; the Tupelo, with its dark and shining leaves and picturesque habit; the Dogwood, with its unrivaled sheets of blossom; the magnificent Tulip-tree and dignified Basswood; the Red Cherry, with its burden of gleaming fruit; the Hop Hornbeam, with its pale green tassels of seed; the Sassafras, with its leaves of peculiar shape and varied tones of green, and the White Pine, so softly symmetrical in youth, so splendidly picturesque in age. These are the secondary trees of the forest in this particular region. None of them is able to reach its most beautiful development beneath the denser shade and amid the stronger arms of its more prominent associates. But any one of them, if planted where it would have room to spread and preen itself in the wind and the sunshine, would be much more ornamental than the Swiss and Austrian Pines, the Colorado Spruces, the European Maples, the Copper or Weeping Beeches, the cut-leaved Birches, the sickly-looking striped Negundos, the piebald Retinosporas, the golden Elders, or the stiff Altheas which have been profusely planted in their stead in the pleasure-grounds of the neighborhood. And, of course, the general effect of a place adorned with them as companions for the larger trees of native growth would present an harmonious effect which is now the very rarest merit that characterizes a small American country place.

#### William L. Bradley.

THE recent gift of twenty thousand dollars to Harvard College by Miss Abby A. Bradley in honor of her father was briefly noted in these columns a few weeks ago, when it was stated that the income of this endowment, to be known as the William L. Bradley Fund, is to be expended by the Director of the Arnold Arboretum to advance the scientific knowledge of trees. At the request of President Eliot, of Harvard, a sketch of the life of this energetic man was prepared by Miss Bradley, and as showing something of his enthusiasm for the subject which the fund commemorates, we publish the sketch now, with Miss Bradley's permission:

William L. Bradley, late of Hingham, Massachusetts, was born in Cheshire, Connecticut, May 25th, 1826. His father, Levi Bradley, was a prosperous farmer of Cheshire, and the son lived on the farm until the age of thirteen, when he entered mercantile life.

An unusual interest in agricultural pursuits determined his career. His attention having been attracted by certain discoveries in Germany of a method for producing chemical fertilizers, he decided in 1860 to embark in this new and undeveloped enterprise. Many years were spent in laborious research in the laboratory and in experiments in the factory and field before the business was profitably established. But by force of high character, an indomitable will and great business sagacity, in face of obstacles which would have daunted

a nature less resolute and far-seeing, he successfully founded the manufacture of chemical fertilizers in this country, and built up a business which during his lifetime became the largest of its kind in the world. He was also one of the first to enter the phosphate mining industry. In the early days of the first mining in South Carolina, and later in the more recent discoveries in Florida, he was one of the largest investors and one of the most progressive operators.

With a decided natural taste for the cultivation and improvement of the soil, he had also a great love of the beautiful in nature, with an especial fondness for trees. As a boy on his father's farm he spent much time alone in the woods and studied their various forms and habits. There was no tree or wayside shrub of that neighborhood which he did not know.

At the age of twenty-five he was able to own a large tract of land in Meriden, Connecticut, where he then lived. This land he improved extensively, draining, laying out roads, planting trees and carefully guarding the woodland. The possession and improvement of land, as years went on, became the recreation and passion of his life. He owned large tracts in nearly every Atlantic state from Maine to Florida. Among other farms, he owned a half interest in Montpelier, President Madison's beautiful estate in Virginia. The old manor house was repaired and made habitable and the exhausted land was brought into a high state of cultivation.

But it was during the later years of his life, at Hingham, when he had partially laid aside the cares of his great business, that he chiefly indulged his taste for planting trees, laying out roads and for the various occupations of landscape-gardening. Trees were planted along the roadside bordering his estate and thousands on the open lands. A large nursery of evergreen and deciduous trees was established. The wooded land on this estate was his especial delight, and many precautions were taken to guard it from fire or injury. Any particularly fine tree was brought into relief and given every opportunity to develop, while the shrubs were carefully preserved, and hundreds of native growth were transplanted. He entered into this congenial pursuit with the same energy and enthusiasm, and with the same breadth of spirit, that distinguished his business career.

It was here amid the work he loved so well, and with many plans for further improvement still unmaturing, that he was stricken with his last illness, and died December 15th, 1894.

#### The New View of the Hortulana Plums.

WHEN in 1892 Professor Bailey proposed the species *Prunus hortulana* to include the Wild Goose Plum and its nearest relatives, it was at first a relief and afterward a puzzle to horticulturists. It was a relief to have these anomalous forms separated from *Prunus Americana* and from *P. angustifolia* where they had previously caused confusion; and it was gratifying to have them separately characterized, even though it was very difficult to make the specific description fit all the varieties. But to maintain a description for the species which would fit all the varieties has been an ever-growing puzzle. And thus a second time Professor Bailey has brought us relief by his decision\* that this is "a mongrel type of Plums, . . . no doubt, hybrids" of *Prunus Americana* and *P. angustifolia*.

This new view of the Hortulana Plums seems likely to find much readier currency among pomologists than did the distinct species view. Indeed, some reputable horticulturists have never accepted the separate species notion; and no two anywhere or at any time have fully agreed upon the varieties which were to be referred to the species.

These cultivated varieties present an inextricable confusion of closely graded differences of character passing without a break from *Prunus Americana*, through the Miner group (Bailey's *P. hortulana*, var. *Mineri*), then through the Wild Goose group, and by way of such varieties as Schley, Clifford and Macedonia into the true Chicasaws. There is absolutely no line of demarcation, however dim, among these varieties. Such a series of forms cannot be conveniently doled out into species, even when we take the most advanced evolutionary view of what constitutes a species. But as soon as the Wild Goose group is understood to be a company of hybrids the matter becomes

\*L. H. Bailey, *Cornell Exp. Sta. Bull.*, 131, p. 170, March, 1897. See also *Bot. Gaz.*, Dec., 1896, p. 461.

comparatively clear. We can easily believe that there have been numerous independent hybrid origins followed by still more numerous secondary, tertiary and quaternary crosses, and these would account fully for the extraordinary variability and wide diversity of characters among these Plums. The varieties of the Miner group may reasonably be supposed to be secondary hybrids between Wild Goose types and *Prunus Americana*; or they may be, in some instances, primary hybrids in which the *Americana* influence has preponderated. Such varieties as Ohio Prolific, Schley, Texas Belle and Wooten may be supposed, on the other hand, to be secondary hybrids between Wild Goose and the Chicasaws.

All this will drive every Plum student, pomologist or botanist to a conclusion which we ought to have reached independently before, namely, that no full classification of our cultivated varieties can be made which shall be satisfactory to everybody. It is a matter of unquestionable convenience to divide our multiform varieties into several groups, but the lines between these groups are purely imaginary and arbitrary, and certain varieties which come near the division-line somewhere may be put into one group by one man and into the other group by another, and both men be right. It is all a matter of judgment, and a very delicate matter, too. There has already been too much controversy over some of these doubtful varieties. What plum students need now is less controversy and more patience.

The cultivated Hortulana Plums may be best understood by arranging them in four groups. Three of these have been mentioned—the Miner group, the Wild Goose group and the Schley or Clifford group. These form an unbroken series from *Prunus Americana* to *P. angustifolia*. There is a fourth group at present classified with the Hortulanas, but comparatively distinct from the others. This group is made up of such varieties as Wayland, Moreman, Golden Beauty, Reed, Leptune, Kanawha and others. I may be able to add a word concerning this group at another time.

University of Vermont.

F. A. Waugh.

### Cruelty of *Asclepias*.

THE Butterfly Weed, *Asclepias tuberosa*, is one of the most conspicuous plants in the Pines, and the flowers are seen all summer long on the different plants which peep out from under hedges and other shady places. The flowers vary in color from the deepest orange-red to pale yellow, and unlike the other species this plant has no milky juice. Another common species, *A. obtusifolia*, is quite different from *A. tuberosa* in its power to capture and hold insects until they die. Some of the other species have the same power in a more limited degree, but *A. obtusifolia* is by far the most cruel member of the family. The hoods surrounding the stigma which contain the nectar are comparatively short in this species, so that insects probing for the nectar often make a mistake and strike the cloven gland from which the pair of pollen-masses are suspended. Honeybees are the most common victims, and sometimes they are caught by the feet and sometimes by the proboscis. When caught by a foot in its struggles to free itself it often strikes another gland on the same or on an adjacent flower, when its frantic efforts increase until each foot is held as in a vise. The gland seems to be sensitive and to close more firmly about its victim the more it struggles, but if this is true it does not relax its hold after the insect is dead, as sensitive glands usually do. It requires careful work to extricate the insect in order to find just how it is caught. The pollen-masses are something like an old-fashioned pair of saddle-bags and hang by black-looking threads joined together at the summit, where it is attached to the gland which holds the insect. On loosening and pulling out this gland it brings with it the curious pollen-masses, and the foot or tongue of the insect is always found fast in the opening or slit of the gland, which seems to have closed around it. It has long been known that

the pollen-masses were liberated by the agency of insects, but why so many should be held prisoners and tortured in this cruel manner is one of the mysteries of plant-life. Not only bees but many small handsome butterflies are caught by the tongue and held until they die, and sometimes, but much more rarely, large beetles are caught. In one instance I found the large white-lined Saperda, the parent of the Apple-tree borer, held by three different flowers, and strong as this beetle is it was unable to free itself and so died. It is not at all uncommon to find Rose-bugs made prisoners.

The Swamp Milkweed, *Asclepias incarnata*, has this power to a certain extent. A few days ago several stems of this plant, with their numerous umbels of small pinkish flowers, were brought from the woods for class purposes and set on the porch in a jar of water. I soon noticed a strange fly flitting about them, the size of the common house-fly, but with a proboscis which could probe to the bottom of the hoods so as to reach the honey. It was probably some species of Chrysops, as it closely resembled the Golden-eyed Chrysops which sometimes so persistently flies about our heads in its effort to bite. But this species, although it had a wicked-looking proboscis, never attempted to bite, and its sole business was with the flowers. A score or more were about the plant, jostling each other in their eagerness for the unrifled flowers, so it seems that this fly is the main instrument in perpetuating this species of *Asclepias*. Occasionally a fly was caught by a foot and held for a moment, but usually it escaped, and it had done the work of extricating the pollen-masses from the cells so the stigma could be reached.

I have not studied this plant in its home in the swamp, but here on the porch this fly was the only visitor. I placed a jar of *Asclepias tuberosa* by the side of *A. incarnata*, and soon several butterflies and other insects alighted on the former, while they passed the latter by, or merely hovered over it for a moment without alighting. A fine Danaids butterfly came and sipped the nectar from *A. tuberosa*, scarcely deigning to notice *A. incarnata*, and yet she must have alighted on the plant in its home long enough to leave her eggs, for two of her baby caterpillars were feeding on the stems. It is remarkable that this butterfly recognizes all the species of *Asclepias* and makes use of them as food-plants for her children; for example, in appearance and in texture of the stems and leaves *A. tuberosa* is totally unlike *A. obtusifolia*. The two species seem to have nothing in common except the flowers and seeds. *A. tuberosa* has small green leaves without milky juice, while *A. incarnata* has a copious supply of the milky fluid, and yet before they bloom our butterfly knows the plants and uses them as food for her young.

As butterflies and wasps passed *A. incarnata* by, so the fly paid no attention to *A. tuberosa*. It knew without making the attempt that it could never reach the nectar at the bottom of the long hoods of this species. In my limited study of the Swamp Milkweed I did not find but one fly that it had killed and this was held by one foot. On extricating it I found the foot fast in the gland in the same way that *A. obtusifolia* holds its victims.

Vineland, N. J.

Mary Treat.

### Notes from Santa Monica Forestry Station.

CONSPICUOUS among summer-flowering Eucalypti growing here are the following:

*Eucalyptus citriodora*, or more correctly, *E. maculata*, var. *citriodora* (F. von Mueller), the lemon-scented Gum-tree. This is an erect, straight-stemmed tree, of rather slender and decidedly elegant habit, sparingly branched, but with numerous long, drooping branchlets, often over ten feet in length. The leaves are long and narrow—lanceolate-falcate in shape, nine to twelve inches long, and one inch broad at the widest part, tapering gradually to a blunt point. They are bright green on both sides, with a conspicuous midrib, yellowish green in the older leaves, maroon in the young foliage. The petioles and young branchlets are

also maroon-colored. The flowers are borne in few-flowered umbels, arranged in small, axillary, panicle clusters, which are set closely together (a panicle to every leaf) along the previous year's growth of the branchlets. Owing to the arrangement of the drooping branchlets, it often happens that the blossoms on a number of them are crowded together in a dense mass a foot or two in diameter, like a large swarm of bees. The individual flowers are about three-quarters of an inch across, in color creamy white. The seed-pods are about half an inch in length, truncate-ovate, with slightly flaring mouth, so as to be almost wen-shaped. The smooth bark, deciduous in thin flakes, is beautifully colored in delicate tints, varying from pale gray-green to lavender. Occasionally under the summer sun one of these tapering shafts warms up from its cool grays to a clear flesh-tint. Australian reports ascribe considerable utility to the timber of *E. citriodora*, and ornamentally this tree certainly ranks high, its general appearance at once suggesting the words graceful and elegant. Its flowers are borne profusely in May, June and July, at which time the tree is much frequented by bees. The leaves yield a volatile oil exquisitely lemon-scented. This perfume is not perceptible in the fresh leaves unless they are bruised, but it is gradually exhaled by drying leaves, which remain aromatic long after they are quite dry. Even the ashes of burned leaves retain the perfume. The best specimen of this tree in the arboretum here measures about fifty feet in height, with a spread of eighteen feet, and a girth of twenty-eight inches at one foot from the ground. This is the growth of nine years from planting, ten years from the seed, without irrigation.

*Eucalyptus cornuta*, the "Yate" tree of south-western Australia, is a tree of fairly rapid growth here, and of somewhat variable habit. It often displays strong tendency to divide at or near the ground, forming several stems unless trimmed. It has lanceolate leaves, slightly falcate, acuminate, five to seven inches long by one to one and a half inches broad at the widest part, dark green on both sides, shining, with a metallic lustre in sunshine. The flowers have very short pedicels, so that the many-flowered umbellate cluster is almost a globular head. In bud the long, slender, cylindrical, curved calyx lids or caps project on all sides like radiating horns, whence the specific name *Cornuta*. When these caps fall the long stamens spread, forming a pompon of a bright greenish yellow color. Often the blossoms are borne in large masses, and the effect is brilliant. The long, slender, projecting valves of the bell-shaped seed-pods continue the horned appearance to the fruit cluster. The wood of this species is highly valued in its native habitat, being there considered equal to the best ash. The flowers, like those of many other *Eucalypti*, yield a quantity of nectar, which is eagerly sought by bees, who visit the flowers even before the caps have fallen, and doubtless often help to push them off. The principal blooming season is in July and August, with a secondary season following about midwinter.

*Eucalyptus cornuta*, var. *Lehmannii*, as grown here, differs a good deal from the type. It displays the same tendency to divide into several stems, but is a much slower-growing tree with a symmetrically spreading crown of more open and scattered foliage. The leaves are oblong to narrowly obovate, mucronate, two to three inches long by about one inch wide, dull green on both sides, coriaceous, with petioles shorter than those of the type. The individual flowers are sessile, and the calyces united at the base, so that the umbel becomes in this variety a dense head. The horn-like calyx lids are longer, thicker, and often more curved than those of *E. cornuta*. The pompon is correspondingly larger and of a clear apple-green color. The seed-pods coalesce for almost their entire length, forming a spiny ball which remotely suggests a diminutive hedgehog. As with the type, the curious fruit clusters are long persistent on the tree, where they attract no little attention from visitors to the station.

*Eucalyptus tetraptera* is a dwarf species with curious

characteristics. The leaves are borne in tufts on the ends of the few branches, the old leaves dropping off as the branches elongate. They are ovate-lanceolate in shape, mucronate, very thick and coriaceous in texture, and dull-grass-green in color on both sides. They develop slowly, but when of full size are about eight inches long by two inches broad, with a mucronate point three-eighths of an inch in length. The midrib and petiole are thick and yellowish green in color, like the branchlets. Only one or two flowers appear at a time, and, like the leaves, they are very slow in developing. The fleshy calyx tube, prominently four-angled, green in the bud, flushes a brilliant red as the flower approaches maturity. Finally the pyramidal cap falls, displaying the incurved stamens with their delicately pink filaments tipped by purplish gray anthers. The seed-pods, when full grown, measure two inches in length by one and a half inches in breadth to outside edge of wings. They are quadrangular bell-shaped, with a pronounced wing at each angle, and are supported by a thick, flattened peduncle, bent downward. The brilliant red of the young fruit fades as the pod shrivels. So far the single specimen here has matured no seed. The bark is dull maroon in color and is deciduous in small flakes. The species probably has no value beyond its botanical peculiarities.

## New or Little-known Plants.

### *Coriaria Japonica*.

THIS handsome and interesting plant, the representative of a genus monotypic in its family, and composed of six or seven species, natives of the Mediterranean Basin, the Himalayas, northern China, Japan, New Zealand, Chili and Peru, promises to become an inhabitant of our gardens, as it has proved hardy in the Arnold Arboretum, where it was raised in 1893 from seeds gathered by Mr. Veitch the year before near Fukura, on the west coast of the central island of Japan, and where this year it has produced the flowers and fruit which appear in our illustration on page 343 of this issue.

*Coriaria Japonica*\* is a square-stemmed shrub which is said to grow to the height of ten feet. In the Arboretum, however, the arching stems are not more than two and a half feet long, and plants which I saw in the garden of the Forest School near Tōkyō were about the same size. I never encountered wild plants in Japan and they were seen by my companion, Mr. Veitch, only on the excursion which he made to the west coast.

The value of *Coriaria Japonica* as an ornamental plant is in the long racemose fruit, the showy part consisting of the accrescent petals of the pistillate flowers, which, becoming much thickened and succulent, enclose the five nutlets and form a five-angled, much-flattened, berry-like fruit half an inch in diameter. In describing this plant last year in *The Botanical Magazine* (t. 7509), Sir Joseph Hooker spoke of the cherry or coral-red color of the fruiting petals as its most interesting feature, the mature petals of all the other species being black or violet-black, his statement being enforced by the figure in a Japanese work on the useful plants of that country, in which the fruit is represented as bright red and described as "round, red, very pretty, but poisonous." Maximowicz, who has written a classical monograph of the genus *Coriaria*, described the fruit as black, with violet juice, and this character is confirmed by the plants in the Arboretum, on which the fruit was bright coral-red on the 20th of July, when it was from a quarter to a third of an inch in diameter, being then in the condition in which it appears in the figure of *The Botanical Magazine*; it then began to enlarge rapidly, and in a few days attained its full size, turning suddenly dark violet-black, the petals becoming filled with juice which dyes purple.

\* *Coriaria Japonica*, Gray, *Mem. Am. Acad.*, n. ser., vi., 383 (*On the Botany of Japan*) (1859).—Miquel, *Ann. Mus. Bot. Lugd. Bat.*, iii., 91 (*Prod. Fl. Jap.*, 255).—Franchet & Savatier, *Enum. Pl. Jap.*, i., 93.—Maximowicz, *Mém. Acad. Sci. St. Pétersbourg*, sér. 7, xxix., No. 3, 9, f.—*Bot. Mag.*, cxxii., t. 7509.

Fig. 45.—*Coriaria Japonica*.—See page 342.

1. A flowering branch, natural size. 2. A fruiting branch, natural size. 3. A staminate flower, enlarged. 4. A pistillate flower, enlarged. 5. A pistil, enlarged. 6. Vertical section of a fruit, enlarged. 7. A nutlet, enlarged.

The bark of the old stems of *Coriaria Japonica* is dark orange-color, lustrous and marked by numerous lenticels, while on the upper side of the shoots of the season, which are produced from the axils of the leaves of the previous year, it is rather bright red and yellow-green on the lower side. The leaves are opposite, ovate or ovate-lanceolate, acuminate, conspicuously three-nerved, yellow-green, and from three to six inches in length. The flowers, which are minute, are produced in elongated spreading racemes with the branches of the year from the leaf-scars of leaves of the previous year in clusters of two or three, either all female, or with one raceme of male flowers among them, and clothed with ovate or nearly orbicular leafy bracts, the racemes bearing male flowers being more slender than the others. The staminate flowers, which are borne on short pedicels, are green, and are composed of five minute ovate acute sepals much longer than the oblong-keeled petals, and of ten stamens in two series, with slender filaments which, short at first, lengthen rapidly after the flowers open, becoming much exserted, and linear-oblong introrse anthers inserted on the back. The pistillate flowers are borne on slender pedicels which are about a third of an inch long when the fruit ripens, and are subglobose, green, with five ovate sepals much longer than the broadly ovate imbricated petals rounded at the apex, five exserted slender purple spreading styles slightly thickened toward the apex, a pistil of five carpels each with a single anatropous ovule, which develop into five pale brown subreniform nutlets about an eighth of an inch in length, marked on the sides with five prominent anastomosing ribs. ## Foreign Correspondence.

### London Letter.

**LONDON PARKS AND CAFÉS.**—A movement has been started, headed by several influential people, to establish in the principal public parks of the metropolis, cafés of similar character to those of the parks of Paris and other Continental towns. Presumably the London crowds cannot find sufficient enjoyment in the trees, flowers and lawns of our parks and public gardens, and even the bands which now play on every day during the summer in most of them do not contribute all that is needed to make such places thoroughly attractive. I am inclined to believe that the crowds do find plenty of healthy recreation in our parks as they are, and that it is only the man of pleasure who now wants to add the flaunting café or biere-hal. Of course, the parks are for the people, and properly conducted refreshment halls are not out of keeping with their object, but whether the midnight revels of the Bois de Boulogne would be an improvement to Hyde or Regents' Park is a question of considerable doubt for Englishmen, at any rate.

**EARLIER OPENING OF KEW.**—From time to time, and more or less concurrently with the "big gooseberry stories," an agitation is started in favor of the earlier opening to the public of the Royal Gardens, Kew. The movement is purely local, and has for its main object the gratification of the leisured people residing near the gardens. The public are at present admitted from 12 o'clock, noon, till sunset, except on Sundays, when the opening hour is 1 o'clock, and on bank holidays, when it is 10 o'clock. Before these hours, with the exception of Sunday mornings, the gardens are open only to students, artists and visitors from a long distance, while to gardeners generally they are always accessible. It is difficult to satisfy these agitators, who look upon Kew merely as a pleasant sort of park where one can smoke or read comfortably under the shade of trees, that the principal object for which the gardens were founded, and are still supported, is the development of botanical science and the application of its resources to the enrichment of the empire, and that any further concession to the pleasure-seeker than those already made could only be at the expense of this object. If Kew is to be placed on

a level with Hampstead Heath or Epping Forest the time of its staff will be wholly employed in looking after irresponsible visitors.

**THE FRUIT CROP IN ENGLAND.**—With the exception of a few favored districts, the prospects of fruit-growers this year are bad. All the plums have fared very badly, some counties—Cambridge, for instance, which depends largely upon Green Gages, having scarcely any. Apples and pears are generally very weak. Cherries have not been so poor for years. Altogether, the outlook for the English fruit farmer this year is a melancholy one. We shall probably learn from the county council lecturer that failure is due to our bad methods of cultivation. Mr. R. D. Blackmore, writing after forty years' experience in fruit-culture, attributes this year's bad crop to the long summer drought experienced last year, followed by a wet September, which caused the trees to rush into a late second growth at the expense of the bloom-bud, which, though formed, was weak, and, consequently, when the flowers opened they succumbed to the first chill. Probably an excess of imported fruit will make up the deficiency, though what fruit we have now is at almost famine prices.

**CANNAS AND GLADIOLI.**—A novel and highly decorative use of the small-flowered forms of *Canna* with *Gladiolus gandavensis* is practised by the Parisian market-growers. The Cannas are planted in the usual manner in six or eight inch pots, and along with each one, two or three corms of the *Gladiolus* are placed; these grow with the Cannas and when in flower they combine admirably with their leaves, having a much better effect than even the best varieties of *Canna*, while their cost is only about a franc per pot. For the decoration of halls, cafés, restaurants, etc., they find much favor with the Parisians, and to the uninitiated the flowers of the *Gladiolus* serve just as well, probably better than the best of Cannas. It may be that the "trick" is well known to American market-growers, but I have never seen examples of it in England. It is certainly a cheap and easy method of producing serviceable material for ordinary decoration. A bed of common Cannas and this *Gladiolus*, or even mixed varieties, would be effective in the flower garden.

**HEMEROCALLIS AURANTIACA AND ITS VARIETY MAJOR.**—The variety has become universally popular with growers of herbaceous plants, its handsome bright green leaves in bold tufts and its enormous orange-yellow flowers placing it in the first rank among hardy plants for prominent positions in the border or flower garden. Some who have essayed its cultivation have expressed themselves disappointed with it, but this is no doubt because the plants are small and weak consequent upon rapid and exhaustive propagation. When full-grown in strong, loamy soil it is by far the handsomest of the genus. The type has remained comparatively unknown; indeed, some one lately ventured to doubt its existence, in cultivation at any rate. It was, however, first described by Mr. Baker in *The Gardeners' Chronicle* in 1890 from a plant in the Kew collection, where it still flourishes and has flowered freely this year. The variety is of Japanese origin and was introduced four years ago by Messrs. Wallace, of Colchester.

**CALCEOLARIA ALBA.**—A first-class certificate was awarded to this plant recently by the Royal Horticultural Society, Mr. Bennett-Poë showing some beautifully grown examples of it in pots. It was first brought into notice at Kew last year, where it flowered profusely on a south wall all through the summer, after having survived several winters without protection. On the strength of this the plant was supposed to be hardy, but last winter, although comparatively a mild one, proved fatal to all the plants left in the open at Kew. It is a native of Chili, and, therefore, likely to be happiest under cold greenhouse treatment, except in warm situations, such, for instance, as are suitable for the Chilean *Desfontainea*. It forms a dense shrub not unlike the common lavender, but softer in leaf and stem, and the flowers, which are borne in the greatest profusion in axillary clusters, are globular and pure white, resembling in effect the

fruits of the Snowberry, *Symphoricarpus*. Both seeds and plants of it are now to be had from the nurserymen.

**ERIOPSIS HELENÆ.**—This is a new species, according to Dr. Kranzlin, who describes it as the largest flowered yet found in the genus, resembling at first sight *E. biloba*, but more than twice as large. The pseudo bulbs are sixteen inches long, with one long and three short internodes, and the leaves twenty inches long by one inch in width; the scape is as long as the leaves, and bears a nodding raceme of yellow flowers with purple margins, and the lip is densely spotted with the same color. It has been imported from Peru by Messrs. F. Sander & Co., St. Albans, with whom it has lately flowered. The genus is not one of the most popular with English cultivators, the species hitherto grown being shy of flowering. Possibly this new species may prove more satisfactory. Dr. Kranzlin says "it is undoubtedly the finest species of this small genus."

**BRITISH FERNS.**—The numerous varieties, many of them very beautiful, of British Ferns now in cultivation, and for the origin of which we are indebted to the careful cultivation, selection and, it is said, cross-breeding of a few enthusiasts, have increased in favor, especially among amateurs. We have now a society devoted to them, calling itself the British Pteridological, and having for its objects the dissemination of a wider knowledge of the merits and beauties of British Ferns and their varieties, a regulation of their nomenclature, the encouragement of their general culture by providing a means, at least once a year, for an exhibition of them and the meeting of their finders and raisers under one roof for the exchange of cultural knowledge and specimens. Mr. E. J. Lowe, F. R. S., has raised some most extraordinary varieties, especially among *Scolopendriums*, and he has written several interesting volumes upon the peculiarities of growth and variation among ferns generally under artificial cultivation. The president of the society is Dr. Stansfield.

### Gooseberries.

**W**HILE this season has not been altogether favorable to some fruits it has suited Gooseberries to a nicety. The cool, showery weather in May and June swelled out the fruits to more than double the size to which we usually grow them, and the bushes bore such an enormous crop that they were severely thinned when about half-grown, this green fruit proving acceptable for sauce and pies. We have only found one or two varieties to be thoroughly reliable. Of the foreign or English sorts, *Whinham's Industry* is easily the best we have tried; some sorts bear larger berries, but for heavy annual crops, free growth and a total absence of mildew we considered *Industry* the best foreign variety. From bushes planted in the fall of 1894 we gathered an average of twelve quarts of ripe fruit from each plant, besides the green fruit picked early in the season and that which burst during the wet weather. We find this variety succeeds best when not planted in a fully exposed place, but where the plants get sunshine about half the day. Full sunshine during all of the day causes some of the berries which are most exposed to be scorched and to drop off.

Among American varieties we think highly of *Columbus*, sent out by Ellwanger & Barry, of Rochester, New York, four or five years ago. The fruit is much larger with us than that of *Industry*; skin greenish yellow and smooth, and the foliage is large and smooth. It is a heavy cropper and the most robust grower of any sort we have tested. *Triumph* is a large golden-yellow variety of size similar to *Columbus*, and is an equally robust grower and great cropper. Both these varieties have very thick skins, and thick skins seem to be an essential quality of any gooseberry which is of use in America, as thin-skinned sorts are literally cooked on the bushes by scorching heat from the sun in July. *Downing* is an old reliable sort, much smaller than *Triumph* and *Columbus*, but a reliable cropper, and the fruit ripens some days earlier than that of any other kinds we have tried.

Gooseberries prefer a cool and rather moist climate. We always mulch our bushes after growth commences and leave

this surface-dressing on until fall, when it is removed. The bushes are then pruned and a coating of good rotten manure is given them. Like all small fruits, Gooseberries have large quantities of fine fibrous roots near the surface of the soil and no digging should be done among them. Stirring with a hoe to keep down weeds and to loosen the surface is all the cultivation needed. During the growing season we give our bushes several soakings of liquid-manure after heavy rainfalls, and this labor is fully repaid by increased size of the fruit.

Gooseberries can be propagated in a variety of ways, but cuttings make the most shapely bushes. The strongest and best ripened shoots should be selected. We prefer cuttings about a foot long after the top has been shortened back. We rub off all lower eyes and leave only four to five at the top of each cutting. If it is not desired to plant them out in the fall they can be heeled into a cold frame; they should be tramped firmly and never allowed to become dry. By April 1st they will be found to have callus formed and can be planted out in any good garden soil, and a moist location should have the preference. In dry weather water must be given or few of the cuttings will grow. Propagation by layers and suckers will give larger bushes in a short time, but the bushes are never shapely and constantly send up suckers from the base. We prefer fall planting for Gooseberries, and, indeed, for nearly all other fruits, and move them as soon as they shed their foliage.

Taunton, Mass.

W. N. Craig.

### Fern Notes.

**F**EW Ferns require repotting at this season, except seedlings or young stock that is much root-bound and may be needed for use in Fern-pans, or for table or mantel decorations during the winter. Young plants of the common species used for these purposes, for example, *Adiantum cuneatum*, varieties of *Pteris*, *Anychia Japonicum*, *Davallia tenuifolia stricta* and several of the *Aspidiums*, may be potted on at any season of the year when grown in a temperature of sixty degrees, and will grow away freely, while old plants of the same species grow but little during the fall and winter months, and may receive a severe check from having their roots disturbed too late in the season.

Watering should be done early in the morning at this season, as the night air is damp, and plants watered late in the day have no chance to dry off, so that damping of the foliage follows. Abundant ventilation, both day and night, is essential, and even tropical species require plenty of fresh air. For many species of Ferns the soil is of much less moment than the condition of the atmosphere, though good drainage is necessary for the health of the roots. For the ordinary decorative species referred to, a good soil is a light loam enriched with some thoroughly rotted manure from an old hot-bed.

The sowing of Fern-spores of any delicate species after this time of year is ill-advised, as there is greater risk of the tender young plants damping off during the shorter days of early winter than in the spring. Their growth is at best quite slow in winter, and but little time is gained by fall sowing. As an instance of the facility with which Fern-spores may be carried from place to place I recall a greenhouse which had contained no Ferns, and where no less than twenty-six species and varieties were growing beneath the benches within eighteen months from the time of building the house. The nearest Fern-house to the house in question was fully one hundred feet distant, and the spores were doubtless transferred in the clothing of persons who passed from one house to the other.

Of course, all Ferns cannot be grown with equal success in the same house, for many cool-house Ferns are unresponsive in a high temperature, and others from a tropical habitat do not flourish when kept too cool. The medium temperature of fifty to fifty-five degrees, maintained throughout the winter, will make it possible to grow with satisfaction quite a large and varied collection of these plants, and a house of this character well cared for will prove one of the most enjoyable in an establishment.

The so-called Boston Fern, a form of *Nephrolepis exaltata*, has become a great favorite for the window garden as well as the greenhouse during the past two or three seasons, and deserves the distinction. It is a plant of easy culture and rapid growth, and makes an interesting specimen in a pot six inches or more in size. In common with the other Sword Ferns, this *Nephrolepis* enjoys good living, and grows finely in strong loam. When pot-bound it is benefited by watering with weak liquid manure about once a week. *N. cordata compacta* and *N. davallioides furcans* are also largely grown for decorative purposes; the first-named is probably the better house plant,

and makes a good specimen even in a four-inch pot. While curiosities or monstrosities such as the birds, beasts and reptiles formed by the Japanese from the rhizomes of *Davallia Mariesii* cannot be recommended, grown in a more natural manner this species is useful for the cool fernery, though nearly or quite deciduous. In fact, the *Davallias* generally are interesting, and *D. bullata*, *D. Canariensis*, *D. pentaphylla*, *D. tenuifolia stricta* and *D. elegans* may all be grown to advantage in a temperate house, either as pot-plants or in baskets. The latter method gives a better opportunity to dispose of the straggling rhizomes by pegging down than in the case of those grown in pots.

Holmesburg, Pa.

W. H. Taplin.

### Gloxinias.

SEEDS of *Gloxinias* are usually sown during autumn, though sowing in spring is becoming more common. One of the chief advantages of autumn sowing is that all the plants come into bloom when a suitably low temperature can be maintained. The flowers are susceptible to flagging, and the blooming period is considerably shortened when it occurs during the hot, drying summer months. It is also somewhat difficult to prevent the plants from becoming drawn if a heavy shading has to be used. The plants are not so apt to suffer from flagging influences so long as sufficient water is provided, but if neglected in this respect disfigurement of the foliage will quickly follow.

February is a favorable time for sowing the seed, and the temperature of an ordinary propagating house is sufficiently high for starting them. The seed-pans intended for use must be thoroughly clean and dry, so as to insure against any germs of fungus. If this precaution is not taken the fungus will soon make its appearance on the surface of the soil and cut off the little plants shortly after they have started. Much of what is commonly known as damping can be traced to this source, though this is by no means the only source from which it proceeds, and careless watering will often cause it. We do not water on the surface, but supply the moisture from below by keeping the pan standing in a saucer of water. The dangers of damping may be considerably lessened by pricking out the seedlings into fresh soil while they are as small as they can possibly be handled. A good compost for the seeds is composed of finely sifted leaf-mold and silver sand in about equal portions. The same compost may be used for the first pricking out, but for subsequent shiftings less sand will be needed, and for the later pottings well-rotted sod soil should be used with about one-third of the compost. We sift this soil also, as the roots are rather fine.

After the plants are established in three-inch pots we place them in a cold frame, where they grow more freely than in any other place in which we have tried them. Removable shades must, of course, be provided, and light sprinkling twice daily during bright sunshiny days, to maintain a suitable atmosphere. We usually leave the plants in frames until flowering commences, when they are removed in batches to a house where they can be displayed to the best advantage. We choose the coolest house possible for them and provide suitable shading. The poorer varieties are discarded or set aside as soon as they show their character, to prevent good varieties being crossed by them. We save seeds from our own plants, and this is by no means a troublesome matter, as they are produced freely if the flowers are kept dry.

Tarrytown, N. Y.

William Scott.

### Hardy Perennials.

NOT a few of the perennial species of *Coreopsis* are quite hardy, and as they flower very freely during a long season they are specially suited for use as border plants. Probably the best-known species in gardens is *C. lanceolata*; it is altogether hardy and thrives in any good soil, and the flowers continue from early summer until frost. Full-grown plants range from one to two feet in height. The flower-heads are of a shining yellow color, and on well-grown plants measure from two to three inches across. They are produced on long, naked pedicels which add much to the effectiveness of the plants, and are useful for cutting. This *Coreopsis* produces an abundance of seeds, and young plants are easily raised from them. Sown early in spring the young plants may be set out into the ground in the early summer and will provide a good supply of flowers in the fall.

Another satisfactory species for the garden, though but seldom seen, is *Coreopsis delphinifolia*. This distinct southern species is quite hardy without protection in this vicinity, and grows luxuriantly. The plants reach a height of two feet, and its upright stems are thickly clothed with deep green leaves

divided into three sessile leaflets. The yellow flower-heads are not quite as large as those of some of the other perennial kinds, but they are produced plentifully. In a rich sandy soil, where there is abundance of light, this plant makes a good border perennial.

*Coreopsis verticellata* has slender upright stems and finely cut foliage, with a neat bushy habit. Its height varies from eighteen inches to two feet, and the stems are set off by dark green and finely cut leaves, which are produced in whorls. The deep yellow flower-heads measure about one inch and a half across and are most plentiful during late summer and early fall. *C. senifolia*, found from North Carolina to Florida, is quite hardy here. The stout, vigorous plants grow to be three feet tall and bear good-sized leaves, which are divided into three entire sessile divisions. The dull yellow flowers are of medium size.

*Coreopsis grandiflora* is the best of the perennial species, and where it will grow and thrive it is one of the showiest of the low-growing compositæ for the border. I regret that it does not thrive here as well as many of the other species. It does not live and has to be grown from seed frequently. I notice that Dr. Asa Gray, in the *Synoptical Flora of North America*, says that the root is sometimes annual, and this is possibly the reason for its short existence. It resembles *C. lanceolata* in many of its parts, but the main distinction for garden purposes is that its flowers are much larger and the ray florets are more deeply cut. Other species grown here that are quite hardy and reliable are *C. auriculata*, *C. pubescens*, *C. tripteris* and *C. rosea*.

The wild Monkshood, *Aconitum uncinatum*, when planted in a favorable position, makes a splendid mass of dark blue. It is the best plant bearing blue flowers at this time. A slightly shaded spot and rather rich, moist soil here suit it best. The stems of this Monkshood are not very stout, and need staking to keep them erect, so that the flowers can be seen to better advantage. Our plants are from four to five feet high, well covered with dark green leaves, and the dark blue flowers are produced in large showy racemes.

*Statice latifolia* is again lending its grace and airiness to the border with its broad, spreading panicles of blue flowers. This is the best hardy perennial species in the genus. Large plants make a striking contrast and pleasing effect among more substantial-looking plants. A deep, rich, somewhat moist soil is necessary, and the plants should not be disturbed often. Another species well worth growing is *S. elata*. Though hardly as pleasing as *S. latifolia*, it is, nevertheless, a desirable border plant. It is slightly taller and not as graceful or airy, but it has large showy panicles of small blue flowers, and makes a vigorous plant. Besides the use of these delicate sprays for intermixing with other flowers, they are also sometimes dried like the "Everlastings."

*Rudbeckia speciosa* makes a rich display in the border when large clumps are planted from six to eight yards apart, and the glowing masses of bloom are showy at a considerable distance. The flower-heads of this Cone-flower are a rich orange-yellow with a showy velvety maroon centre, and measure from three to four inches in diameter. They are borne profusely in dense masses. The compact plants are about two feet in height and thickly covered with ovate lanceolate leaves. It thrives best in an open position in light rich soil.

*Veronica longifolia*, var. *subsessilis*, deserves to be classed among choice garden perennials. Like many more of our showy garden plants, it comes from Japan, and is perfectly hardy here. When well grown it attains a height of from three to four feet and its stems are terminated with large dense spikes of deep purple-blue flowers, which make it effective. *V. Virginica* is a tall-growing species and a native plant. Well-established plants are conspicuous at this time with their large terminal spikes of white flowers.

Harvard Botanic Garden, Cambridge, Mass.

Robert Cameron.

### Rock Garden Notes.

ONE of the handsomest plants on the rockery now is the Mexican *Hunnemannia fumariæfolia*. The large yellow flowers are not unlike the Californian Poppy, but have more substance, and the flowers last several days after being cut. The plants are not entirely hardy here, though they come through some winters in good condition, and some half-decayed leaves thrown over the roots help them to winter over. If seed is started in the fall it should have the benefit of a warm house; spring-sown seeds delay the flowering period until the beginning of July.

Owing, I suppose, to the moist season, the varieties of *Achimenes* have done exceptionally well this summer. Care

is taken to plant them in somewhat shaded situations, otherwise they neither grow nor flower quite so freely. The plants make such a host of underground tubercles that it is only necessary to lift a few of them in the fall by inserting a trowel under the middle portion of the plant, and transfer them with the soil to a box. The kinds should be kept separate, and the boxes stand in a moderately warm dry place during winter.

*Papaver rupifragum* is almost past its second blooming since the plants were put out in the spring. The seed capsules were cut off after the first flowering, the stems cut rather close, and they soon branched out again, producing hundreds of rather small flowers on each plant. The flowers are dull red, the leaves grayish green. *Salvia Pitcheri* is only coming into flower. This lovely species needs renewing every now and then to have it at its best.

*Potentilla fruticosa*, the native shrubby Cinque-foil, now in full flower, makes a desirable shrub for use among rocks. It can be trimmed to any shape or cut down annually if need be. *Spiræa Anthony Waterer*, after two years' trial, has fulfilled all the claims made for it. Since early spring it has never been out of bloom, and the bushes are not a foot high yet. Plants started into growth indoors early in the season will give a cutting from nearly every bud. They are as easy to root as *Coleus*.

*Hydrolea spinosa* being a blue flower and a very pretty one should have a place in every large garden. It is apt to run to seed in a short time if it is not watched. If planted in clumps it is well to nip off half the shoots when they get to a certain height and let the other half bloom. By the time the first lot are done flowering the others will take their places, when those which flowered first should be divested of their seed vessels. These shoots will bloom again later on.

*Anoda acerifolia*, a malvaceous plant from Mexico, is evidently closely allied to *Callirhoe*. The flowers are about the same size and color as those of the well-known *C. involucrata*. Instead of a few straggling stems, as is the case with the *Callirhoe*, the *Anoda* will cover several square feet with a dense mass of creeping shoots. It is just coming into bloom now, and until checked by cold weather it will be an attractive object. It is not hardy with us, but it ripens seeds in abundance.

*Lilium lancifolium roseum* and *L. album* are among the most satisfactory of the genus with us, coming up regularly every year and producing six and eight blooms to the stalk. A top-dressing of manure each fall seems to suit them. *L. Michauxii* does fairly well, and *L. auratum* succeeds only the first year after planting, dwindling each season afterwards until it dies.

*Plumbago Larpentæ*, or as it is now called, *Ceratostigma plumbaginoides*, is, perhaps, the prettiest of our blue-flowered hardy perennials. It is well adapted for rock-work, as it grows only a few inches high, and in favorable situations it blooms from midsummer until frost. This species was grown as a stove plant for a long time after its introduction. Although perfectly hardy it does best in countries having a high summer temperature.

*Crotalaria ternatea* has flowers quite as large as the native *C. Mariana*; the color is blue or white. It is best treated as an annual, and if sown early it will cover an astonishing amount of space.

Botanic Garden, Washington, D. C.

### The Green Scale of Coffee.

To the Editor of GARDEN AND FOREST:

Sir,—It seems desirable to record the fact that the green Coffee scale of Ceylon, so destructive in that country, has been found on Coffee in Sao Paulo, Brazil, by Dr. von Ihering. The specimens, just received from the S. Paulo Museum, agree excellently with others sent from Ceylon by Mr. E. E. Green. The insect is a species of *Lecanium* (*L. viride*, Green) very similar to our common *L. hesperidum*, but considerably smaller, and of a green color.

Mesilla, N. M.

T. D. A. Cockerell.

### Hardiness of the Montbretias.

To the Editor of GARDEN AND FOREST:

Sir,—I read with interest in your issue for August 18th the note on *Crocasmia aurea imperialis* by Mr. Gerard, whose articles I have greatly enjoyed and profited by. Mr. Gerard states that "the Montbretias only have been tried here, but

have never survived in the open." In New Hampshire we have a severe climate, occasionally twenty degrees below zero, and no protecting snow, perhaps, at the time, and the ground freezes to the depth of from two and a half to four feet. Two years ago this fall I set in the open a lot of *Montbretia crocosmia* flora, and gave them a covering of leaves only. They have passed through two severe winters, have greatly increased in numbers, and to-day are in full bloom. Again, the year before I caused to be planted in a cemetery in which I am interested a lot of *M. Pottsii*, giving them the same treatment, and with about the same results, though a few never came to the surface. Mr. J. Woodward Manning, of Reading, Massachusetts, when visiting the cemetery with me spoke of *M. Pottsii* as being very tender, and was surprised to see it thriving here grown in this way. The soil in each case is a sandy loam with good drainage, with full exposure and no protecting trees or fences. This winter I propose trying a few plants wholly unprotected, to test the results of this treatment.

Nashua, N. H.

C. W. Hoitt.

## Japan Plums.

To the Editor of GARDEN AND FOREST:

Sir,—This new race of garden Plums has been regarded with much interest recently, principally, perhaps, because of the claim made that the Japan Plums do not become a prey to the black-knot fungus that has made it practically impossible of late years to grow the older race of garden Plums.

We have an almost complete set of these Plums under trial so far as they are now in commerce, and this year have been able to judge what the fruit is like. *Prunus Simoni* is the progenitor of this race, and while that species is a rather poor fruit it is very distinct, both in shape, flavor and habit of growth. There is an unpleasant astringency in the skin of the fruit that affects preserves even, and it is necessary to peel the fruit to avoid this unpleasant flavor. But the value of *P. Simoni* is as a fruit for hybridists to work with.

The best Japan Plum we have found thus far is the Burbank, so named after its raiser, and which seems to be a cross between *Prunus Simoni* and one of our native Plums. There is certainly no finer plum in cultivation to-day if we take into consideration its hardiness, free growth and the large size and excellent flavor of its fruit. The tree was in full bloom this spring when a severe frost occurred that ruined most other trees in bloom, but the Burbank Plum came through well and did not seem hurt in the least. The growth made in the first two years after planting was phenomenal, about six feet all over the tree, and no signs of winter-killing were visible. The fruit is as large as a moderate-sized peach, with yellow flesh and a very small stone. We have decided to graft all the older kinds of Plum with the Burbank next spring. This will have the effect of modifying the growth somewhat, and may eventually be an unequal union of stock and scion. This resulted when *P. Simoni* was worked on the common sorts that had been subject to black-knot, but otherwise the effect was good.

Another Plum we have fruited to a limited extent this year is the Kelsey. It is a much smaller fruit than the Burbank, greenish yellow in color, somewhat like the Green Gage, but not so good in flavor, and it is not a very vigorous grower. It will need another year's trial before we can tell of its value with certainty.

The Abundance Plum is said to excel the Burbank in all respects. I shall be surprised to find this a fact, and it does not now seem impossible. It is highly recommended for planting for market, and a great many of the trees have been set out in this district. We have not fruited it yet, but hope to next year. Among others that are on trial are the Wickson and Satsuma, of Japanese origin. All have proved hardy, free from disease and not subject to any insect attacks. The only objection to be brought against them is their spreading habit, but if this characteristic had been known earlier it could have been corrected by pruning. The knife should be used freely on young trees to bring them into shape and keep them compact, so as to prevent breakage to the trees hereafter by heavy crops of fruit.

To those who wish to grow Plums in the garden I advise the trying of a set of these Japan Plums, as there seems to be good reason to believe that they will be the Plums of the future when the black-knot has wiped the older race out of existence. This pest is hard to control when the hedgerows are full of native species of *Prunus*, and these trees serve for its propagation. Fruit growers have considered it hopeless to be able to fight the fungus, and are planting the Japanese Plums in place of the native kinds. In planting it should be borne in mind that a much greater distance is needed between the trees

than between other Plums—at least eighteen feet when mature growth is reached by the trees. The curculio seems to be quite as troublesome in these new Plums as on the older ones, though we had hoped much from the thicker-skinned fruit. But to have clear-skinned plums the curculio must be fought in early summer, when it is doing its work. We lost but few from the stings, but the fruit was disfigured.

South Lancaster, Mass.

E. O. Orpet.

### Notes.

The annual meeting of the West Virginia Horticultural Society, Sheep-breeders and Wool-growers' Association, together with the State Board of Agriculture, will be held at Martinsburg, West Virginia, from October 12th to 15th.

The best cucumbers in market now are those grown under glass near Morganville, New Jersey, the heavy rains of the past weeks having injured the field crops of this vegetable. Choice cauliflower, from western New York, costs thirty cents a head. Small yellow tomatoes, for preserving, and immense yellow cucumbers, known in the trade as mustard pickles, are early fall offerings, and new Brussels sprouts from Long Island.

The sales of western fruits this summer have been exceptionally large here, and those of last week surpassed all former records. Altogether, 123 carloads from California, Oregon, Washington and Utah were sold. Grapes, peaches, plums and Bartlett pears comprised the bulk of these shipments, which included the first Zoe, Forelle and Comice pears of this season, with considerable quantities of Seckel and Buerre Clairgeau pears. Two carloads of Late Valencia oranges were a remarkable item in the long list of California fruits.

The California correspondent of the New York *Tribune*, in a dispatch to that journal a few days ago, stated that the Big Star Beet-sugar mill which will start up next January near Martinez will not only make sugar from beets, but will refine cane-sugar from Hawaiian plantations that are not controlled by the present monopoly. It is estimated that this year's crop, which is outside the influence of the trust, amounts to 200,000 tons, of which a large fraction will come to this factory. Stockton is also to have a beet-sugar factory, the plant of which will cost over \$500,000. Its capacity will be 500 tons. The soil of the rich San Joaquin Valley is specially adapted to sugar-beets, and tests have shown that the saccharine percentage is very large.

Plants sometimes acquire a reputation for being difficult subjects to grow or flower when they may only require some slightly special treatment or even a particular location. *Cattleya Dowiana* has a reputation for miffiness, but Mr. Gerard, who recently sent some of its handsome flowers to this office, states that it has bloomed regularly in August in his greenhouse with no special care, except that it is grown in a basket, and is retained as far as possible in the same situation, a place where it finds much pure air and a moderate amount of light. This *Cattleya* is one of the most distinctly colored of the family, and is a pleasing change from the ordinary purple kinds. The very large flowers have petals and sepals of nankeen-yellow, and the large lip is a rich dark crimson, finely veined with gold. The petals and lip are both beautifully fringed.

The local receipts of apples for last week amounted to 11,342 barrels. Duchess of Oldenburg, Gravenstein, Maiden's Blush, Codling, Pound Sweets, Orange, Holland and Twenty-ounce Pippins were the principal sorts, with some specially large and showy Alexanders. The best peaches now come from western Maryland and from Missouri and Arkansas, although the main dependence is, of course, on the large supplies of more ordinary quality from Maryland and Delaware. Concord, Niagara, Delaware, Wyoming, Worden, Moore's Early and Champion grapes are all now in season and come from the interior of this state; three-pound baskets sell for fifteen to forty cents, according to the variety and quality. Hot-house grapes, nectarines and figs, apricots from Arizona, and large alligator pears are among the special offerings in choice collections of fruit.

Watermelons continue plentiful, and in this city an ordinary day's business last week comprised twenty-one carloads and 43,086 melons by steamer, besides wagonloads from near-by farms. Jenny Lind and other varieties of muskmelons are coming in large quantities from Maryland, Virginia and New Jersey. Among the most notable offerings of fruits now seen are some Montreal muskmelons. These are not only of immense size, but superior flavor and quality, due in

some measure to their quick growth in the longer days of the brief Canada summer, and seeds of these famous melons fail to give as large and as good fruits in this region. Six of these melons, with the packing of hay, fill a box which would hold two bushels and a half, and \$2.00 each was the price asked on Saturday in the fancy-fruit stores. An exceptionally large one weighed twenty-four pounds, an average weight being from fifteen to eighteen pounds. Some of the so-called banana melons, from New Jersey, were seen in Washington Market last week, where they were regarded mainly as a curiosity, though a few found sale at twenty-five cents each. These melons are from twelve to fifteen inches long and three to five inches through, with greenish yellow and rather smooth skin, and fine-grained flesh without distinctive or rich flavor. Seeds of this melon were formerly offered in the catalogues, but no mention has been made for several years, owing to lack of demand for them.

In a late number of *The Cultivator and Country Gentleman*, Mr. W. C. Rockford, of Genesee County, Michigan, gives an interesting account of his experience last year in husking some 3,000 bushels of corn by machine. The cost of husking by the usual hand method is three to four cents a bushel in that section, and a saving of labor and probably of money was anticipated, since husking and shredding was accomplished at one operation. A powerful machine with steam motor was used, and the husking was well done, though some of the kernels were shelled in the process. But the shredding of the husks and stalks for fodder was the main consideration in this experiment, and while the stalks were crushed and flattened, they were not cut as fine as in the ordinary cutting-box operated by horsepower. The stalks were allowed to become thoroughly dry before husking, and the crushed fodder was stored in small stacks to prevent any possible souring. No trouble was experienced in this respect, although several days of heavy rains occurred at the completion of the work, and the stacks shed water almost perfectly. In this first year's experience with this machine an average of 400 bushels of very heavy corn was husked a day, and the cost, including labor and boarding, amounted to nearly five cents a bushel. Mr. Rockford's conclusion is that unless a machine can be had which shells the kernels less than this one did, the machine method is not practicable when the corn is intended for sale. There is also less waste of fodder when it is more finely cut by the old method, though the machine-cut stalks in some parts of the country are baled and sold in cities, where there is a growing demand for such provender at prices which compare favorably with hay.

At the annual meeting of the American Association of Economic Entomologists held in Detroit, August 12th and 13th, Dr. R. O. Howard, of the Department of Agriculture, Washington, District of Columbia, speaking of the effect of temperature upon the hibernation of injurious insects, stated that in experiments with such insects in cold storage a consecutive cold temperature proved favorable to successful hibernation, while a low temperature followed by a high one with a return to a low one, almost always resulted in death to the insect. The conclusion is that a steadily cold winter with a temperature even much below the average will usually be followed by an abundance of insects, and that after a winter characterized by alternate cold and warm spells, fewer individuals will survive. Besides a brief account of the practical work done by the Gypsy Moth Commission in Massachusetts, Professor H. K. Kirkland, of the Board of Agriculture of that state, reported that arsenate of lead seemed to be quite as effectual as Paris green as an insecticide, with cheapness in its favor, since it costs but seven cents a pound, whereas Paris green costs twenty to twenty-five cents. Other interesting subjects considered were The Weights of Bees and the Loads they Carry, in a paper by Professor C. P. Gillette, and The Lac and Wax from Insects, on which subject Dr. Howard said that while in some oriental countries industries of considerable importance have resulted from the use of these secretions, no such use has yet been made of them in this country, although several species of the scale insects yielding these substances exist in the southwestern part of the United States and may prove to have commercial value. For example, there is an almost unlimited quantity of a bark-louse of this class found upon Oaks of several species in California, and chemical investigations which are now being made have already demonstrated that wax of good quality may be dissolved from the insect mass by chloroform, and that an insoluble residue is left which much resembles rubber in its physical proportions. These chemical investigations are being continued, with much interest, for the supply of rubber is said to be decreasing, owing largely to waste in gathering it.

### Native Plants for Ornamental Planting.

WE spoke last week of the advisability of using indigenous plants for the adornment of small country places rather than the showy exotics and abnormal garden varieties which are generally preferred. We had in mind, especially, the resources of those beautiful thickly-wooded districts in northern New Jersey and southern New York where many residents of Manhattan have recently created summer homes for themselves. Let us now consider a little more carefully the supplies which Nature furnishes in these regions and the ways in which the owner of a small place would profit if, turning his back on the nurseryman and his seductive catalogues, he were wise enough to make use of them.

Where the forests have recently been cut away some of the largest and most vigorous trees have usually been retained—Sugar Maples, Hickories, Hemlocks, Beeches, Chestnuts and Oaks of several kinds; trees which had beaten their associates in the local struggle for life, and were therefore the finest that the given piece of ground supplied. But from about and beneath these their lesser companions have been removed; and then, where further planting was desired, trees from other regions or showy garden specimens have generally been introduced—Swiss and Austrian Pines, Blue Spruces from the Rocky Mountains, Lawson's Cypress, Beeches of weeping habit or with copper-colored foliage, *Prunus Pissardii*, cut-leaved Birches, striped *Negundos* and others. Little attempt has been made to group these introductions so that they will show at their best; and even if they were as agreeably arranged as possible, they would not harmonize with the native trees as well as would other species brought in from the native forest.

Here might be found in profusion, as has already been suggested, trees of various sizes and of the most diverse kinds of beauty—the Shad-bush and the Dogwood to bloom in early spring; the Yellow Birch, bright of bark and delicate of foliage; the Sassafras, with its peculiar leaves and varied tints of green; the White Pine, more delicate in its foliage and more picturesque in its habit than its Swiss and Austrian cousins; the Wild Cherry, with its profusion

of fruit; the Hop Hornbeam, with its tassels of seed, and many more besides. All of these would be more sure than foreign trees or garden varieties to grow finely under local conditions, and much more sure to harmonize well with the larger Maples, Oaks and Chestnuts. And there are other reasons also why it would seem, an intelligent planter should prefer to introduce them in his ornamental grounds. He need not fear that if he confined himself to them his place would lack individuality—would look too much like a corner reserved from the original forest, too little like a creation of art. In the forest secondary trees do not get a chance to develop fully and finely. They grow as they can, in thin and straggling shapes, sometimes stunted of their height, or often drawn out by their search for light into tall stems merely topped by a narrow head of foliage. Of course, even thus they minister to beauty, bringing their several quotas to the compound charm of the forest. But it is only here and there in the thinned border of the woods, or surviving by chance along the brookside or the margin of a meadow, that they give a hint of the beauty they might attain under freer conditions, and this can hardly be completely shown until they are placed in isolation where the hand of man can tend them. The Dogwood of the forest spreads admirable sheets of bloom among the stems and branches of its crowding neighbors. But if planted on a lawn it reveals unsuspected beauties of shape and foliage. The Red Cedar, which may be shapeless in the woods, will assume a strict pyramidal habit of admirable outline if grown by itself, and few imported pyramidal trees can do better service where a somewhat formal feature is desired. The Yellow Birch cannot reveal its possibilities of charm unless it is seen by itself, the delicate leafage sweeping the grass and the brilliant bark gleaming through it. The young White Pine, most often ragged and scrawny as it grows amid other close-pressing trees, is a compact, symmetrical mass of feathery needles when it has a better chance; and its progress from this shrub-like phase to the bold picturesqueness of its later years is one of the most interesting things in nature for the observant eye to watch. And so it is with every native tree: give it a better chance than the struggle for life of the forest affords and it will surprise us with unsuspected charms. It ought to be more interesting to an intelligent planter thus to develop the beauty of indigenous trees which will quickly and gratefully reward his care, than to cultivate exotics which are less well suited, perhaps, to local conditions, and with which he can hardly hope to achieve the same success that has been achieved by the practiced nurseryman from whom he has purchased them. To feel that he is completing Nature's intentions in developing the plants with which she has supplied his locality more perfectly than she is able to do, ought to satisfy him better than the effort to grow plants which she has meant should grow under different conditions, and to combine things which she has kept far apart. And, we repeat, the variety which he desires in his grounds may thus be amply secured.

The current preference for exotics and garden varieties seems even less comprehensible in regard to shrubs than in regard to trees. The Golden Elders, the piebald *Retinosporas*, stiff *Altheas* and coarse panicked *Hydrangeas*, which we see repeated in such wearisome profusion, are really less beautiful than our native shrubs—the Mountain Laurel, the *Viburnums*, the *Sumachs*, the *Elders* with black berries or red, the *Spiræas*, the New Jersey Tea, and a score of their congeners. And with vines and creepers the case may be even more strongly put. The region which we have now in mind supplies some of the most beautiful creeping and twining plants in the world; several kinds of Grape, one with broad, slightly lobed leaves and another with darker leaves deeply lobed into an almost architectural form; the Virginia Creeper, the Bittersweet, and the Virgin's Bower, a wealth of starry white blossoms in August and later loaded with long tufted seeds. Yet place after place in this region may be examined and no creeper be

seen, either on house or fence, except Honeysuckles (usually of the showy golden-leaved variety) and the Japanese Ivy of which we almost grew tired within the city's limits before the summer had really begun. Would not variety as well as beauty be better served if our native wealth in shrubs and vines as well as trees was utilized instead of the products of the commercial gardener?

Certainly in one important direction the interests of variety would be far better served, as regards both trees and shrubs, were native products more appreciated. The excuse that is offered for the employment of exotics and garden varieties is often that diversity in color is attractive. Therefore, Nature's harmony of summer greens is disturbed by masses of red and yellow and blotched-leaved plants. But while confusion is thus secured, real variety is not. Such bright-leaved plants remain the same from spring's beginning until autumn's end, and their very brightness, making them more conspicuous, only makes them seem more and more monotonous as the weeks go by. The real way to secure variety is to obtain plants which from week to week or month to month will change. Those which bear beautiful blossoms are to be preferred to those which have brilliant leaves; and if they are discreetly selected the succession of bloom may be kept up all summer. And then, if American plants are relied upon, autumn will bring a magnificent diversity of its own. What bright hued plant can be named, as a factor toward variety in the pleasure-ground, which compares with the Dogwood—covered in spring with sheets of white blossoms, showing a beautiful spread of peculiar green in midsummer, in autumn turning to a vivid crimson, and keeping late into the winter its burden of scarlet berries? What foreign shrubs can give us the changeful effects which may be secured by a well-arranged bed of Sumachs of different kinds—showing diverse tints of green, ornamented in summer with bold panicles which are pale green, rosy, bright red, or deep brown in color, and in autumn becoming a glowing mass of ruddy foliage? What exotic has leaves more beautiful than the shining Tupelo's, or turns suddenly like the Tupelo to a gorgeous red, which lasts for many days or weeks? What task presented by any collection of alien trees and shrubs could be as interesting to the intelligent planter as the task of so adorning his grounds with American trees and shrubs that, after their varied kinds of spring and summer beauty have been enjoyed, a new and wonderful autumn symphony will develop, shading from the pale yellow of the Beech to the vivid yellows and reds of the different Maples, the scarlet of certain Oaks, and the dusky purple of the Ash, and emphasized by the still more brilliant reds of Tupelos, Sumachs, and Dogwoods? The very mention of a place adequately treated with this aim in view makes our customary arrays of yellow and striped and blotched and brownish garden plants—monotonously alike from year's end to end—seem by comparison, unintelligent, inartistic, and tiresome.

### The Wayland Group of Plums.

IN an article in last week's issue of GARDEN AND FOREST I called attention to the continuity of the series of intergradations between the Americana and the Chicasaw Plums and said that the series might be roughly marked by three types, the Miner, the Wild Goose and the Schley or Clifford. It was also noted that another group, standing somewhat aside from this series, might, for the present at least, be regarded as belonging among the Hortulana Plums, and that this group is comparatively distinct and very interesting. This I have designated as the Wayland group\* from one of its best types, the Wayland Plum. Golden Beauty is also a good type of this group, and is well known in the southern states, though not northward. Moreman is the commonest variety of the group in the northern states, but is not well known in the

south, and is not quite so good an exponent of the characters which mark this group. After considerable deliberation I think that Wayland is the best and most convenient group name for these varieties.

Of course, this group is not free from puzzling forms which show equivocal characters, apparently borrowed from the Chicasaws, Americanas and other groups; but on the whole it is much better marked than the Miner or Wild Goose sections, which have for several years been thought worthy of recognition. The varieties are characterized by straight, slender, dark-colored twigs, very large luxuriant foliage, broad leaves, which are often pubescent on the larger veins beneath, and which have from two to six glands on the petioles; axillary buds often triple; blossoms and fruit very late, mostly after Miner; fruit spherical, or nearly so, red or yellow, with many small dots, thin-skinned and of fine quality.

Several varieties of this group are already widely distributed in cultivation. Others of considerable promise have been recently introduced. Those which I have had the opportunity to examine, and which seem to belong with Wayland rather than in any other group, are Columbia, Crimson Beauty, Cumberland, Garfield, Golden Beauty, Kanawha, Leptune, Missouri Apricot, Moreman, Nimon, Reed, Sucker State, Wayland and Worldbeater. Mr. T. V. Munson, in correspondence, mentions another variety, Erby's September, growing in his grounds, which apparently belongs with those named here.

Of these varieties, Cumberland, Golden Beauty, Kanawha, Leptune, Reed and Wayland best show the distinctive foliage and tree characters which separate them from adjoining types. These are all good Plums from the planter's standpoint. All of them are very ornamental. Reed is one of the most beautiful trees of its size I ever saw.

These varieties have usually been put in the Wild Goose class, though Bailey, who has done most of the work in the classification of native Plums, puts Leptune, one of the best marked varieties, into the Miner group, and President Berckmans, who introduced Kanawha, says "this is beyond question a form of *Prunus Americana*." The whole group has also been roughly referred to *P. glandulosa*, Torr. & Gray, but this is evidently a mistake. Mr. T. V. Munson has given this question serious study, and has concluded that all these varieties are derived from *P. rivularis*, Scheele. This is a somewhat startling decision, and extremely important if true. The facts are, however, first, that we are yet too poorly acquainted with this species to make critical comparisons; second, that Scheele's description, made at second hand from Lindheimer's specimens, is not sufficiently precise to preclude mistakes; third, that the description,\* what there is of it, fails, in important particulars, to fit the varieties in question; and fourth, that many of these varieties have originated in localities where it is almost impossible to believe that *P. rivularis* could be growing.

To particularize further, the National Herbarium† contains only the following specimens: Those of Lindheimer, collected in western Texas in 1846; one by Hall, from Dallas; two by Wolf, collected in Illinois in 1875 and very possibly cultivated specimens; and one of doubtful authenticity by Thomas Bassler, from Manhattan, Kansas. Other herbaria seem to have no better representation of the species, and this could hardly be the case were it so common

\* Since this description is inaccessible to many students, it will be well to transcribe it here:

*Prunus rivularis*, Scheele, *Linnaea*, 21, 594. Frutex 3-6 pedalis; rami angulati glabri nitidi cinerei verruculosi, verrucæ parvæ confertæ. Petioli glandulosi canaliculati puberuli. Folia ovate-oblonga acuminata inæqualiter serrulata, basi glandulosa, subtus sporæ pubescentia, supra glabra, serraturæ callosæ confertæ. Umbellæ laterales sessiles, subbifurcæ. Squamæ gemmæ floriferæ aphyllæ. Pedunculati glabri elongati subglandulosi, petiololum æquantes. Flores . . . Drupa rubra globosa glabra nitida acida.

"Gesellschaftlich an Bachrändern, seltener aber jedesmal in Menge zusammenstehenden auf Hügeln. Strauch 3-6' hoch, Frucht kugelig, hell-roth, angenehm säuerlich, von der Grösse einer Kirsche bis zu der einer Mirabelle, ½-1" dick. Die Tawakong-Indianer sollen die Frucht, mit Honig gekocht, sehr lieben. Die Texaner nennen sie 'Tawakong plum'." Lindheimer.

Gehört zur Rotte *Eucerasus*, Torr. & Gray.  
Seltener stehen die Blumen einzeln.

† The specimens in the National Herbarium were kindly examined for me by Mr. Lyster H. Dewey.

\* Vermont Experiment Station, 10th Report, p. 103.

and so widely distributed as to furnish the well-known cultivated varieties mentioned above. The varieties in question differ from Scheele's description in having single straight trunks, in being from fifteen to twenty feet high, instead of from three to six feet, and in having often three flowers to each fascicle, instead of one or two. The distribution of the species is given by Coulter\* as "not uncommon on the Colorado and its tributaries, and extending to the upper Guadalupe and the Leona," and the specimens referred to above give no important evidence of its occurrence this side of western Texas. In comparison with this distribution the origin of the cultivated varieties should be carefully considered. As far as known their sources are as follows: Cumberland, Tennessee; Garfield, Ohio; Golden Beauty, south-west Texas; Kanawha, Fairview, Kentucky; Leptune, Arkansas; Missouri Apricot, Missouri; Moreman, Kentucky; Sucker State, Illinois; Wayland, Cadiz, Kentucky.

The evidence of this list is quite contrary to the supposition of a *Prunus rivularis* parentage for the varieties named; but, on the other hand, must be regarded as decidedly favorable to their classification in the pseudo-species, *P. hortulana*.

It seems to me important that this group of Plums should be understood separately, and that its relationships should be worked out as speedily and as accurately as possible; and while the evidence here reviewed leads me to reject the hypothesis of their derivation from *Prunus rivularis*, that species seems to be a promising one, and we would do well not to lose sight of it too soon.

#### What Can be Done in Nine Years.

MANY persons think it is useless to plant trees because so many years will be required for their growth that the planter will not live to sit under their shade, and can never enjoy the fruit of his labors. This is clearly a mistake. From personal experience on a most unpromising piece of ground, I am prepared to say that three years' work will produce an encouraging effect almost anywhere if one goes about it in the right way; that in five years trees will be well enough along to be ornamental, while in ten years one may have a really beautiful place if it is properly planted to begin with.

An account of our inexperienced beginnings at Overlea was published in GARDEN AND FOREST six years ago (see vol. iv.), and to those who were interested in that story this account will not be without a certain value, as it will show how a little place can be rescued from total neglect and desolation and turned from an eyesore into an ornament of the village in a few short years. One decade counts for little in a life, and it must be remembered that not half of that time was required here to produce valuable and effective results, even with imperfect knowledge and very moderate expense. We began on our abandoned farm by planting a screen of Willows along the straight street which separates it from the salt marsh of which it was originally a part. These Willows, it may be remembered, were driven down as stakes, without a leaf or branch, along the boundary, and set as closely as possible in a row. Some of these have now reached the height of forty-five feet, and a large one within the line, in a particularly propitious situation where it had room to spread, left, when it was felled last year, a butt considerably over two feet in diameter. All have not grown equally fast, for some of them had to be moved, and others, being set along the street made by filling in across the salt-marshes, had a very stony foundation as well as an occasional dose of salt-water from a high tide, and grew feebly. These, however, exist just where we desire to have them as a hedge, and their tops are kept down that we may view the meadow on the other side, so that their lack of vigor is an advantage. By vigorous pruning they have assumed a round bushy form, thick at

the base, and the road outside is completely hidden from sight.

A White Willow, already of good size when set out in 1888 near the house for immediate shade, has spread widely from having been polled in the beginning, but is ten feet shorter than the trees which have grown from stakes. A Golden Osier carried in my hand from a neighbor's house in 1889, and transplanted twice, now measures thirty-nine feet in height, having run up a long leader, always much bent over by the prevailing south-west winds of this region. Both these trees are set upon a sandy knoll with no moisture, whereas the fine specimen which was cut down had its roots in the fresh meadow, where it was always well watered and supplied with good soil.

The Willow at the south-west corner of the house we always intended to remove after a few years, to leave room for a Maple beyond it. But though the branches of the two now touch, it is so pleasant and important a neighbor that we have not yet found resolution to take it away. The fact is that the planting of nurses for trees results in subsequent pangs, for by the time the nurse ought to come down it has grown dear and necessary, and though it is injuring its charge, the charge is still incompetent to take its place. Then one is sure to weakly succumb and temporize after our feeble human fashion, preferring, as we do, present comfort to future good. Nobody but the born philosopher has the courage "*de se tourmenter pendant la vie pour qu'on parle de lui quand il soit mort*." Strive as we may, our philosophy is ever tempered with weak-hearted relenting toward those branches which have first shaded our bare walls, even though we have sense enough to be ashamed of it. To cut down a tree and sit in the sun for two or three years until another grows large enough to take its place, is more than we can do yet, but no doubt we shall come to it.

Next to the Willows the Maples are our tallest trees, and the crowning glory of the front of the grounds is a symmetrical White Cut-leaved Maple, which, but an eight-foot feather-duster in the summer of 1888, is now more than thirty-five feet high, with a spread of nearly thirty feet. This tree grows on the gravelly knoll on which the house stands, its only advantage being that it had a wide, deep hole dug for it, into which seven loads of loam were dumped when it was planted. Such a tree set out in congenial soil would probably be much larger, but my object is not to show what can be done with favorable conditions, but with those which at the outset seemed most unpromising. The result goes to prove that if a good bed is made for a tree at the start, and plenty of water and top-dressing are supplied for two or three years, it will afterward be in condition to get its own living, even from such poor pickings as a gravel bank affords; and that no one should hesitate on account of seemingly impossible soil to give a tree a chance by a slight expenditure in the first place, to show its powers of growth and endurance. The White Maple flourishes here, in glacial debris, with a number of other trees within thirty feet of it, and is quick of growth and particularly agreeable in outline. Its lower branches have a graceful downward sweep to the ground, with the tips mounting up again in a curve; the foliage is a cheerful light green of very open and airy character, so that the sunlight is not excluded from the turf below. The one I speak of was eighteen inches in circumference two feet from the ground at the time it was transplanted, and now measures three feet around in the same place.

Two good-sized Norway Maples, transplanted in January, 1888, are now as tall as the ridge-pole of the house. They were too severely cut back at first, our knowledge of a tree's necessities being at that time very limited, and consequently they made too many branches and have to be thinned out every June, the best month for pruning Maples. The largest of these trees is about three feet in circumference at the base, with a shock head, very thick and round, but not particularly graceful, and is about twenty-five feet high. Its neighbor is much more beautiful in form

\* *Botany of Western Texas, Coll.: U. S. Nat. Herb., vol. ii., p. 102.*

and is a little taller, while a third of the same species planted sixteen months later, when much smaller than the others, overtops them both, though it has not so great lateral extent. This goes to prove what the authorities state, that in the long run small transplanted trees outgrow large ones. The offset to this fact is that the latter give you more shade immediately, while you are waiting for their younger neighbors to attain their height.

So far as our observation goes the larger the tree transplanted the more stationary it remains, if it remains at all, which is most unlikely. A few years ago a man from the west came to this town and offered for a large price, ranging from forty to a hundred dollars each, to move trees of any size and warrant them to live. A machine was used to lift them after the roots had been cut off too near the trunk. The great Oaks and Elms moved for some of our neighbors, while ornamental for a couple of years then began to die. In a few instances, where the trees were planted in excellent soil and had continuous care in the way of watering and top-dressing, the experiment was justified, though these have merely held their own, and most of the trees were lost.

We planted a number of acorns of English Oaks eight years ago, and the tallest trees from these are about twenty feet high, and are vigorous and beautiful. They have not had a very good chance to show what they could do, for the swale in which they grow is sandy from the wash of the road, and very tightly packed and grassy, as it has not been disturbed for many years. Into the same dry, unfavorable soil we transplanted six young Chestnuts in 1888, but an insect dwarfs their early spring growth every year, and they do not like the salt east winds to which they are exposed. They are well rooted and healthy enough, but make slow progress skyward, and are not yet twenty-five feet high. Some Chestnut seedlings planted later promise to do better than the saplings, and are fast overtaking them, though rooted in the cold gravelly north side of the hill. Here, too, young Walnuts and Oaks are beginning to show among the Pines, and Gray Birches flourish in a race with the evergreens.

In one corner of the narrow front lawn which separates us by about ninety feet from the village street, flourishes a clump of five different kinds of Birches, and these, born to live on little, content themselves cheerfully with the scanty living sucked from the thin soil in which they grow. Of these five the common European Birch, *Betula alba*, with its white stem gleaming through the clustering curly branches which closely encircle it, is the tallest and most vigorous, and with its bright small leaves and numerous tassels is a pleasing feature in the group. Near it a Cut-leaved form of this Birch grows tall and spindling, with sparse foliage, casting dancing shadows on the grass. Its stem is of smooth and dazzling whiteness, and its pointed, deeply indented leaves make a delicate tracery against the sky. In the foreground stands a Paper Birch, *B. papyrifera*, from Maine, with large shining leaves. Its bark has a warmer tone than that of the European Birches, and is flecked with dark spots. It grows more slowly, too, probably because it is only a scion which came up from the root of an apparently dead sapling that did not survive its first winter, and therefore has not the vigor of an original stem. It is dear to us, for it brings with it a suggestion of the northern woods where it grew, where its stately ancestors still furnish canoes to the Passamaquoddy Indians, and we watch with interest the changing hues of its rolling bark, and enjoy its gradual alteration from a dark sapling to a white trunk with the familiar dark gray diversifications. A young Yellow Birch, *B. lutea*, stands in the neighborhood, but whether from poor soil or its own habit has never advanced. Behind the group, and nearest the street, is a good-sized native Gray Birch, *B. populifolia*, which was a wayside bush preserved when we graded the knoll. This and a tiny White Ash, *Fraxinus Americana*, were the only green things upon the lawn when we began, and now the latter has grown into a stout, wide-spreading

tree which robs everything in its neighborhood. While not so rapid a grower as some of the other trees, it bids fair to survive and overtop them all before many years. It struggles now with a transplanted Black Oak for mastery of the situation.

The greatest surprise of all on this small, crowded lawn is *Catalpa speciosa*, whose tropical foliage and great spires of enchanting bloom would seem to require far more sustaining food than it can possibly find on this slope. In a dry season it has a trick of dropping many of its first leaves when the second growth begins, but this year it has shed but few, owing to frequent rains. It spreads its wide arms and flutters its huge leaves, and is altogether the most foreign looking tree in the collection. Its top blew off in a gale three years ago, and this seemed to add to its spread. If it would only not wait until the middle of June to develop its leaves and begin to drop them early in September, no tree would be a more splendid inheritor of the earth. It is really a joy to behold in its perfection, it is so luxuriant and brave in its golden-green array. A photograph of the house taken in 1888 shows it standing up hard and bare against the sky. No vines nor shrubs link the foundations to the grassy terrace. Little sticks with plummy tops stand about at what seem wide and hopeless intervals, a few stems indicate the presence of future creepers, and the gravelled driveways look enormously out of proportion to the turfed spaces. The whole aspect was then hopelessly dreary and bleak but for the fine stretch of picturesque meadow.

A photograph taken in 1891 shows a pretty little group of trees already well started about the dwelling, and one made for me by a friend this month from the same point of view, only reveals the north gable end of the building which has been left unshaded for the sake of the prospect from its windows. All the rest of the house is hidden by foliage, draped in vines, or buried in shrubbery, so that only the chimneys are seen peering up amid the nodding tops of a grove of well-grown trees, which by another year will conceal even these altogether.

All this is the result of only nine years' growth, and goes to prove how well the careful planter is recompensed for his efforts.

Hingham, Mass.

Mary C Robbins.

## Plant Notes.

### Romneya Coulteri.

FEW California plants are better known by repute to growers of hardy plants than *Romneya Coulteri*. Unfortunately, few in the east have had the opportunity to establish it, owing to the scarcity of proper material. The seeds offered by the dealers will hardly germinate in less than a year, and there are many contingencies from the planting of such seeds until their growth into plants strong enough to produce flowers. Roots have been only occasionally offered, mostly weak bits which have soon joined the majority, and the desire to grow this Poppywort has probably mostly abated. This is unfortunate, for it is a plant of most distinct habit, with beautiful flowers, and in my experience not difficult to establish and grow in the open in this latitude. Mr. Sturtevant kindly sent me some strong roots four years ago which were planted in a warm border at the south side of the house. During the three winters to which they have been exposed they have been protected simply by a mound of earth about a foot high and topped with ashes. This unsightly device is a very useful one for plants of which one is doubtful, or which it is desired to protect from quick thawing and freezing, the bane of hardy-plant culture in this changeable climate. A strong root has produced during these seasons a varying number of stems, this year twenty, although this number has been exceeded previously. The plants would spread by creeping roots if allowed to do so. The growth of the stems is about five feet, and they reach this length in May. They are always somewhat prostrate, the strongest growing only partly erect. As the smooth, pithy stems are brittle, the plant should

have protection from the wind. The leaves are persistent and lose their vitality with the storms in early winter, and as they show no signs of ripening previously it is fair to suppose that in a milder climate they would be of more than annual duration.

Though growing well each season it has not flowered with me until this year; the failure is evidently due to the production of too much thin wood. The flowering shoots this year are fewer and thicker and the plant evidently requires judicious thinning, and perhaps some fertilizer. The flowers are produced at the top of the stems, there being a crown-bud and two or three terminals on short, leafy stems. The pure white flowers, with six much-crimped petals, are from five to six inches across and have a hemispherical mass of golden stamens surrounding the ovary. The illustration on this page scarcely does justice to its beauty of form, for its petals are often contorted, and being of delicate texture and swayed by each breath of air there is always a beautiful play of life and

distinct character of this new break appears in the flowers, which are in the usual colorings and single, but sometimes attached to all the petals, and sometimes to only either the inner or outer pair. A growth springs from the lower section, but not from the base of the petals. As this growth becomes free it takes on crested forms which are unique, being very irregular and decidedly attractive. The centres of the Single Tuberous Begonias have always been quite bald, or rather unattractive, and this new strain is a gain in beauty as well as an extremely interesting example of a floral metamorphosis, further phases of which may be expected. A single flower with growth of similar character was shown in an exhibition in the Grand Central Palace, in this city, some five years ago, by the Oasis Nursery Company, which, of course, is an illustration of the familiar fact that plant sports usually occur in several places at the same time. I have been expecting and hoping for some years that some one would select or secure a strain of Tuberous Begonias with brilliant leaves. It appears to be within the

Fig. 46.—A Flower of *Romneya Coulteri*.—See page 352.

light over it as the illumination changes. The petals seem peculiarly sensitive to light, opening wide in full sunlight and partly folding under duller rays. As each flower lasts three days this sensitiveness of the petal is useful, for late in the afternoon two of the inner petals fold up over the stamens and protect the pollen from dew or dampness. Though this plant does not flower profusely under ordinary conditions, it seems to be a good subject for the attentions of a deft cultivator, for there springs from each leaf-axil a short leafy stem which apparently might be converted into a flowering shoot with proper cultural skill.

**CRESTED BEGONIAS.**—Under the somewhat cumbersome, but descriptive name of *Begonia grandiflora erecta cristata*, Messrs. Vilmorin introduced last year a new type of tuberous Begonias. This new strain is said to have been obtained or selected by Messrs. Vallerand Freres, and is so far fixed that a fair proportion of seedlings is said to come true. The tubers and foliage are of the ordinary type of tuberous Begonias, now familiar to all gardeners. The

possibilities, for a plant here some years ago gave a promise of brilliant foliage by producing a stem with leaves of the richest colorings. Unfortunately tubers were very plentiful at that time, and the promising one was lost in the rabble.

## Cultural Department.

### Hybridizing Sarracenias.

**O**WING to their odd shapes, and in some cases their beautifully marked leaves, the Sarracenias are much prized in European collections; indeed, more highly than they are here in their native country. During recent years some remarkably handsome hybrids have been raised, especially from the dwarf-growing species. The leaves of all the species are hollow; some resemble pitchers and others are trumpet-shaped. Five of the species are protected by a hood-like covering on the top; *S. purpurea* is unprotected. All of the species ensnare insects by an arrangement of hairs on the

inner portion of the tube. On the part nearest the orifice of the tube even the house-fly cannot obtain a foothold. The lower portion is covered with a multitude of hairs barely visible to the naked eye, and their ends are directed toward the bottom of the cavity. When an insect is once inside the chances are greatly against it regaining its liberty.

The flowers are quite as curiously formed as the leaves. The style expands at the summit into a structure exactly resembling an umbrella, which is composed of five divisions, and each division terminates with a small hooked stigma. The long petals, five in number, protrude from between the divisions of the style. The stamens are quite numerous. There are six species, all native of the Atlantic states. Five of these are found only south of Virginia; the other species, *Sarracenia purpurea*, ranges from Florida to the most northerly point in the New England states. *S. psittacina* is the least attractive of those, having small pitchers shaped like the head of a parrot. *S. variolaris* grows about ten inches high; the hood is more perfectly developed than in any of the other species. On the top of this hood are whitish, almost transparent, spots, the purpose of which has not been made clear. The color of the flower is yellow. The only other yellow-flowered species is *S. flava*, the most common of the southern species. It grows to a height of from one to three feet. The prevailing color is greenish yellow, with beautiful reddish brown markings on the under part of the hood and a little way down the tube. *S. Drummondii*, from a horticultural point of view, is the most attractive species. Like *S. flava*, it is an erect-growing species. Its beauty lies in the hood and the upper portion of the tube, which are white veined with dark purple, and a well-grown plant never fails to excite admiration. It grows in the almost impenetrable swamps of Florida. *S. rubra* is a low-growing species with numerous narrow pitchers. The flowers are very sweet-scented and their odor somewhat resembles that of the common English Violet. The common or best-known species is *S. purpurea*; like those of *S. psittacina*, the pitchers are prostrate on the ground.

Among the numerous hybrid forms there are several with very large pitchers, such as *Sarracenia Chelsonii*, a hybrid between *S. rubra* and *S. purpurea*. This species colors up well, but is inferior in markings to *S. purpurea* as it is found growing in favorable situations about Wilmington, North Carolina. A cross between *S. variolaris* and *S. purpurea*, named *S. Swaniana*, has the broad form of the latter, while the light markings of *S. variolaris* are intensified. One of the handsomest hybrids is *S. Formosa*, between *S. psittacina* and *S. variolaris*. The form is nearly intermediate and the rich markings characteristic of *S. variolaris* are seen all over the upper part of the pitcher. All the species of *Sarracenia* intercross very readily under cultivation, and not a few natural hybrids have been found in the native wilds of these plants. If there are several plants of each species in a collection and each comes into bloom at the same time, which is an easy matter to accomplish by putting the backward ones into a little heat, there is no difficulty in raising an endless variety of hybrids. If some of the best of the hybrid forms already in cultivation were used as pollen parents the resulting seedlings would probably develop something entirely new. Two or three years ago I had the pleasure of raising many hundreds of seedlings, using all of the species as seed-bearers, and some of them along with already existing hybrids as pollen parents. So readily did they intercross that not a single flower failed to set seed. Of the hundreds of plants grown from the seed those having *S. Drummondii* or *S. flava* blood in them, no matter what they were crossed with, were always much inferior to the parents both in form and color. One set between *S. Drummondii* and *S. crispata*, the former being the seed-bearer, has more dark purple than there is in *S. Drummondii*. The most satisfactory results were obtained by using *S. psittacina* as a seed-bearer, taking the pollen of *S. variolaris* or *S. purpurea*, or even hybrids of these species. *S. variolaris* is also a good species to select as a seed-bearer. *S. purpurea* crossed with any of the species excepting *S. Drummondii* or *S. flava* gives some pleasing forms.

Although the raising of new varieties of *Sarracenia* through hybridizing is an easy matter, no small details should be neglected, or good results will not be secured. It is safest to keep the seed-bearing plants by themselves, and when the flowers are unfolding their petals, or just before the anthers shed their pollen, the stamens should be removed with a small pair of sharply-pointed scissors. The pollen to be used is in excellent condition when it falls on the concave surface of the expanded style. A little should be taken on the point of a camel's-hair brush, just enough to cover the five stigmas which are situated on the under parts of the extremities of the

divisions of the umbrella-shaped style. To prevent confusion a label should be tied to each fertilized flower, containing the names of the parents, the seed-bearer first. The seed will ripen in time to sow and have the seedlings about an inch and a half high before the approach of winter. A good mixture in which to sow them may be made up of two parts chopped sphagnum and one part charcoal, rough-grained sand and broken pots small enough to go through a quarter-inch sieve. This should be mixed thoroughly, firmly pressed, and the seeds covered but slightly. A pane of glass should be placed over the top of the seed-pans, and these should be stood in the shady part of a cool house. The two seed-leaves are about half an inch in length and quite narrow; the first true leaf reveals the genus to which they belong. At this stage they may be pricked off around the edge of a three-inch pot, putting eight or ten in a pot, in the soil already described, and they will pass the winter safely in these pots. When they begin to grow in spring they should be singled out into two-inch pots, using a little fibrous peat with the soil mixture.

Botanic Garden, Washington, D. C.

G. W. Oliver.

### Seasonable Notes.

**L**ASIANDRA MACRANTHUM, perhaps better known under its old name of *Pleroma macranthum*, is a welcome addition to the few greenhouse plants in bloom at this season. The flowers, which are of a beautiful deep violet-purple color, are freely produced at the ends of the shoots in branchlets, and although the flowers only last about twenty-four hours, new ones open every day, and the flowering season continues through several weeks. From cuttings inserted in April we have now nice, bushy plants, in six-inch pots, but to grow this plant most successfully it requires to be kept two or three years and trained on a wall or tied to some wires on the side of a cool house. With a fair amount of root-space under such conditions it blooms for a long time and commands attention from all who see it. *Lasiandras* are of the easiest possible cultivation. They are not seen in many places, probably owing to the short-lived nature of their flowers and the fact that they have no value for cutting.

*Caryopteris mastacanthus*, which has been quite extensively advertised as a novelty during the last year, is really an old plant, having been introduced from China as long ago as 1844. I remember seeing the plant grow freely on a warm border in a garden near the Scotch border twenty years ago. It was then called *Mastacanthus Sinensis*. It made quite a neat little bush, but was not held in any particular esteem, and did not prove reliably hardy there, but a scattering of broken fern overhead and a mulching of manure at the root carried it through the winter safely. I saw well-grown small bushes of it last summer in the south of England, where it was said to be quite hardy. It is only occasionally seen even in England. When exhibited by Mr. Manning, of Reading, last year in Boston, it won a silver medal. It attracted much notice there and was described in some of the papers as a new introduction from China and called *Blue Spiræa*. A more correct name would be *Blue Verbena*, belonging as it does to the order of *Verbenaceæ*. I am unable to state whether *C. mastacanthus* is hardy in this climate, and it is probably not. It germinates freely, and from seeds sown about March 15th we now have good plants in bloom in six-inch pots. The flowers and plants are lavender-blue. In catalogues they are described as azure-blue and rich violet. The plant as we knew it two decades ago bore flowers of the lighter shade. There is a pure white form of *Caryopteris* which I have not yet found, but which is said to be an excellent companion to the blue one.

*Chrysanthemum Golden Fleece* is useful grown in a row by itself, or dotted here and there, as we grow it, in the perennial beds. Yellow flowers are perhaps too much in evidence at this season, with so many *Helianthus*, *Heliopsis*, *Rudbeckias*, *Coreopsis*, etc., but on account of its height (about two feet) and its persistent blooming qualities, this *Chrysanthemum* is worthy of a place in every flower border. It begins to flower with us about July 20th, and continues until cut down by frost. It proved perfectly hardy here during the past two winters, only a few half-decayed leaves being scattered over each clump. The flowers are extremely useful for cutting.

Taunton, Mass.

W. N. Craig.

### Work of the Season.

**T**HE replanting of Carnations must now be attended to promptly, and the weight of opinion is in favor of having them under glass by the first or second week of September.

The plants are thus much more under control than if the operation is postponed. Care in lifting the plants is necessary to keep the roots entire, but a large ball of earth does not seem to be essential. Indeed, some growers go to the opposite extreme and shake off all the soil from the roots before replanting, and they claim that a better start is gained by this plan. When this is done rather more care is required in frequent syringing and ventilation until the plants become established in their new quarters. After the Carnations have begun to grow again but little syringing is needful, and during the dull and damp days of fall and winter no water from overhead is the safest rule. About five to six inches of soil on the bench is sufficient for Carnations, but this should be of good quality. Well-rotted sod is the best material, and of fertilizers, stable manure, wood-ashes and bone-dust are among the most satisfactory, and should be used in such proportions as are best adapted to the particular soil used.

Improved methods of staking and tying Carnations are still being discussed by the experts, many of whom have devised wire stakes of special form for this purpose, so as to support the plant neatly and admit plenty of light and air.

The frequent and unusually heavy summer rains in the eastern states have proved quite disastrous to Carnation-growers in some sections. One instance noted recently is that of a florist in Connecticut who planted out 16,000 Carnations in the spring, and at this time has only about 3,000 live plants, the remainder having been destroyed by wet weather.

Cyclamens that have been growing in frames during the summer will also be safer in the greenhouse from this time onward, for the damp and chilly nights of early autumn are likely to injure these useful plants. While in growth Cyclamens should never become very dry, yet an overplus of water also checks them.

Acacias, Azaleas and other hard-wooded greenhouse plants may remain out-of-doors for some time yet without injury; in fact, the early housing of plants of this character may induce a secondary growth, and to some extent interfere with their spring flowering.

Poinsettias should be brought under cover, for too much rain and chilly nights cause loss of roots, and consequently of the lower leaves, and frequently change a promising lot of plants into the unsightly specimens so often seen.

*Lilium longiflorum* and *L. Harrisii* should be left out in frames for the present unless they are intended for very early forcing. The 1st of October is a good time to transfer them to the greenhouse, and in favorable seasons I have sometimes left them out until November 1st, as a stronger root-growth is thus gained. The tops are in this way kept short-jointed and sturdy, and no staking is required unless the plants are packed for shipment.

Young Begonias for winter flowering, of which the *Incarnata* varieties, those of the *Socotrana* section (for example, *B. Gloire de Sceaux* and *B. John Heal*) and *B. Digswelliana* are among the most useful, may need another shift to give sufficient root-space to carry them through the season. Six-inch pots are a convenient size to use for well-grown and showy plants for conservatory decoration.

Show Pelargoniums are also admirable for the conservatory in spring and early summer, and while these plants may be kept outdoors to advantage during the summer months, it is not advisable to leave them out late. The heavy rains and cool nights affect these plants unfavorably, as they require but little water during fall and winter. A few strong young clumps of *Arundo donax* now lifted from the garden and potted up in large pots or tubs, will be found a useful addition to the conservatory plants during the winter; not only for their graceful habit and beauty of foliage, but the shoots may be cut and used effectively among cut flowers for filling large vases.

Holmesburg, Pa.

W. H. Taplin.

### Chrysanthemums and Rex Begonias.

FROM this time onward will be a critical period for Chrysanthemums. Plants in pots have now filled them with roots, and to keep the plants in good condition they must be fed, and judgment and experience are necessary in the proper application of nourishment. The misuse of a fertilizer may spoil a season's work, not taking into account the worry and disappointment. I know how easy it is to make mistakes and also the danger of repeating the error. The grower must feel his way, especially with a stimulant of whose strength he is uncertain. Drainage from the stable is safe, diluted to one-eighth strength, or until it has the color of weak tea. An application once each week is sufficient for the first month, but the cultivator must be guided by the foliage area. Change of diet is

good for plants as well as for men, and at intervals sheep-manure water may be applied, and occasionally soot-water. These latter mixtures we make by putting the materials in a coarse bag and letting the strength leach through. If worms are troublesome, a little lime-water will drive them away and benefit the plants as well. As the season advances we may try a little of Albert's Horticultural Manure. Its action is quick for benefit as well as injury. A pound to fifty gallons of water is full strength, and a weaker solution would be safer. This manure gives a fine color to the foliage.

Rex Begonias are now in full beauty. While they are more or less evergreen they are benefited by a season of rest, but it is surprising how much hardship they will endure so long as the atmospheric conditions are suitable. Seedlings and broken parts of leaves frequently take root in gravel or under the greenhouse benches. A favorite place for them is the walls of artistic ferneries, with little else than decayed moss and charcoal to root in. Rex Begonias are an attractive feature in the grotto on the estate of the late F. L. Ames, at North Easton. On the Simpson place, at Saxonville, they are used in the same way, and their large glistening, often iridescent, obliquely cordate leaves stand in bold relief from the walls. Upon remarking to a friend how well they did on the dark side of his tropical plant house, and that the close atmosphere of such a place suited them, he directed me to the greenhouses belonging to Mr. J. D. Little, of Brookline, Massachusetts, and I there found the handsomest plants I have ever seen, growing under very different conditions. The plants were in an old-fashioned lean-to with front ventilators and heavy eaves, under the shade of which they were growing.

The typical Rex Begonia is characterized by a surface-growing rhizome, all the leaves being radical. Besides the type the collection includes a large number of hybrids, which, while maintaining the zonal character of the type, are more shrubby in habit, and often have deeply cut foliage. It is difficult to trace the parentage of many of these hybrids, although the blood of *B. diadema* and *B. Olbia* is plainly seen in many of them.

A description of some of the most striking varieties must include *Lesondsii*, dark and light green with silver spots and margin; *Magnifica*, deep bronze, with lighter green spots; *Mrs. E. Bonner*, hybrid Rex, shrubby, the leaves very much divided, silvery, with dark centre; *Madame Treive*, hybrid Rex, dark and light green shadings, with silver band; *Fen-delet*, dark green, silver spotted, the raised midribs stained with red; *Desfontaine*, finely spotted, with band of silver, reddish hue; *Annie Dorner*, hybrid Rex, cut-leaved, dark and light green, spotted slightly; *Bertha McGreggor*, hybrid Rex, dark centre, with bands of silver and bronze; *Mrs. Bonner*, long-pointed, silvery green, dark edge, very fine. There are many other fine varieties, but these are the best.

Wellesley, Mass.

T. D. Hatfield.

### Antirrhinums.

THIS genus, though not extensive, contains several species all more or less hardy and mostly herbaceous. The majority are mainly useful for rock-work, but probably the best of all is the old-fashioned Snapdragon, *Antirrhinum majus*, and its numerous varieties. These easily lead all the other species in variation and brilliancy of coloring. Names have been given to some of the more distinct varieties, but few growers take the trouble of keeping them true to name.

These plants are often classed among hardy herbaceous plants, but I have never found them quite hardy in this section. When it is desirable to perpetuate some of the most distinct varieties I find it necessary to strike cuttings in September and winter them in cold frames, planting them out when the ground has become dry enough to work in spring. These plants bloom much earlier than those grown from seed unless the seed is sown in fall and the seedlings wintered in the same way. Under favorable conditions the plants usually begin to flower in May. They are useful as bedding plants and in the herbaceous border.

The readiest and most common method of obtaining plants is from seed, and one packet selected from a good strain will give all the variety desired. If sown in the greenhouse in March and grown with care they will flower by July and continue throughout the summer season. Though of the easiest culture, they will repay a little extra attention. Too often they are crowded together and receive little or no attention, with the result that their true character is not brought out and much of their beauty is lost. They should be planted in well-enriched ground and sufficient space allowed for the development of each plant, with proper attention to staking and tying. The handsome flower-spikes will fully repay this care.

Tarrytown, N. Y.

William Scott.

*Carex Japonica*—This pretty little Grass, with yellow and green striped foliage, proves useful in many ways, and small plants in four-inch pots, alternated along the outside of a table with plants of *Isolepis gracilis*, make a pretty arrangement. It is also attractive with Ferns in artistic basket-work, and for Fern cases. A few plants out-of-doors have stood the sun well, and it evidently will prove a good bedding-plant.

*Clematis tubulosa*—This shrubby plant is one of the most striking features in the border at this season. It forms a neat, low, rounded bush just now, and is covered with small deep blue flowers. It is especially suitable for planting on hillsides and in a low shrubbery.

*Kelway's Delphinium, Princess of Wales.*—This is the first white perennial Larkspur I remember ever to have seen. Only the few deformed petals which form the shield for the stamens are dark-colored. The sepals are the showy part of the flower, and are often mistaken for petals.

*Violas, or Tufted Pansies.*—A bed of these yellow and blue flowered plants has interested many visitors, who mistake them for Pansies. But while the flowers of Pansies grow smaller as summer advances, *Violas*, which are summer-blooming, are then at their best. They are easily raised from seed sown in spring.

Wellesley, Mass.

## Correspondence.

### Notes from West Virginia.

To the Editor of GARDEN AND FOREST :

Sir,—Varieties of *Hibiscus Syriacus*, commonly called *Althæas*, are freely planted in this neighborhood. Although rather stiff-looking shrubs, they are useful at this season of the year, for they are in bloom throughout several weeks of late summer and early autumn, and, with the exception of some *Hydrangeas* and a few other plants, are the only shrubs now in flower. For want of other material, we often use *Altheas* for cut flowers for the house and also for the decoration of the little church in the village near which Rose Brake is situated. Generous branches cut from the shrubs are quite effective in large jars and vases. A recent arrangement of these flowers had several attractive features which I would like to describe. Jars for corners and fire-places were filled with sprays of the pale rose-colored single *Althæas*; others with the pure white variety which has deep maroon-red centres. Double and semi-double flesh and peach blossom-colored *Althæas* were also used in masses, each variety by itself. In smaller vases the light-toned and white kinds were combined with foliage of a Japanese *Snowball* and many tall heads of *Wild Carrot* to soften and give variety to the effect. The particular *Snowball* used is one that differs from all others of its kind that I have seen. It is planted upon a rock, and, possibly because of poor nourishment, has foliage of a uniform dull red color all summer long. It never shows a single green leaf, and, although we do not prize it especially for its effect in the shrubbery, we have found the peculiar tint of its foliage quite attractive in decorative arrangements. The contrast of its rich, subdued coloring with the cool-looking deep green of the *Althæa* foliage, starred with its handsome flowers, is excellent. In this arrangement care was taken to avoid a flat effect by using long sprays and by cutting the *Wild Carrot* with some long stems.

At another time large vases and bowls were filled with the full cream-colored heads of *Hydrangea grandiflora* mingled with sprays of the purple-leaved *Barberry*, which are not purple in reality, but a mingling of rich crimson, dark wine-color and tints of dull green. *Sunflowers* used alone, or with masses of the tropical-looking foliage of *Aralia* and *Sumach*, were found effective at another time. The largest flowers were used for corners in the hall and for fire-places, and the smaller ones for stands and mantel decoration.

Almost all of our garden flowers now in bloom, such as *Dahlias*, *Marigolds*, *Zinnias*, *Phlox* and *China Asters*, have a stiff aspect, which makes them less desirable for cut flowers than their wild neighbors of copse and field. Vines, however, whether wild or cultivated, are never stiff, and I wish here to call attention to the beauty of the common *Trumpet Creeper* when tastefully arranged, for house or church decoration. It is particularly effective for draping mantels, and ample lengths should be cut for this purpose with the large red trumpets naturally disposed amid the foliage. Fire-places and corners may be filled with it, a background of *Asparagus* with red berries giving lightness of effect. *Balustrades* may be wreathed with it, and it may be draped in graceful festoons from the walls. *Wild Clematis*, *wild Grapevine* with ripe grape-clusters,

and the *Virginia Creeper* with its berries, are some other vines that can be often used with fine effect for decoration. One who searches through the shrubberies for material for this purpose finds many odd-looking carpels and capsules and berries, as well as hips and haws. Among a few of these are *Elderberries* with abundant foliage, which are suitable in some arrangements, and mingle well with yellow flowers, and the despised *Golden Elder* is not unattractive used in this manner. A branch of the rare *Fontanesia phyllæroides* was found attractive, its singular light green seed-vessels depending from the twigs in pleasing contrast with its neat foliage of a darker shade. The black seeds of *Pardanellus Chinensis* contrasted with their yellow stems and capsules, may be used effectively sometimes in arrangements of wild flowers. The burnished purplish berries of *Callicarpa purpurea* give variety to bouquets of wild *Asters*; and branches cut from bushes of *Rosa rugosa* may be used by themselves, the handsome little red and orange colored apples hanging effectively among the rich green foliage.

These few suggestions may be useful to supplement the admirable articles upon the subject of interior decoration that have already appeared in GARDEN AND FOREST.

Rose Brake, W. Va.

Danske Dandridge.

### Notes from Germantown.

To the Editor of GARDEN AND FOREST :

Sir,—With reference to the *Black Locust* (see page 338), I have observed that the *Locust borer* is a pest of this tree and that the growing of it for profit is not always satisfactory. On a recent journey from Carlisle to Gettysburg I saw a large number of *Black Locusts*, and in many cases the borer had nearly destroyed them. In some instances the trees had been set out along farm lanes and dividing lines, and I observed some rows in which every tree was partly dead. Usually it was the upper half which was injured.

*English Hollies* do not utterly lack in hardiness if they are surrounded by other evergreen plants while young, and are being planted in this vicinity more than formerly. The Japanese species, *Ilex crenata*, is more hardy than *English Holly* and has small myrtle-like foliage. Of course, our native *Holly* is entirely hardy about Philadelphia.

The long loose clusters of fruit of the *White Fringe-tree*, *Chionanthus Virginica*, are ornamental now. The sterile flowers and the fruits are borne on separate individuals. Sterile plants are sometimes grafted with the fruit-bearing sort, but the grafts do not take readily. Those who have sterile plants may take satisfaction in knowing that the flowers on these are more beautiful than those of the fruitful plants.

The fruit-pods of *Euonymus Americanus* are showy now. The pods are purplish red and warty-looking. The resemblance of this fruit to that of the *Strawberry tree* of Europe, *Arbutus Unedo*, is not altogether a fancied one, and a few years ago tree-agents sold any sort of *Euonymus* for *Strawberry trees*. When quite ripe the fruit of *Arbutus Unedo* is excellent for eating. *E. radicans*, though mostly used as a vine or for an edging to a bed, is an attractive pyramidal object when tied to a stake for a year or two. These plants are sometimes used in cemetery lots, and when trained in this way they closely resemble a *Juniper* in form, and are also evergreen.

*Althæas* have not been as beautiful in many years as they are now, the frequent rains having suited them perfectly. These shrubs could hardly be spared at this season, both because of the number of pleasing varieties and the scarcity of other shrubs in flower at this time. The bushes should be severely pruned in their dormant season to bear the best flowers.

Our wild *Bearberry*, *Arctostaphylos Uva-ursi*, is not found in many collections. It needs a sandy soil and thrives well in almost pure sand.

Germantown, Pa.

Joseph Meehan.

### Some Utah Shade-trees.

To the Editor of GARDEN AND FOREST :

Sir,—The deciduous trees planted in Utah for shade, either in the cities or on the farms, consist almost entirely of three kinds, the *Lombardy Poplar*, the *Black Locust* and the *Box Elder*, although the *Carolina* and *Bolle Poplars* are used to some extent and are gaining in popularity. The *Lombardy Poplar* is by far the most common and is planted, even by men who do not admire its characteristic appearance, because it seems especially adapted to the climate, grows very rapidly and will, therefore, soonest change the somewhat monotonous appear-

ance of most of the valley lands and supply the much-needed shade. It is also probable that its abundance at all the nurseries may have had some influence with those who take what is offered them in the way of trees, without much regard as to its desirability. But whatever the causes, the fact remains that all over the state, wherever trees will grow at all, rows of tall Lombardy Poplars are seen marking the boundaries of farms or the courses of irrigation ditches, a characteristic feature of every Utah landscape. As might be expected from their abundance, the cotton becomes a decided nuisance when it falls, especially in the cities; so much so that in most of the larger cities ordinances have been passed requiring the removal of all Poplars with pistillate flowers. The thrifty nurseryman, taking advantage of this, soon placed upon the market Poplar-trees which bore only staminate flowers, and as a proof of this pointed out to the intending purchaser rows of older Poplars from which the pistillate specimens had been carefully removed.

The Black Locust stands next to the Lombardy Poplar in point of numbers, but does not seem so well adapted to the climate. Borers invade it to some extent, and the older specimens soon present a rather ragged appearance from the large number of dead twigs upon them. Yet the trees will endure many hardships, and are, perhaps, better able to withstand drought than the Lombardy Poplar. I have seen some specimens about old ranch buildings and in similar situations which could at no time have received more moisture than is afforded by the scant rainfall of that region, and yet, although they were but little taller than the Sage Brush which surrounded them, they appeared to be perfectly healthy and had made a considerable growth in thickness.

One accustomed to the Box Elder as it grows through central United States would scarcely recognize the Utah specimens, so tall and straight do they grow. Many of them closely resemble the Soft Maple in general outline, and that is likely to be one's thought on seeing them for the first time in their winter condition. This change in appearance I should ascribe to the fact that the climate of Utah is singularly free from winds, with the exception of those from the cañons, and that the trees are usually planted along the streets of the towns, or if on the farms along the irrigation ditches. As in all Utah cities both sides of each street are provided with small streams of water, it will be seen that in either case the conditions are especially favorable for growth.

The grounds of the Mormon Temple at Salt Lake City are adorned by some very fine specimens of Ailanthus-trees, but their beauty has been greatly diminished by the ruthless manner in which the tops have been mutilated. Just what the object was in cutting back the tops it would be hard to say, for they are not unusually tall and do not obstruct the view of the temple. But they have twice been cut back, the first time evidently almost to straight poles, and the second time hardly less severely. This treatment has materially injured the appearance of the heads, but the boles are very handsome.

That most beautiful of all shade-trees, the American White Elm, is now being planted in considerable numbers in the cities, and is a great relief from the Locusts and Poplars so monotonously prevalent in the older plantings.

Tescot, Kansas. F. C. Sears.

### Recent Publications.

Circular No. 12, issued by the Division of Botany of the United States Department of Agriculture, describes the conditions of successful cultivation of the Camphor-tree, *Cinnamomum camphora*, and the uses of the tree and its products, and contains other interesting particulars. This broad-leaved evergreen is related to the Red Bay and to the Sassafras in the United States, and in general habit resembles the Basswood. In the coast countries of eastern Asia it attains a height of from sixty to one hundred feet and a trunk measurement of from twenty to forty inches in diameter. In Japan the law requires that a new tree be set out for every one cut. It is stated that the northern limits in the United States where this tree has been grown successfully out-of-doors are Charleston and Summerville, in South Carolina; Augusta, Georgia, and Oakland, California. In the southern cities named the trees have withstood a temperature of fifteen degrees, Fahrenheit, but they were protected by surrounding trees and buildings. At Mobile, Alabama, they have grown and fruited in protected situations, while in exposed places they have been repeatedly destroyed by frosts. They will grow in almost

any soil that is not too wet, but do best on a well-drained sandy or loamy soil, and respond to fertilizers. While of comparatively slow growth on sterile soil, the trees grow very rapidly under favorable conditions. An exceptional instance is recorded of a Camphor-tree in Italy which in eight years from the seed measured one foot in diameter and ninety feet in height. Trunks six to eight inches in diameter at the base and thirty feet in height may be expected in trees ten years from the seed under favorable conditions. Besides the familiar use of camphor-gum to protect furs and woollens against insects, this gum is used extensively in medicine. Camphor-oil, which is somewhat similar to turpentine, in Japan enters into lacquer-work, and it is also used in the manufacture of toilet soaps. The yellow wood is of close grain and is susceptible to polish, taking a satin-like finish; this is particularly valuable in cabinet-work, especially for drawers, chests and cupboards, being proof against insects. The tree produces an abundance of berry-like fruits, which in China and Japan are used to make a kind of tallow; these are also a favorite food of chickens and birds. Besides these commercial uses, the tree has value for ornamental planting, and has been extensively introduced into southern Europe and South America for this purpose. For successful cultivation the minimum temperature must not be lower than twenty degrees, Fahrenheit, and this interesting circular suggests that it is hoped by continued selection of seeds from the most hardy trees plants may be bred up to endure more cold. Camphor of good quality has been produced in Florida from the leaves and twigs of trees less than twenty years old, one pound of crude gum being obtained from seventy-seven pounds of leaves and twigs. One-third of the leaves and young shoots may be removed at one time without materially checking the growth of the tree. The older and larger roots yield the largest proportion of camphor; the trunk, limbs, twigs and leaves contain successively a decreasing proportion. Present methods of distillation are here described and improvements suggested.

Within the past ten years there has been an increase in importations of refined camphor in the United States and a decrease in importations of the crude product, notwithstanding the former is dutiable while the latter is admitted free. Improved methods of refining and packing in Japan and a reduced tariff rate account for this change. In 1887 there were imported 2,873,184 pounds of crude camphor, valued at \$352,861, and in 1896 but 943,205 pounds, valued at \$328,457. In 1887 only 307 pounds of refined camphor, valued at \$45, came into this country, while in 1896 153,912 pounds were admitted, worth \$68,785. These figures show that the price of the refined and the unrefined product has increased three-fold in this period, and that the consumption of camphor in this country, as measured by importations, has been decreasing. This decrease is attributed to exhaustion of the supply of available Camphor-trees near the shipping ports, governmental restrictions on the trade in camphor in Formosa and taxes on the exportation, hostilities and wanton destruction of camphor stills by the natives in Formosa, disturbances in the camphor-producing district of China, the China-Japan war, and attempts by speculators to corner the market. The increase in the price of camphor has led to the introduction of substitutes, and camphor has been manufactured artificially at a cost which leaves a margin of profit at present prices. The conclusion is that if the production of camphor from trees is to be carried on with profit in this country and the industry increased to any considerable extent, the price of camphor must be reduced to compete with the prices of substitutes now taking its place.

### Notes.

Mr. R. A. Rolfe notes in *The Orchid Review* the discovery of a natural hybrid between *Orchis maculata* and *Habenaria bifolia*. This interesting addition to the British flora was

found on a moor six hundred feet above the sea-level, near Glenalmond, Perth. A hybrid between the same genera was found in France in 1891.

Florida papers state that photographs recently made for exhibition show twenty-eight pineapples, estimated to weigh about 400 pounds, growing on a plot of ground ten feet square, near Orlando, in that state.

The receipts of bananas at this port during the month of August amounted to 420,100 bunches, and exceeded the business of the same month in last year by 138,500 bunches.

In the Forestry Building at the Tennessee Centennial Exhibition forty-five different kinds of hard wood are shown as the product of a single farm in Montgomery County, Tennessee.

The peach crop of Missouri is immense this year, and a conservative estimate of the yield in five of the great fruit-growing counties in the south-western part of the state is 412,500 bushels. The output of a single farm of 1,600 acres in Oregon County this season is 15,000 bushels.

A Penn Yan correspondent of the *Fruit Trade Journal*, writing from the grape region about Lake Keuka, New York, reports the grape crop to be two weeks later than last year. There is promise of a two-thirds yield of Delawares and a large crop of Catawbas if the frost holds off, while Concord will not give the average yield.

The American Fruit-growers' Union will hold a convention in Nashville, Tenn., on September 8th to 10th. It is proposed during its sessions to form an association comprising the fruit and vegetable growers of the entire country, particularly southern growers. The entire north and west is dependent upon the extreme south for early vegetables up to May 15th.

One of the most famous trees in Connecticut is the so-called Poetry Oak which stands in front of the meeting-house at Pachaug. The agricultural papers of half a century ago commented upon its size, and a more recent writer says "it has heard fifty-two sermons a year for 177 years and political speeches from the settlement of the country down to the present day," and reports that its trunk is nearly twenty feet in circumference while the spread of its branches exceeds 240 feet.

The so-called Panama hats, beautifully woven and very expensive, come in large part from Central America. But about five million hats of a similar kind, although of different grades, are annually exported from Spain, where in the Andalusian district, they are manufactured from the leaves of a species of Palm which there grows almost wild. They are made entirely by hand, after the methods pursued for centuries, and the industry is said to support more than ten thousand persons, mainly women and children. The finest kinds can be made only by skilled operatives, who consume a week in producing two hats.

A new hybrid *Aristolochia*, probably the first of which there is record, is figured and described in a recent issue of *The Gardeners' Chronicle*. The parents, *A. Brasiliensis* and *A. elegans*, belong to two very distinct sections of the genus, and the upper lip of the hybrid is described as intermediate in shape between that feature in the parents, slightly crumpled, cream-colored, thickly bestrewn with arborescent purplish spots. The throat of the perianth is clear yellow, as in *A. elegans*, with numerous purplish radiating veins. This interesting and showy novelty is an acquisition to the stove climbers, and was originated by Mr. J. M. Bell, gardener to Rev. Canon Prettyman, Louth.

A bulletin on vegetables just published by the West Virginia Experiment Station reports that the same quantity of field beans planted in drills will produce twice as much as if planted in hills. Where but a few plants of Lima beans are grown for family use it is recommended to plant the seeds in inverted sods in a hot-bed, from April 1st to 10th, as the increase will more than repay the trouble. Bush Lima beans are compared favorably with the pole sorts and said to be worthy of taking their place. The saving of poles and training would, of course, be a clear gain. The bush sorts are said to require less space for development, so that a larger yield per acre may be counted upon, particularly toward the northern limit of the successful cultivation of the pole Limas. The limit of the successful cultivation of bush Limas is said to be much farther north than that of the pole Limas.

In 1895 four public playgrounds for children were opened by the Philadelphia Board of Education. Eight more were added in 1896, and ten additional ones this summer. The cost

of equipping the twenty-two which are thus doing service was only \$3,000, while the attendance at each averages from 300 to 600 persons a day, according to its situation in a more or less densely crowded quarter of the city. Of course, the majority of the frequenters of these playgrounds are children. But poor mothers often pass a part of the day within them, while others leave their children, including even babies in carriages, in the care of the janitor and teacher. Large sand-piles form the chief attraction, but in some grounds swings, seesaws, toys and games of various kinds are supplied, and as much shade as possible is always furnished.

Among eighteen papers included in the proceedings of the Society for the Promotion of Agricultural Science, at its annual meeting held in Detroit last month, were An Experience in Managing a Weed Garden, by Professor W. J. Beal; Notes on Bean and Pea Tubercles, by Professor B. D. Halsted; The Annual Growth of Forest Trees, by Professor W. R. Lazenby; Objects and Methods of Soil Analysis, by Professor E. W. Hilgard; The Promotion of Agricultural Science, by Professor I. P. Roberts, and Further Observations in Varieties of Timothy, by Professor A. D. Hopkins. Professor Halsted, of the New Jersey Experiment Station, was elected president for the coming year, and Professor C. S. Plumb, of Purdue University, was made secretary and treasurer. This society, founded in Boston nearly twenty years ago, has for its object the advancement of progressive agriculture. The membership list is increased only by invitation to scientific workers and is limited to one hundred. The next meeting will be held in Boston in August, 1898, in connection with the fiftieth anniversary of the American Association for the Advancement of Science.

Our native Squaw-root, or Cancer-root, *Conopholis Americana*, is illustrated and described in *Meehan's Monthly* for September. This singular and somewhat uncommon plant is best known in its mature condition, when the small clusters of blackened spikes resemble slender old Fir-cones. While widely distributed over the eastern and central portions of the United States, it is nowhere common, and about Philadelphia is stated to be the most rarely found in a list of rare plants. It is in bloom in that vicinity toward the close of April, though in a late season its curious flowers do not appear until the beginning of June. The parasitic tubers have a preference for the roots of Oaks, but individual plants and groups are sometimes supported by a few straggling roots which penetrate from three to six inches of peaty bank. The plant is elusive because it is often unable to pierce through the heavy crust of decayed leaves. The flowers, which develop and perfect themselves in four to six days, rarely, if ever, produce fruitful seed, and the plant perpetuates itself mainly from eyes in its thickened corm-like tuber. The resemblance to its near relation, the Beech-drops, also known as Cancer-root, *Epiphegus Virginiana*, is noted in several particulars.

In an editorial article recently published in the Boston *Transcript* it is stated that the action of New Hampshire toward the prevention of destructive tree-cutting is most closely watched. Not, perhaps, because the denudation is most pronounced there, but because from its attractiveness as a summer resort the losses to its forests are the more evident to the traveler. No one who traverses the wild road leading up to the Old Man of the Mountain can help bewailing the short-sighted policy that is denuding these hillsides and valleys. Here the woods are so deep and so extensive that deer may occasionally be seen crossing the public roads. But for five miles up the valley there is the sawdust trail of the woodcutter, who mows the forest from the mountain side and chokes the rivers with his refuse. And this is the condition of New Hampshire's choicest retreat, where as much land as possible has been retained by careful and intelligent owners, who realize that when the forests are gone New Hampshire's attractions for summer tourists will be gone also. Three-quarters of the cutting in New Hampshire is of that sweeping kind that leaves not even a sapling on the denuded area, but the Legislature has not yet given signs by its acts or its appropriations of serious intention to stop the waste. The present course cannot fail to rob the Granite State of its forests, and will make it impossible to replace them by other forests. The remedy will probably come in protests from persons interested in the summer resorts. When they realize that the income derived by the state from its visitors is quite equal to that derived from the cutting of lumber (and this was stated to be true a number of years ago), they will see to it that their interests are not imperilled further by reckless lumbering.

## The Improving of Native Plants.

HISTORIES are mostly unreliable, and the histories of our fruits and vegetables are no exception. Few can see the value of any occurrence at the time when it takes place, and it is only in after years, when the results are apparent, that we begin to look about for the attending circumstances. This truth is evident when reading the histories of our fruits and garden vegetables. We know that they were derived from wild forms still in existence, and that they reached their present conditions only after long and patient experiment and display of skill. The monks of old especially are credited with the expenditure of much study in bringing our garden vegetables to their present state of comparative perfection, and possibly to them we are indebted for much that is good in them. The fact is that there is no great amount of knowledge or skill required to produce these improvements from the wild stock. Perseverance in selecting individuals which vary somewhat from the usual forms, sowing seeds of these, and choosing plants which are nearest to our ideal, and following up this for a few generations, represent the knowledge and skill necessary. A few years of perseverance are required, and this the monasteries were in excellent condition to give. It is no wonder, however, that the uninitiated look on with awe at the change, and that polite history credits it to the great skill and knowledge of the improver. The Beet-plant may now be drawn from its native soil with its long thready root no thicker than a goose quill, and it seems incredible that this should be the parent of the Sugar Beet. So also the parent of the Cabbage may be gathered with a couple of leaves not as large as one's hand and a six-inch spike of yellow flowers, and yet from this unpromising origin came Cabbage, Kale and Cauliflower. And these improvements have been brought about by simple selection and resowings from some one aberrant plant.

It is somewhat surprising that no one has taken in hand the improvement of our native vegetables to any great extent. Certainly we have Corn, Beans, Tomatoes and a few other plants that are natives of our continent, but these we received from the natives before us. We, from the old world, have done nothing for the vegetables of the new world. We go to China for Chingi when our own species of Stachys and its near neighbor, Lycopus, have tubers

nearly as good. Our native Indians could tell of scores of roots that would be as good as many of our popular vegetables if taken in hand and selected for improvement as others have been.

In 1804-5-6 a wonderful event occurred in the successful crossing of this great continent for the first time, and the return to the "village" of St. Louis by Captains Lewis and Clark and forty-three companions. Among the instructions given them by President Jefferson was one to take notes of plants that might be serviceable to man. A collection of plants was made by them which has not been seen since the botanist Pursh's time until this summer, when it became my good fortune to find it in the vault of the American Philosophical Society in Philadelphia, Pennsylvania, where these specimens, with others, were deposited after Dr. Barton's death. Under the specimens are full notes of their uses by the Indians. These great explorers were not botanists except in the general way that intelligent persons of a few generations back were expected to have an outline knowledge of every school study. They knew, for instance, that certain plants belonged to the umbelliferous family, and others to the Lily family, and they went this far in their written descriptions. It is especially surprising to note the number of members of the Umbelliferae in use as food, and we still have in our gardens Celery, Carrot, Parsnip, Parsley and others; but because there happens to be one fatal Hemlock among them, the whole family is under suspicion. On one of the labels is written, "This umbelliferous plant is the only one whose root is not eaten by the Indians." Unfortunately, during the three-quarters of a century that the specimens have been bundled up, the museum beetle has done effectual work, and not a scrap of the plant is left to which this label was attached. Another label tells us "The Indians use this root, boiled or raw. It has a fusiform root, not unlike our common carrot, and, indeed, the leaves are somewhat of the same character. They taste like sugar." Surely such good material is worth investigation and study. These labels suggest that there is scarcely a starchy or succulent root but is good for food. Even our common Silver-weed or Goose Grass, Potentilla anserina, has a place in this useful list, and a label tells us that "we found them very pleasant when roasted, resembling in flavor somewhat a sweet potato."

In the busy days of the modern American the few years of trial required to bring up American weeds to the rank of useful vegetables cannot be spared. But our agricultural colleges more than supply the place of ancient cloisters. With a wide knowledge of science, with skill in experimentation, the officers of our colleges and stations are much more completely equipped for this work than were the monks or any one else of their generation. At least, here are two fields in which they would have practically no rivals. In the first place there is a mass of bibliographical work of the past century which can be arranged for useful reference, so that we can preserve the gains our predecessors have already made. And again there are wild plants everywhere which by careful selection might be transformed into edible foods of the highest value. We do not refer, of course, by this to the nuts and berries exclusively, but to salad plants and garden plants for preparation in other ways that will add variety and value to our foods.

Germantown, Pa.

Thomas Meehan.

## Wild Flowers of Early September.

WITH September the reign of the Golden-rod and the Aster is established, though it is not at once supreme. Some of the August flowers, and especially the tall late-summer "weeds," are still prolific and lusty; and certain later comers help them to dispute the conquest of field and roadside with the two great autumnal genera.

The showiest of the Eupatoriums, the showiest of all August flowers—the Joe-Pye Weed—is past its best. Many

of its great pinkish-purple bouquets still sway in the wind, sometimes at twice the height of a man, but for the most part they are now faded and dry. The white Boneset, however, still flourishes; and the most beautiful member of this genus has just reached its best. August does not show the White Snakeroot, *Eupatorium ageratoides*, as early September shows it. And it is not merely a chief ornament of these particular days. It is one of the most beautiful of the Compositæ, and no more charming flowering plant of an analogous kind grows in any garden. Through the fence, from the woodland border, in the meadow thickets, it spreads its polished dark red branching stems, bearing their numerous corymbs of blossom. Its flowers are larger, more brightly white, and less hairy-looking than those of the other *Eupatoriums*, and Nature has done so well with this plant that the gardener would not need to "improve" it to fit it for frequent use in the pleasure-ground. Indoors it looks best when arranged by itself, for its own stems and leaves and flowers furnish contrast enough, and none of their charm ought to be hidden. It is appropriate for small bouquets for mantel or table decoration, as well as for large arrangements, simulating its effect as it grows. But in neither case should it be too closely massed. Its graceful habit and the color of its branches should always be revealed.

The most conspicuous plant which is now in its prime is the many-branched form of the Button Snakeroot, also called the Blazing Star, although it is hard to see why, for its heads are not star-shaped and their color is a deep red-purple. When it grows under favorable conditions where it has plenty of moisture, the rich-hued "buttons" of *Liatris scariosa* are remarkably numerous, and are well set off by the very dark green of its abundant foliage. It is not one of the more graceful Compositæ, but it is stately and handsome. It may be massed in house decoration because Nature grows it in masses. And its dark tones may well be relieved, as Nature often relieves them, by the admixture of a few sprays of Golden-rod. But it should never be combined with Asters. Their more delicate habit unfits them for its companionship, while when their blossoms are blue or lilac they do not harmonize with its redder purple.

The most popular flower of this season is undoubtedly the red *Lobelia*. The most careless eye cannot ignore the Cardinal-flower as its graceful spike flames against the dark hollow above a shadowed pool or springs from a brookside tangle. The village child delights to discover it, and the most captious taste need ask nothing more beautiful than its distinctive form and dark velvety red color—the most beautiful red, in tone and in texture, which any of our wild flowers can show. Nevertheless, when the Cardinal-flower is brought home and put in water its effect is usually a disappointment. This is because it is most often arranged in bunches with only a slight admixture of green. Its color then survives; but the effect, as of a lance-like flame, which was so enchanting in Nature, has disappeared. If a bowl is filled with foliage and then a few tall spikes of the Cardinal-flower are set in it one by one so that the individuality of each is preserved, a much better result will be attained. And the foliage ought to be of the darker greens, like the leaves of the plant itself. So deep a red as that of this *Lobelia* does not contrast well with yellowish greens.

Admirable, too, is the Great *Lobelia*, *L. syphilitica*, with its flowers of an intense blue, rivaled only by the blue of the *Gentians*. It has not the grace of *L. cardinalis*, nor its vivid effectiveness, but is a desirable addition to the resources of the decorator of the house at this particular season. It will be forgotten when the *Gentians* come, but as yet only one of these is available. This is the Closed *Gentian*, *G. Andrewsii*. Delightful in color, it is stately and decorative in habit, and is well worth seeking, for it lasts longer after cutting than almost any other flower of the season. Nothing else should be combined with it. Its strong stems should lift their fine whorls of dark green

leaves and their clusters of oval blossoms, deep blue streaked with white, from the glass or vase undisturbed by contrast with any plant of another habit and color.

The various Compositæ of the genus *Prenanthes* (the Rattlesnake-roots) now add variety to the roadside and forest border. The tall, slender stems and slim panicles of nodding heads which some species produce have an attraction peculiar to themselves, and much of it may be preserved when they are brought indoors if Nature's methods of arrangement are again observed. The flower-stalks should be kept of their full length, or nearly so, only two or three of them should be used, and they should be allowed to rise well above the general level of the contents of the vessel in which they are placed.

The Swamp Loosestrife, *Decodon verticillatus*, is not yet out of bloom, and the light pink of its delicate blossoms makes it peculiarly attractive at a season when purples and yellows so largely carpet the earth. This plant, sending out near the ground long recurved stems covered with whorled leaves and axillary clusters of flowers, should not be arranged in the house to simulate the aspect of erect-growing plants. A number of its stems should be placed in a low flat vessel, curving outward from it in all directions, and this vessel should be set on the floor so that the eye may look down upon it as it does upon the plant itself when it grows in the wet ground by the pondside.

Every one who loves plants must long ago have discovered for herself the best ways in which to make use of the Golden-rods and Asters. And the many berries which are available at this season are not difficult to manage. Common sense decrees that they should be shown with their accompanying leaves as they grow on the branches. But there is one plant, the White Baneberry, the fruit of which is conspicuous just now, which teaches an interesting lesson in regard to natural beauty. This is the lesson that if any of Nature's products seems ugly, it is because it is taken out of its right environment. Even a snake is beautiful as we catch a glimpse of it gracefully gliding among thick foliage. Even a bullfrog is very handsome as he sits on a half-submerged log, half-submerged himself. And even the flower which is least attractive when put in a vase or held in the hand and examined, has its own peculiar charm when seen, or half-seen, amid its natural surroundings. This lesson is strikingly enforced by the fruit of the White Baneberry. When examined it is distinctly ugly. The white berries, each perched on the end of a thick stiff red stalk, and these stalks set stiffly at wide intervals around the stem, look as though, not the skillful hand of Nature, but the 'prentice hand of some human workman had both shaped and colored them. The spike looks as though it had been manufactured, not grown, and manufactured with dead wood and paint, not with vital vegetable tissues. Yet a spike of White Baneberry as it grows in the roadside tangle, revealing itself as shining sparks of white and lines of crimson, is a very delightful object. It is wisest to admire it and pass it by. No good effect can be produced with it if it is picked and brought home. And much the same may be said of the thick scarlet spadix of the Jack-in-the-pulpit.

By the seashore many delightful plants which are not named here may be found in early September. But even amid the less varied flora of the hills there is one which must not be forgotten. It is very lovely in itself, and it is all the more attractive because strength and showiness, not extreme delicacy and fragility, are the qualities we look for in the plants which blossom at this season. No vernal plant exceeds the Slender *Gerardia*, *G. tenuifolia*, in the qualities which its names denote. Some of its larger yellow-flowered brethren still show their blossoms, although their real season is August. But only an examination of the fashion of their flowers could suggest that they are indeed its brethren. It is impossible to describe the delicacy, the fragile, airy grace, of this little species with its tiny almost thread-like leaves, its rosy purple flowers, and its paler, almost white, globular flower-buds. The red and

yellow Columbine of spring seems almost sturdy if we think of it in comparison, and even the Harebell is not so frail. On woodland banks or open meadows it is exquisite indeed, and if rightly treated indoors it preserves its charm. Nothing else should be mixed with it, but if a loose bouquet of it is put in a thin white glass vase, the beauty of the open flowers and the spark-like effect of the unopened ones will delight the eye for a few brief hours. On the morrow it will have withered. But who would expect a flower like this to "last" as does a Golden-rod or a Closed Gentian? The only marvel is how its fairy-like frame can furnish sap enough for the elaboration of its lovely flowers.

Tuxedo Park, N. Y.

M. G. Van Rensselaer.

### Some Facts about Frost Prevention.

**I**N few countries have methods for the prevention of injury by frost been so systematized as in France. The nature of many of the crops and the peculiar situations they often occupy have demanded extreme vigilance at critical periods or total loss has followed. Prior to the comprehension of the principles involved in these methods, and even at the present day in less enlightened communities, the disturbing cause of frosts has been that arch-enemy of agricultural practice, the moon. This innocent luminary has, in the past, exercised as baneful an influence over the fruit crops of France as it does in certain benighted Potato-fields in America at the present day. It was not until long after the physicist Arago had explained the cause of these late spring and early autumn frosts that the superstitious peasantry gradually lost faith in the blighting efficacy of moonbeams. These frosts, Arago demonstrated, are due to the rapid radiation of heat from the earth, always augmented by still air and a clear sky, but retarded by clouds and wind, the former acting as a blanket to check the escaping heat, the latter preventing the air from settling in pocket-like formations in the general contour of the land.

Coverings of paper and other materials commonly used to protect flower-beds would in themselves be too slight a protection but for the check they give to the heat and moisture escaping from the ground. The relatively high temperature maintained under these coverings is due to the continual evolution of heat which accompanies the condensation of moisture. To protect small areas or a limited number of specimens, French gardeners use straw matting, bell-jars, various kinds of frames and screens, which latter are, as at Montreuil (in the vicinity of Paris), hooked to permanent or temporary supports. This last method was brought to France, by way of England, from Scandinavia, where it has been used time out of mind for the protection of wall fruits.

A unique method for tree protection is the hanging of a thick rope from a high branch of the tree, the lower end being in a pail of water. *The Farmers' and Planters' Encyclopædia* remarks that "should a slight frost take place at night it will not in the smallest degree affect the tree, while the surface of the pail, which receives the rope, will be covered with ice; the water placed in another pail by the side of it, by way of experiment, may not from the slowness of the frost, have any ice on it at all." In this case the rope, by exposing a large surface to the air, aids the evaporation of the water carried up by capillarity, and the heat evolved by the condensation of this water among the foliage raises the temperature above the line of danger.

When plants are covered by hoar frost they may yet be saved, say Decaisne and Naudin (*Manual de l'Amateur des Jardins*, vol. i., page 624), by sprinkling them freely with water, which loosens and removes the ice and gradually raises the temperature of the plant to its normal degree of heat. Doubtless this is a somewhat sweeping assertion, since the damage may have occurred at the time of freezing. And damage at the time of freezing seems all the more probable from the following experiment recorded by Stewart. Two sets of smudges were placed in different

vineyards equally exposed. In the first, they were lighted one hour before sunrise; in the second, when the temperature reached the freezing-point. In the former the buds were frost-bitten; in the latter, unhurt. Some plants can stand a good deal of frost without being injured, while others are permanently disabled by temperatures not below the freezing-point.

The practice of smudging is more ancient than is usually supposed. De Serre, a prominent agriculturist of the sixteenth century, recommended it, and it is even said to have been favorably spoken of by Pliny. In Wurtemberg, in 1796, the men were divided into companies of about twenty, under a captain, to protect certain assigned districts, and were called out by an alarm given by a regular watchman. This service was compulsory, since article seven of the rules reads that whoever "shall refuse to obey, shall be prosecuted before the bailiwick, and receive exemplary punishment."

Even long after the practicability of frost prevention had been demonstrated, fruit-growers, instead of testing the methods, as a rule continued to accept its ravages as a thing to be expected, but not avoided. But of late years they have commenced to see the benefits derived, and the use of smudges has been growing in popularity. These are made of almost any substance, such as dampened straw, manure, tar, sawdust, crude kerosene; in fact, anything which will produce a smouldering fire with much smoke and little blaze. Besides these substances, various compositions have been put upon the French and other markets. One of these, Lestout's (considered the best), is sold in the form of bricks, which weigh sixteen pounds, and cost about fifteen cents each. They are placed about thirty feet apart, and lighted at the approach of danger. A tract of about 2,200 acres may be protected by 300 of these bricks at a cost of about one cent per acre per hour for the material. The smudge formed will, in still weather, be effective for about two hours, when it may be renewed if necessary. In many orchards and vineyards these smudges are fired automatically by various devices. These are not often satisfactory, since the machine lights all fires at once, in which case, if there be but a slight breeze, the smoke from the leeward smudges is lost, while that from the windward fires is liable to be too much diluted with air to be effective.

A district rather than an isolated plantation should be protected. This is best accomplished by organized effort on the part of all proprietors owning crops liable to injury. One such company of 115 growers was formed at Moulis, in Medoc. Their operations were very successful. The cost of protection was only twenty-five cents a thousand vines for the season, a figure which could not be reached by individual protection.

The success attending the application of protective methods may be still further seen in the following cases: At Lussac, in Medoc, on April 21st, 1887, the trellis wires were covered with ice. Smudges were lighted at two a. m., and not only were the crop and the vines saved, but even the tenderest foliage covered by the cloud was uninjured. At Cornell University, in the autumn of 1896, the whole of the Dahlia and Canna plantations, which were in a hollow from which the cold air could not escape, were successfully protected by the smudge and water methods. At the Michigan Agricultural College, a few years ago, beds of Geranium and Coleus were saved by the water method, and were in fine condition some weeks after even less exposed beds had succumbed.

This water method consists simply in a liberal drenching of the plants and the ground on the evening when frost is expected. If there be a rise of ground in the immediate vicinity of the plants to be protected, it should also be wetted down so that the air which flows over it toward the plants will be saturated with moisture. When the temperature falls, water vapor is condensed, a large amount of latent heat is evolved and the temperature of the air is raised. Of course, when general freezes overspread a wide

area of country, nothing can be done to prevent injury, but when the fall of temperature is slight, either the smudge or the water method, or both together, will prevent injury, which would almost certainly occur if nothing were done.

Department of Agriculture, Washington, D. C.

M. G. Kains.

## Foreign Correspondence.

### *Grammatophyllum speciosum.*

SIR TREVOR LAWRENCE exhibited a full-sized spike of flowers of this, the largest of all known Orchids, at the last meeting of the Royal Horticultural Society. It was, of course, awarded a first-class certificate, and to this was added a gold medal for the cultivator, Mr. White, under whose skillful management the rich collection of Orchids at Burford Lodge has been for the last ten years. From time to time attention has been called to this giant among Orchids either by travelers who have seen it in all its glory in Malasia, where it is a native, or by collectors who have sent home big specimens of it in the hope that its magnificence might be seen here. But, although it has, as a rule, grown freely, it has failed to flower, except in rare instances. The Burford Lodge plant has been in the collection at least ten years, and has only flowered now, and that, too, after a course of treatment which, from its effects on the stems and leaves, might be termed drastic, but in that it has brought about the desired result it has proved to be so far correct. The Kew specimen of this *Grammatophyllum* is about four times as large as that at Burford Lodge, and it is in the best of health, some of the pseudo-bulbs being ten feet long, as thick as a man's wrist and clothed with leaves from base to tip, but it has not yet flowered. The spike produced by Sir Trevor Lawrence's plant was seven feet high, as thick as a man's thumb, and it bore thirty expanded flowers of a yellow and purple-brown color, each five inches across; the pedicels were four inches long, rigid and of a whitish green color. There were about thirty unexpanded buds at the apex of the spike. A peculiar character in this and several other genera is the production of two or three abnormal (male) flowers at the base of the scape, in which the segments are reduced to four and the lip is suppressed.

Large, however, as is the specimen of this Orchid to be seen at Kew, it is a mere pigmy when compared with the dimensions given of examples seen wild and in gardens in the tropics. For instance, in 1892 Mr. James Veitch saw in the Botanic Gardens at Penang a single specimen which measured forty-two feet in circumference and bore thirty spikes of flowers. In the following year, according to Mr. Curtis, the Superintendent of the Penang gardens, the same plant produced twenty-four spikes, each seven feet or more long, and bearing fully one thousand expanded flowers. It was, he says, growing on a mound three to four feet high, where it got the full sun all day after about nine in the morning. Once or twice a year half a cart-load of leaf-mold was scattered among the roots, and this was the only attention it received. The finest plants found growing wild in Penang are usually high up in the forks of large trees, where they get abundance of sunlight. The Kew plant was imported from Penang in 1893 by Messrs. F. Sander & Co., who intended it for the Chicago Exhibition, but it got too much damaged in transit to be worth sending.

The history of this Orchid is given as follows in Veitch's *Manual of Orchidaceous Plants*: "This gigantic Orchid excited the wonder of travelers in Malasia long before it found its way into British gardens. The physician Rumphius was probably the first European scientist who became acquainted with it, and through him, or through Osbeck, who visited the Malay Archipelago about the middle of the last century, it became known to Linnæus and to his successor, Oloffe Swartz. Many years afterward it was detected by Finlayson in Cochinchina, and by the French botanist Gaudichaud in the Moluccas. . . . But it was not

till Blume published a colored plate of it in *Rumphia*, nearly a quarter of a century later, that the true character of the plant became known, and the surprise of botanists and the longing of horticulturists were awakened. It was first flowered imperfectly by Loddiges in the Hackney nursery in 1852; again in 1859 in a private collection in Surrey, and from this the fine picture published in *The Botanical Magazine*, t. 5157, was made. This plant had stems from nine to ten feet long and a scape six feet high with flowers nearly six inches across and of a rich yellow color, heavily blotched and spotted with red-purple. A plant flowered some years later in the collection of Sir G. Staunton at Leigh Park, from which a fine drawing was prepared by Fitch and published in 1876 in *The Gardeners' Chronicle*, and this drawing is repeated in this week's issue, together with drawings of the abnormal or male flowers prepared from Sir Trevor Lawrence's plant.

From my knowledge of this Orchid I should say that in the United States, where sunshine is more abundant and intense, the flowering of it would be easy of accomplishment. It likes plenty of moisture, both at the root and overhead, and it soon fills a bed of fibrous peat with a doormat-like mass of roots. It is in every sense a grand plant for a large tropical stove.

MARLIAC'S NYPHÆAS.—The best of the hybrid and seedling Nymphæas raised by the French nurseryman, Monsieur Latour-Marliac, are of quite sensational beauty and interest. There is a collection of them at Kew, comprising all the best of those so far distributed by the raiser, and they have won universal admiration even from cultivators well acquainted with the older Nymphæas. The new sorts are just the plants for small aquaria, or even for cultivation in casks, as they do not grow rampantly as do those of *N. alba*, *N. tuberosa* and others of that ilk, but from a usually solitary crown spring a loose rosette of leaves and set in the midst of them, jewel-like, one, two, three, or even six flowers of varying size and shade, according to age, but all beautiful, richly so, in color as in form. They are expensive, it is true, as Nymphæa prices go, but they are worth all they cost.

FICUS RADICANS VARIEGATA.—This is a pretty little creeper which has been introduced by Mr. W. Bull, of Kings Road, Chelsea, who exhibited plants of it at the Temple Show last May, and again at the last meeting of the Royal Horticultural Society, by whom it was awarded a first-class certificate. It grows as freely and is as clean-looking as the type, while in the cream-white variegation of the leaves, which are oftener more white than green, we have a character that is likely to make the plant exceptionally valuable for clothing walls, pillars, rockeries, etc., in warm houses. According to the most recent monograph of the genus *Ficus*, *F. radicans* is a native of India and Malaya and its correct name is *F. rostrata*.

London.

W. Watson.

## New or Little-known Plants.

### *Hydrangea paniculata.*

UNDER the general name of *Hydrangea paniculata* there are four distinct plants in our gardens:

(1) A plant known as *Hydrangea paniculata grandiflora*, with enormous panicles of sterile flowers which open late in August or early in September, and now one of the most commonly cultivated shrubs in the northern and middle states.

(2) A plant which appears to be the wild form of the last with much smaller panicles appearing at the same time, only a few sterile flowers being scattered among the fertile flowers.

(3) A plant intermediate between these two and flowering at the same time, the panicle being nearly as large as that of No. 1, and more showy than that of No. 2 by the presence of a larger number of larger sterile flowers. This as a garden plant is, perhaps, the most desirable of the whole group.

(4) A plant similar to No. 2, from which it differs only in its time of flowering, which is during the first half of July, or about six weeks earlier. A flowering branch of this form appears in the illustration below.

tainous regions of Japan, and where it becomes a tree twenty-five or thirty feet in height, with a short well-formed trunk a few inches in diameter and stout pendulous branches.

Fig. 47.—*Hydrangea paniculata*.—See page 362.

It is from a plant raised in the Arnold Arboretum from seeds gathered in 1892 by Professor Sargent in the forests of central Yezo, where *Hydrangea paniculata* is exceedingly common, as it is further south in all moun-

Whether two species can be distinguished in this group, or whether we have only an early and a late flowering race of one species, we have not yet sufficient information on which to base an opinion.

## Cultural Department.

## Colchicums.

**COLCHICUMS** have a curious habit of pushing rapidly up from the bare earth and expanding their glowing flowers without a hint of foliage. However often seen these flowers are a surprise each season, as they give no token of their coming. While they are interesting plants in the garden, filled though it may be at this time with the tall and brilliant flowers of the season, their best effect is had from clumps planted in the meadows or on the borders of grass lands. For the wild garden they are invaluable and very effective. They maintain themselves and increase fairly in rather light, moist soil. As the bulbs are dormant only in June, July and August they should be moved at that time. The color effect is their principal value in such places, and *C. speciosum*, the bright reddish purple species from Asia Minor, is best for such plantings, especially as it is plentiful. For the more contracted garden one may indulge in some of the other species whose beauties bear closer examination. One of the handsomest is *C. Sibthorpii*, a large-flowered form which has glowing reddish purple flowers with some trace of white on the inside of petals, checkered with red. This is a free-flowering species, and, perhaps, the most attractive of the family.

Another species will soon appear, *Colchicum Parkinsoni*, a small-flowered Grecian form with purple bars and checkerings in a white ground. This species has not done well in my borders.

Much later than these and flowering late in October usually, is the white form of *Colchicum autumnale*. A double form of this species which has flowered regularly here for some years has a distinct flower with many narrow strap-like petals. It generally has a rather hard time of it, owing to the usual inclemency of the weather, but might appeal less to one's sympathies if grown under a mat of foliage or in some thin grass. There are about two dozen species of *Colchicum*, some of which flower in the spring-time.

*Colchicum* bulbs contain a virulent poison, but have been a favorite prescription for rheumatism for untold generations. I do not know whether they are a remedy or a tradition.

Elizabeth, N. J.

J. N. Gerard.

## Notes on Gladioli.

**THE** flowering season of *Gladioli* is nearly past for this year, with the exception of young seedlings and bulbs planted late for the production of late blooms. The season has been, in this part of the country at least, much better than in 1896, both as to the quality of the flowers and the general vigor of the plants.

It is sometimes said that the *Gladiolus* has reached as high a degree of excellence as can be attained, but those who by raising seedlings and in other ways keep themselves informed will not agree that such is the case. There is a constant increase in the length of the spikes and the size of the blossoms, and we now look upon the varieties of even five years ago as inferior and hardly worth cultivating.

Speaking for myself, I notice year by year an improvement in the substance of the flowers, so that often the fifteenth and sometimes the twentieth flower expands while the first is still in good condition. That the colors improve I am not prepared to say; we have not yet a single good yellow hybrid of any shade, from straw-color to orange, and until we have good ones of every shade there is still work for the admirers of this noble flower. No doubt some will dispute the statement I have just made, but to my mind no yellow flower which is streaked with purple, as they all are, can be called good. There is no *Gladiolus* yet of the very dark shade found in *Africaine* and *Victory* which will withstand the sun as well as the lighter sorts; here is another thing to try for. The blue *Gladiolus* is yet to be raised. Monsieur Lemoine has given us several beautiful and striking varieties which he modestly calls bluish, not blue. These are very fine under some conditions, but they are all Lemoinei varieties of the sparsely flowering section and a dash of rain reduces the flowers to a miserable state.

Of the different classes of *Gladiolus* I value the *Gandavensis* most highly. This strain has finer spikes and more varied colors than any other, as might be expected from the much longer time it has been in cultivation. The Lemoinei race, descended from *G. purpureo-auratus* crossed with *Gandavensis* varieties, seems to divide itself into two sections, much unlike each other, one having tall arching stems with few flowers, and those of the hooded shape peculiar to *G.*

*purpureo-auratus*, and with usually very vivid blotches on the lower petals; the other with flowers as open as the *Gandavensis* sorts, and in many cases not to be distinguished as of the Lemoinei strain, except by the slenderness or the curvature of the stalk, yet this section has a few kinds with straight, erect spikes of flowers almost equal to any *Gandavensis*, yet plainly showing their hybrid origin. The Nancianus class, raised between *G. Saundersi* and the Lemoinei varieties, is remarkable for the size and striking appearance of its flowers, but there is not enough variety in their hues and too few are open at once. As for the Childsi class (I call it so with reluctance), which has been raised from *G. Saundersi* and the *Gandavensis* class, I am compelled to say of it, as I have said before, it must be much improved before it will be worthy of cultivation. There are, it is true, a few very good kinds which were worth naming. I have three such, but the bulk of them are in no respect better than eighty per cent. of the seedlings which we raise by the thousand. There must be a great self-denial on the part of those who raise seedlings of this strain, or it will fall into the obscurity which has swallowed up that California strain of which we had such glowing accounts a few years ago. When I expressed a similar judgment as to the Childsi class last year I received some letters of remonstrance, but I must speak of them as I find them, fully convinced that they may be made a distinct and valuable class, but only by using great caution in dignifying the seedlings with names.

I mark such of my seedlings as seem worthy of farther trial by tying a label to the stalk pretty tightly, and I find that these stalks give me more seed than others. Has any one noticed the same occurrence? I have before mentioned that *Gladiolus Saundersi* is hardy here. The clump which has endured several years is now again in full flower, a dense tuft of foliage with nine flower-spikes three feet long pushing boldly up from the turf, and giving me more pleasure than the thousands which I labor over so much.

Canton, Mass.

W. E. Endicott.

## A New Double Hollyhock.

**A** GENERATION ago the single Hollyhock, *Althæa rosea*, was one of the commonest cultivated flowers, and its rose-colored blossoms were the most conspicuous decoration of many country dooryards. But the large plain flower, bold and stately though it was, failed after a time to satisfy the public taste. The ravages of the Hollyhock rust in Great Britain have prevented its being extensively grown there since the middle of this century. However, the dissemination of the more attractive double varieties in this country and the hope in England that the fungus pest has done its worst and can now be successfully combated, has reawakened interest in this old-time favorite.

The Hollyhock lends itself readily to the production of new varieties, and a large number are offered. There are now growing on the grounds of the Vermont Experiment Station, and were exhibited at the Vermont State Fair this fall, specimens of a new double variety originated by Mr. A. E. Wohlert, gardener to the Pennsylvania Railroad at Altoona, Pennsylvania. Several years ago Mr. Wohlert was in need of a flower for planting among shrubs which should make a good effect at a distance for a long period and yet look well near at hand. The common Hollyhocks were tried, and fulfilled the first requirement, but the blossom was too precise and geometrical when closely examined. Mr. Wohlert commenced breeding for a better style of flower by crossing selected specimens of a common single variety with *Chater's Best* and obtained a fringed, well-formed, semi-double flower. A seed sport from this was crossed with a large semi-double variety found growing in a farmer's dooryard, and produced a fine double strain, which Mr. Wohlert has introduced this year as the *Alleghany Hollyhock*.

The inner petals of the common double Hollyhocks make a compact mass of plain floral leaves all of the same length, but shorter than the true petals, which form only one whorl, as in the single varieties. On account of this arrangement and peculiar difference in the lengths of the petals there is produced an impression of disproportion between the heavy-appearing centre and the delicate wall. In this double Hollyhock the suggestion of formality and disproportion is absent, and the effect is more unconventional. For this reason it is more desirable for planting among shrubs. The reverted stamens are curled and fringed and not closely laid together. In the type they are of the same length as the petals, forming a large, full, well-rounded flower, light and graceful. The colors range through all gradations from pink to black-red.

The *Alleghany* is variable, and has already developed within

itself several different shapes. This marked variability is, of course, due in great measure to its newness, and persistent selection will do much to fix the variety. The most perfect flowers bear very few seeds, although those less perfectly doubled produce an abundance, and the strain would, therefore, be liable to deteriorate rapidly in the hands of inexperienced growers. This new form further shows a tendency each year to produce a few (ten per cent. or less) of single flowers and as many more of otherwise worthless ones. On account of its novel shape the Alleghany is a distinct and valuable addition to our already long list of Hollyhocks, while in delicacy of shades and tints it is surpassed by none.

University of Vermont.

V. A. Clark.

## Notes from Wellesley.

**A**MONG autumn flowers *Rudbeckia fulgida* shows up well in the borders. It is tall and stiff in habit and floriferous. The flowers, though smaller than those of our native *R. hirta*, are distinctly rayed, while the black centre makes a striking and pleasing contrast. It is a useful plant for cut flowers.

*Salvia splendens compacta* can only be kept true when raised from cuttings. The plants are now a mass of brilliant scarlet. Growing not more than one foot high, these *Salvias* make a better bedding plant than scarlet *Geraniums*.

An attractive bed in the flower garden on the estate of H. H. Hunnewell, Esq., is made up of trailing *Roses* of the *Wichuraiana* type, with the pretty *Nierembergia frutescens* intermixed. The *Roses* are beautiful in spring, and *Nierembergia* makes a display in summer.

A bed of Giant Grasses, with *Arundo Donax* fifteen feet high, tapered down with striped and barred *Eulalias*, some *Panicums*, and here and there a *Cyperus antiquorum*, is one of the most attractive features here just now.

*Cyperus alternifolius* and its variegated form make excellent pot-plants for table decorations. They sow themselves freely in our greenhouses and come up as an edging to the walks. They are equally effective as bedding plants in sub-tropical gardens.

Another common yet interesting plant is the Wandering Jew Saxifrage, *S. sarmentosa*. It is not hardy. It makes an excellent basket-plant, the stolons, with plantlets, drooping sometimes more than two feet. Under the greenhouse benches it takes care of itself, and when in bloom is quite effective with long spikes of white flowers.

The vigor of the popular autumn-flowering climber, *Clematis paniculata*, is now well known; it here grows twenty-five feet and covers a large Maltese cross with a mass of bloom. Seeds gathered when ripe, sown at once in boxes, left until frozen, and then covered with litter and kept so all winter, will germinate in spring.

Wellesley, Mass.

T. D. Hatfield.

*Rudbeckia* Golden Glow.

**W**E have been much pleased with this novelty this season (see GARDEN AND FOREST, vol. x., p. 294), and consider it altogether the finest herbaceous plant for border use sent out in recent years. It is quite distinct from *Helianthus multiflorus* in that it flowers fully a month earlier and is past when the latter begins. The long-stemmed flowers are useful for cutting, and are smooth-stemmed and not so unpleasant to handle as those of the *Helianthus*. It is also perfectly hardy, a strong point in its favor, as the *Helianthus multiflorus* cannot be relied upon every year and often winter-kills, so that it needs protection to make sure of it. The variety Golden Glow appears to be a form of *Rudbeckia laciniata*, a rather weedy plant and suitable only for semi-wild situations. This double form is free from the objectionable weediness and its only fault is in the weakness of its stems, which it is necessary to stake when the flower-buds begin to form. Otherwise it is an ideal plant for the border.

South Lancaster, Mass.

E. O. Orpet.

**Lilium Henryi.**—It is a surprise as well as a pleasure to note the praise that has been bestowed upon *Lilium Henryi* in recent garden literature. After having seen it in blossom for two years in Mr. Horsford's gardens at Charlotte, Vermont, I am willing to believe all the good reports of it. The plant seems to be remarkably hardy, thrifty, vigorous and free from disease. The individual flowers are beautiful, but the general effect of several plants growing together is truly magnificent. There is a free and easy unconventionality about such a group which reminds one of *L. speciosum rubrum* at its best. *L. Henryi* is more pleasing, and it is, perhaps, not too much to

say that for the hardy border, thrift and beauty considered, this species surpasses all others known to cultivation.

University of Vermont.

F. A. Waugh.

## Correspondence.

## The Botanic Garden of the Michigan Agricultural College.

To the Editor of GARDEN AND FOREST:

Sir,—Michigan Agricultural College has a campus of about eighty acres, besides the orchards, fields, vegetable gardens and forests, and three acres are devoted to growing hardy plants in what is called a botanic garden. Here 1,850 species are now under cultivation. The botanic garden is well kept, and that it is interesting is attested by the many visitors of all classes during the growing season. Granges, farmers' clubs, Sunday schools, lodges, entire schools with their teachers, professors of colleges, and students taking a vacation trip on bicycles, all visit this botanic garden. It is none the less interesting because it differs so much from the parks usually found in cities, and contains no "bedding plants." The interest shown by visitors encourages us to believe that the effort to plant and maintain a small botanic garden is worth a good deal more than it costs.

Everything considered, from early spring into late autumn, the Mint family is one of the most satisfactory to cultivate and one of the most attractive to visitors. Nearly all the species of Mints in our garden, some sixty-five in number, are placed in one group. Large dense masses of plants, with tops of an even height, are pleasing to most persons. The shape of leaf and the color sometimes attract attention, but the general shape of the plant strikes people as important. Of this family we have Linden-leaved Sage, *Salvia tiliaefolia*, an annual from Europe. The mass is dense and even, and three feet or more high. It always wins notice; notwithstanding the flowers are small and inconspicuous. Another low annual known as American Pennyroyal, *Hedeoma pulegioides*, is interesting when well grown. It is easily kept from year to year on sandy land, not too dry, and a patch three to four feet in diameter is satisfying to the eye. The odor is remarkable and usually pleasing. A dense and thrifty patch of Thyme, five feet across at this season, attracts insects in large numbers by its spikes of small light pink flowers and its delightful fragrance. In 1893, while attending the World's Fair, I made the acquaintance of an attractive plant on the prairies and took specimens of it to plant in the garden here. It is thrifty from spring to October, and it deserves more general cultivation than it has yet received. This plant is False Dragon-head, *Physostegia Virginiana*, one of the Mints. I planted it in sandy land, not far down to water. The leaves are thick, very dark green, lanceolate, strongly denticulate; the plants five to six feet high. To be appreciated there should be a good clump of it, and not only a few stems. In central Michigan it flowers late in August and early in September. The dense spikes are three to eight inches long; the flowers all bend to one side, are of a light rosy hue, an inch long and somewhat trumpet-shaped. The spikes are liable to fall over unless grown in a still place or tied to stakes.

In rich, moist black earth at the foot of a low bank under the spreading limbs of evergreen trees, we have a spot well adapted to Ferns and some other choice plants. Near by a group of *Ginseng* develops to perfection, and just now the umbels of shiny vermilion berries are at their best, and the leaves are beginning to show a tint of the same color. White Baneberry is displaying fruit to good advantage, the white berries on thick red pedicels, each berry turning up a small black eye. Here is also a thrifty patch of Yellow Puccoon, *Hydrastis Canadensis*, four by eight feet, from which large crimson berries have lately been removed. Physicians are always glad to look at it and frequently ask for seeds or roots, the latter of which bud at random in sufficient profusion to multiply the species. The healthy plants are attractive in the shape and color of the leaves and in the color of the berries. Near by are two masses of *Hepatica*, three to four feet across, one of each of our two species. They are still in perfect health, with all the leaves fresh and sound and give promise of a splendid crop of their flowers in early spring. Considerable pains have been taken by our students in contributing individual plants distinguished for flowers of different sizes and colors from white to pink and dark blue.

Three or four years ago I introduced from the south some plants of the Water-lily family, known as *Cabomba Caroliniana*. These were placed in two ponds, but until this year they escaped notice. One mass is now twelve feet in diameter.

The flowers are small and white, but the stems with their bright green dissected leaves are two inches in diameter and have a striking appearance. Nothing in the garden is more admired by visitors of all classes than two large masses of the pink Water-lily from Cape Cod.

For late summer and autumn I commend *Polygonum Virginianum*, familiar in moist thickets. The ovate or lanceolate leaves when grown in the open are dark green, with a velvety appearance. The plants are about four feet high, including the slender spikes, which are from twelve to twenty inches long. Our compound plant is eight feet in diameter. In the woods the leaves are lighter and the calyx is green, but when exposed to the sun the calyx is crimson. The long, slender and naked spikes are rather rigid, and with the persistent crimson calyx, all above the leaves, make a striking picture. The botanist is interested in the plant for its plan of distributing its seeds. Each flower-stalk has a joint at the base, where it separates very easily when mature. It dries with a tension, so that if touched the fruit goes off several feet with a snap and a bound. The wind or some passing animal shakes the elastic stems, jostling them against each other, and thereby sows the seeds broadcast. The two slender, stout, persistent styles are recurved at the apex, and catch on convenient objects like a burr. Should there be a freshet the seeds, enclosed by ovary and calyx, will float with the sticks and leaves. Besides its beauty of form and color, its other peculiarities make it an attractive plant, and yet no one has thought enough of this hardy perennial to give it a common name. It is nearly allied to Prince's-feather, and is more interesting than that plant. Growing next to it, and belonging to the same genus, is *P. arifolium*, Halberd-leaved Tear-thumb. This is a neat annual, not pleasant to handle, but interesting as it is seen climbing over bushes and holding on by its recurved hooks. The heads of small white flowers are not gaudy, but they are well placed on long stems above the dark green leaves.

In damp summers the native Wild Balsam-apple, *Echinocystis lobata*, plays a conspicuous part along the river-bank among the bushes. It rambles about, sometimes covering almost everything for a space of forty feet and stands ten to twenty feet above the ground. In such places it is peculiarly attractive at this season. I have recently introduced and planted near this species the One-seeded Bur Cucumber, *Sicyos angulatus*. These plants ramble over and under each other in a surprising fashion, sometimes one having the advantage and sometimes the other. Last year the Balsam-apple was the more prominent; this year I think the Bur Cucumber is ahead.

The deep blue flowers of Wild Comfrey, *Cynoglossum Virginicum*, are pleasing, and resemble a large Forget-me-not, with flower-axis somewhat drawn out.

In a low secluded spot exposed to the sun Castor-oil plants grow ten to fourteen feet high, with stems nearly as large as one's wrist. While the flowers are interesting, these are not as attractive to the general visitor as the great tropical-looking leaves.

South of an exposed bank I had twenty to thirty loads of sand drawn in from the flats of the river and have had it fertilized a little. Here a mixture of plants is grown which thrive in such soil, including Lupines, three species of *Ceanothus*, hardy Cacti, Bearberry, Sand Cherry and many others. Among the favorites are *Solidago rigida* and *Helianthus occidentalis*, which several times failed under seemingly better treatment. *Tanacetum Huronense*, from the sandy shores of the Great Lakes, makes itself at home and strives for more space than we are willing to allow. The bunches of large yellow heads of this Tansy above the healthy feathery leaves are worth inspection. And here *Desmodium rotundifolium* rambles in great perfection, the prostrate vine overhanging some boulders. Its round leaflets always attract attention, while the light pink flowers and peculiar fruit help to give variety.

Lobelias are grown in an artificial depression where they can be flooded when necessary. The bright blues and the cardinal flowers are well known. For a few weeks in September the wide row of several species of *Hibiscus* is at its best.

Agricultural College, Mich.

W. J. Beal.

#### Notes from Rochester, New York.

To the Editor of GARDEN AND FOREST:

Sir,—There is always a scarcity of flowering shrubs at this time of year, and, indeed, the flowers of perennial herbaceous plants are not too plentiful in the border at this season, and any additions are welcome.

It was a surprise to see in Highland Park, at Rochester, New

York, some very fine specimens of *Vitex Agnus-castus* in full bloom. Mr. Dunbar stated that the plants were not hardy and had been killed down to the ground each year. The resulting growth gave them the appearance of being herbaceous instead of shrubby plants. The long spikes of bright lavender-blue flowers were extremely ornamental and distinct. *V. Agnus-castus* and *V. incisa* are the species grown there, the latter being the inferior in point of color, but both are desirable where a collection is grown. This plant will probably prove hardy enough in a moderately dry soil in all of the eastern states, as the winters at Rochester are more severe than in Massachusetts, and much difficulty is found there with evergreens that ordinarily are quite reliable here. It was surprising to see many plants of doubtful hardiness thriving there, and I was shown a vigorous young plant of *Sequoia gigantea* that had survived the past winter without protection and which had grown nearly two feet this summer.

The English Broom, *Genista scoparia*, has also been successfully grown there for a number of years, long enough to form a handsome bush, and at this time is covered with seed-pods after a fine display of bloom. It would be interesting to see if the variety *Andreanus* will prove hardy there also. This is only a form of *G. scoparia*, but it comes from the hills of Normandy, where it appeared as a sport among the common Broom, and, unfortunately, has not proved as hardy as the type, if the latter is taken from a British-grown plant. It is well known that geographical forms of the same species have varying degrees of hardiness, and while we hope Mr. Dunbar may succeed in acclimating the variety *Andreanus*, this is doubtful. A plant of this species tried here, and which was well established on its own roots, did not survive the first winter.

There is much of horticultural interest in Rochester in its many large and famous nurseries, and the fine system of parks that has recently been formed is already a credit to the city. This system includes the Genesee River Gorge, a feature unique in its way and of inestimable value for its magnificent scenery, and the gorge has been made secure to the public for all time; the South Park, with its broad pastoral views; and the more highly developed Highland Park, where it has been the object to have every species of deciduous shrub that will grow planted according to its botanical affinity. This has been accomplished in a most happy manner on sloping hillsides that prevent monotony and give easy access by grassy walks.

So. Lancaster, Mass.

E. O. Orpet.

#### Peaches in the Ozark Mountains.

To the Editor of GARDEN AND FOREST:

Sir,—The big packing tent in an Ozark orchard of Elberta peaches is a lively and interesting place. Through the centre of it runs a long table, at each side of which the packers, who are all women, sit on boxes set on end. Men in a straggling line pass out, going with empty cloth-lined baskets, and return them filled with richly-colored fruit. There is a general foreman, who is responsible for the picking, packing, shipping and marketing, an under foreman, known locally as a "straw boss," to every six pickers, and a forewoman for the women packers, of whom there are as many as forty in the busy season. So-called "lackeys," men and boys, keep the packers supplied with fruit, baskets or boxes and wrapping paper, and remove the filled packages from the table. In the tent an efficient forewoman is in authority, and moves about the table with her eyes on every worker, while her constant admonitions and directions suggest new ideas to the consumer, who, after much experience in emptying such packages, sees them for the first time being filled. The forewoman decides what sort of packages shall be used for the fruit which is then being picked. The finest grade is packed in "California" boxes, the next in six-basket crates, and the lower grades in four-basket crates, and "thirds," the familiar peach boxes that hold one-third of a bushel. With her cry of "All thirds," "Californias," etc., as the case may be, the empty packages are set within reach, the women at once begin to handle the fruit, and the watchful forewoman is fluent in a series of remarks, as, "handle them fast, girls," "just as fast as you can," "remember! the long way of the peach, the long way of the box, and the blush side up every time," etc.; but "blush up every time" is most frequently repeated. And the workers, too, have their say. The eight and one-half inch square white papers rustle and crumple under the swiftly moving hands, and the cries of "peaches out of the way" and "more peaches," or "peaches off" and "peaches on," come in rapid succession. Handsome sprays of peach-leaves are laid on the top of all the packages by boys. Men then fasten

on the lids, others stamp the boxes and crates containing the highest grade, Fancy Elbertas, or Fancy Freestones, and those holding the next grade, Choice Elbertas, or Choice Freestones. The crates are carefully loaded into the high-boxed peach wagons and driven slowly to the shipping shed at the railroad siding. During the rush in the Elberta season two refrigerator cars were dropped at the railroad station of the Olden fruit farm every day. As soon as enough crates to fill a car are piled on the platform they are deftly and rapidly packed in the car, each box or crate being isolated by using inch-square cleats horizontally and one and a half inch cleats vertically between the packages, so that the cold air circulates freely around every package. Four tons of ice are used in icing a combination refrigerator ventilator-car. A fruit express train picked up the cars every evening from near the Arkansas line to Cedar Gap, making passenger time from that point to Kansas City.

Brighton, Ill.

Fanny Copley Seavey.

### The Dikeman Cherry.

To the Editor of GARDEN AND FOREST:

Sir,—Referring to your note about the Dikeman Cherry, on page 338, and which I saw as one of the judges at the New York State Fair, this new variety seems to meet all the requirements of a good late cherry that will bear shipping, and does not decay. The cherries at the State Fair had been picked on Friday, August 20th, in Michigan, and shipped nearly 500 miles by express to Geneva, New York, then sent to Syracuse and put on exhibition. They were in sound and fresh condition, and I may add that on Saturday, August 28th, I brought some of the fruit home with me that had been on the plates during the whole week, and it is now, August 30th, on my table perfectly sound after all this exposure.

The Dikeman is a beautiful solid, meaty, black cherry of the best quality. Taking these characteristics with its lateness and shipping and keeping qualities, it is the most promising cherry of which I know, and Mr. Willard is to be congratulated on securing so valuable a prize. Mr. Willard found the cherry growing in the light sandy soil of Oceana County, Michigan, a short distance from the lake, the tree presumably a seedling. A few buds were secured, and these were top-budded on some bearing trees in Mr. Willard's orchard at Geneva, and from these a few trees have been grown.

I might also mention the President Wilder currant, of which a remarkable exhibition was made at this fair by Mr. Willard. The fruit was large, clusters long and filled to the end with beautiful berries which maintained their size along the entire cluster. The fruit is of first quality and as large as that of the Cherry currant, more juicy and with less seeds and acid than any other variety of which I know. The leaves are thick and large, the wood strong and loaded with an immense amount of fruit. All these qualities must make it a popular and profitable market currant.

### Crested Begonias.

To the Editor of GARDEN AND FOREST:

Sir,—An error in punctuation in my note on Crested Begonias, September 8th, page 353, unfortunately confused the description. It should read: "But sometimes attached to all the petals, and sometimes only to either the inner or outer pair, a growth springs from the lower section, though not from base of petals."

I might add that this growth is of the same texture and color as the petals, but is not in the nature of a doubling of parts. It seems to be simply a sportive growth in an entirely new direction.

Elizabeth, N. J.

J. N. Gerard.

### The Cheney Plum.

To the Editor of GARDEN AND FOREST:

Sir,—In writing to GARDEN AND FOREST some weeks ago regarding the ornamental value of Plum-trees I made special mention of the variety propagated under the name of Cheney. I have just now received some very fine specimens of the fruit of this variety from Mr. John Craig, of the Central Experimental Farms, Ottawa, Ontario. Though not so notably prolific as some American varieties, Cheney bears fruit of a very superior quality and appearance. Those sent by Mr. Craig are somewhat unequally elliptical, with a longitudinal diameter of 3.5 cm., and a transverse diameter of 3.1 cm., with a visible suture; bright dark red, with a very thin white

bloom, almost without dots; skin thick and firm; flesh firm yellow, of fine quality; stone medium large, much flattened, cling. As stated in my former communication, the tree is a fine grower, and especially pretty in blossom. Professor Bailey rates the fruit as good to very good, and says that this is one of the best varieties. It seems to me to be a very satisfactory example of the Nigra group of native plums—a group very poorly represented in cultivated varieties as compared with the western type of *Prunus Americana*. It is, therefore, interesting as a type besides being useful as an ornamental and as a fruit tree.

### Recent Publications.

*Our Native Birds of Song and Beauty.* By Henry Nehrling. Vol. II. George Brumder, Milwaukee, 1896.

The first volume of this work was noticed in our issue of April 18th, 1894, vol. vii., p. 159. The present and concluding volume was completed early this year. It may be fairly said that the aim of the undertaking, the filling of a gap between the very expensive and the merely technical books on our ornithology and the combination of popular biographies of our song birds with the presentation of recognizable portraits of them, has been successfully attained with a result that must be useful to a large class of readers. The author has added to his own observations made during residence and travel in various parts of the country copious quotations from the best writers on the subject, and this feature adds much to the value of the book by putting the general reader in possession of a great deal of interesting matter he would not be likely to meet with otherwise. All technicalities have been carefully avoided, the specific descriptions being appended in smaller type. Interspersed throughout is much information about plants, wild and cultivated, with both of which the author is well acquainted, and the descriptions of scenery in various parts of the country show him to be a true lover of Nature.

The plates, printed in colors from drawings by Ridgway, Goering and Muetzel, vary considerably in style and quality, those of the German artists being overcrowded with figures and overloaded with heavy backgrounds. Landscapes, as a rule, do not add to the beauty of ornithological plates, and the simpler the accessories the better. The figures of the birds are generally well drawn and lifelike, and would, in our judgment, look better without such elaborate surroundings. It would have been better, too, to have preserved a more uniform scale in the size of the figures. In the matter of typography the red-lining of the page is not to our taste, but in other respects the work is well printed. The popular interest in ornithology has become so general in this country that a work like the present cannot fail of large usefulness.

*Contributions from the United States National Museum,* vol. v., No. 3: Studies of Mexican and Central American Plants. By J. N. Rose.

In this very interesting number of the *Contributions* Dr. Rose has given the result of his careful studies not only of the later collections from Mexico and Central America, but of many of the older ones necessarily compared with them. The plan of reporting on separate collections is abandoned in view of the large number of sources from which the plants have been received. The present plan of working up the various collections jointly and reporting upon them by genera or families, with at times revisions and synopses, seems justified by the great body of material at hand, and we think the result before us will be heartily endorsed. Such synopses as those of *Heliocarpus* and *Wimmeria* will be found very useful and suggestive, and the work in family *Cucurbitaceæ* shows the excellent judgment that characterizes all of Dr. Rose's revisions.

The large number of plates is a feature, seventeen of them being given to the thirty-four pages of text. They are as satisfactory as any that have been published in the series.

## Notes.

Messrs. Ellwanger & Barry on the 4th of September shipped a collection of 125 varieties of pears from the Mount Hope Nurseries, Rochester, New York, to the Horticultural Exhibition at Hamburg, Germany.

American readers of *The Garden* will be interested in the colored plate of *Lathyrus splendens* in a recent issue of that journal. This perennial Pea, native of southern California, flowered at Kew for the first time this year, and for three months there was a continuous display of the beautiful rich red-maroon blossoms.

In the fancy-fruit stores, among choice and handsome offerings, are luscious Kelsey plums with honey-like flavor and large nectarines from the Pacific coast; spicy muskmelons from Rocky Ford, Colorado; new-crop lemons from Florida; so-called Valencia oranges, from California, held over in cold storage; Prickly Pears, the fruits of *Opuntia Tuna*, from the Mediterranean, and the first winter melons, from fields near Naples.

Since the time of the Pharaohs lime has been used in European countries in agriculture, and perhaps more experiments have been made with this substance in connection with plant growth than any other chemical. A condensed summary on the practice of liming has just been published by the Rhode Island Experiment Station, which gives in a brief compass some essential facts that every agriculturist ought to know, and we commend this little treatise of a score of pages to the careful attention of every student of agricultural science.

An instructive circular has just been published by the Division of Forestry, relating to the age of trees and the time of blazing them as determined by annual rings. The difference of the layers of spring wood and summer wood in coniferous trees, as well as the structure of ring-porous woods like the Hickory and Locust, is explained so that the careful student receives all needed directions in making his investigations. The circular covers less than a dozen pages, but it is so carefully illustrated and prepared that no novice can read it carefully without receiving genuine instruction.

Mr. Joseph Meehan recommends *Pueraria* (*Dolichos*) *Thunbergiana* for a trellis on the veranda. The best opportunity is thus afforded to train this vine so that its fragrant rose-colored flowers are not hidden under the luxuriant foliage. The perennial *Plumbago* *Larpenæ* is now showing its blue flowers in Germantown, where it is sometimes at its best during October. Mr. Meehan calls attention to the advantage of cutting off the flower-heads of *Spiræa* *Bumalda* in July when the first blooming season is past. With this attention this plant is now flowering as profusely as early in the season, though the flower-heads are not as large, and its season may be indefinitely prolonged.

Mr. J. G. Jack will conduct a series of lectures and field meetings at the Arnold Arboretum, beginning September 18th and closing November 6th, for the purpose of supplying popular instruction about trees and shrubs which grow in New England. The intention is to indicate by comparison the easiest means of distinguishing the common native trees and shrubs and to recognize foreign species which have been introduced into gardens. The ornamental and useful properties of these trees and shrubs, their habits of growth and other peculiarities will be considered, and particular attention will be given to their identification and general aspect as they lose their leaves and prepare for winter. The classes will meet on Saturday mornings at ten o'clock and on Wednesday afternoons at three. Applications or inquiries may be addressed to Mr. J. G. Jack, Jamaica Plains, Massachusetts.

Professor Plumb has recently followed the example set by many other American students of Agriculture and visited Rothamsted, the scene of the great series of experiments which have been persistently carried on for more than half a century in order to ascertain some trustworthy data in regard to the exhaustion of plant-food from the soil. Interesting as is this estate, it is very plain that Sir John himself will continue to be the crowning attraction of Rothamsted as long as he lives. He wears his eighty-three years like a man of middle age and tramps his fields as sturdily as if he were no more than thirty-five. Sir Henry Gilbert, his companion for more than fifty years, and who has been helping Sir John carry out his experiments, is an equally well preserved example of English country life, and every civilized man who takes an interest in agriculture will unite with Professor Plumb in wishing to these

eminent Englishmen many and fruitful years to their generous work.

Professor J. B. Smith, of the New Jersey Agricultural Experiment Station, has sent out a circular in relation to the San José scale, which briefly advises that all infested bearing Apple, Pear, Plum and Peach trees should be sprayed thoroughly in September with undiluted kerosene in the middle of a clear, sunshiny day. By undiluted kerosene is meant the ordinary burning fluid used in lamps exactly in the condition in which it is purchased, and it should be applied in the finest possible spray, so that every part of the plant should be wet thoroughly, but no more. One application is sufficient, and it may be delayed until the fruit has been removed, although the sooner it is now applied the better it will be. The treating of nursery stock or of very young trees in this way with undiluted kerosene is not now recommended. The details of the experiments upon which this treatment is based will be reserved for the close of the season, but Professor Smith sends out this circular so that something may yet be done before the year closes.

The problem of food supplies for two million persons crowded on a limited area is an interesting one, and the buyer of choice products at high prices need not have philanthropic impulses to wonder occasionally how the majority of the city's population is fed. Of a half dozen characteristic markets for the masses scattered through New York City, one of the best known is "Paddy's Market," held each Saturday from the middle of the afternoon until eleven o'clock at night, on Ninth Avenue from Thirty-eighth to Forty-second Streets. In the evening these four blocks are a scene of surprising animation. On both sides of the wide avenue wagons are drawn up lengthwise along the curb, the horses headed toward the middle of the street, with push-trays, barrels and crates crowded in, and all heaped with offerings. Much space is also occupied on the sidewalk along the fronts of the stores. The stock is arranged with considerable neatness, and in some instances the open wagons are entirely lined with heavy white paper. Often a wagon holds but one kind of fruit or vegetable, though an assortment is sometimes offered. Many flaring torches on the wagons add a weird brightness to the city's electric lights. The rumble of elevated trains overhead and the noise of street cars almost escape notice in the harsh guttural and nasal shouts of venders. A wagon-load of onions may have for its neighbor a wagon-load of peaches, or melons, corn, cabbage, celery, plums, beans, apples, bananas, cucumbers, potatoes, pears, chickens, hams or fish, not taking into account household utensils, shoes and clothing. On a hot night lemons are abundant and sell at five cents a dozen. Among vegetables, string-beans now seem most in demand. Pails are the ordinary and enticing form of measurement and hold from one to four quarts. A small pailful of beans sells for five cents early in the evening, and later on overstocked dealers look for buyers at three cents. Boys mingle among the throngs on the sidewalks and offer heaped pails of vegetables and fruits for a few pennies. Women stand at the street corners with large baskets containing eggs, and in each instance a candle, and make a show of testing the eggs by its light, at the same time keeping an eye on mischievous lads in the crowd who watch the chance to shy a pebble into the fragile collection. English is heard almost entirely, though there are some Polish and Italian sellers. The orderly crowds of buyers are mostly Irish, Italians and negroes. The purchases are carried away in arm-loads of brown paper parcels, in paper and muslin sacks, and in capacious baskets with dome-like lids, and occasionally aprons hold an overflow, while, as the evening progresses, half-bushel baskets of peaches prove an irresistible bargain to thrifty housewives who struggle along with them. A particularly fragrant stand has a collection of fresh herbs from a suburban garden and the woods about Fort Lee. Large Mullein leaves, plants of Dandelion and stalks of Boneset, Horehound and Tansy are confidently recommended as remedies and sold in generous bunches at five cents each; Mint is said to drive away ants, and Pennyroyal is sold to hang in open windows and keep away the mosquito plague of this wet summer. Policemen seem even unusually scarce here, and from the two hurriedly questioned it was learned that while this market has been carried on during considerably more than a quarter of a century, it has only been organized within the past three or four years. The licensed dealers pay a small tax for the space occupied and share in the cost of promptly clearing away the waste. Only rare and choice fruits and vegetables are missing here. The quality is fair for this class of market, with almost no really unwholesome stock, and the low prices put substantial meals within the reach of persons of very small means.

The Massachusetts Trustees of Public Reservations.

THE work of the Trustees of Public Reservations in Massachusetts continues to maintain the important and interesting character that has distinguished it from the start, six years ago. This public-spirited corporation furnishes a striking instance of what can be accomplished by furnishing a nucleus for the aspirations and the efforts of those who have at heart any special line of action for the common good. In such work the greatest factor, perhaps, is the obtaining of an adequate leverage from which things can be moved. The Trustees of Public Reservations have supplied such a leverage for the lovers of "beautiful and historic places," to quote the happy phrase with which the late Charles Eliot expressed the aim of the movement at its inception. The corporation has done little more than furnish this leverage; the friends of its work have done the rest.

The Massachusetts trustees are the pioneer body in their peculiar line of activity, and their example has been successfully followed in other parts of the world. For instance, when the work of the Massachusetts corporation became known in England, it was felt that this was just the sort of instrumentality for the accomplishment of a much-needed work there, and the result was the organization of an influential society with similar aims, called the National Trust for Places of Historic Interest or Natural Beauty. On this side of the ocean the Appalachian Mountain Club, of Boston, has been endowed by legislative enactment with similar functions; the desirability of action for the preservation of notable features of mountain scenery in New Hampshire led to this step, and the club, therefore, as a rule, pursues its activities in this line outside of Massachusetts, where the work of the Trustees of Public Reservations amply covers the ground. In other parts of this country organizations have been formed on lines similar to those of the Massachusetts corporation, and good results are reported from them.

The work of the Trustees of Public Reservations in Massachusetts has been of two kinds—suggestive and administrative. Although composed chiefly of persons of means and influence, the corporation has no large funds directly at command. But when work of an incentive

character has seemed desirable the necessary means have been forthcoming, and the supplying of needed funds has been an essential preliminary for the undertaking of any special piece of administrative work. Its work of incentive, or for purposes of public information, has been particularly desirable. Of this kind were the notable investigations concerning the public open spaces in the shore towns of Massachusetts which the trustees caused Mr. J. B. Harrison to make, the results of which were first made public in the pages of GARDEN AND FOREST; also the full and accurate statistics concerning public open spaces in the cities and towns of Massachusetts contained in the second annual report of the trustees; and finally, the report on the open spaces in the shore towns made by Mr. H. B. Hastings, supplementary to the work of Mr. Harrison, given in the third annual report.

It is largely due to the incentive of this corporation that the legislation was obtained instituting the Boston Metropolitan Park Commission, whose work is transforming the country about the New England metropolis into scenes of remarkable and enduring beauty. And when the vexed question of the Province lands at the extreme end of Cape Cod came up for consideration the Trustees of Public Reservations were selected by the Massachusetts Legislature to investigate and report upon the subject. In consequence, after a controversy of nearly two centuries, the residents of the greater part of Provincetown were for the first time given full title to their holdings and a scientific policy was adopted for the administration of the many hundreds of acres of state lands there, including the reforesting of the great sand-dunes that were threatening the town and the harbor with ruin.

Invaluable information has been given by the investigation, under the auspices of the trustees, of the public's rights upon the seashore. There are other lines of investigation which might profitably be entered upon, such, for example, as the rights of the public in small streams and in ponds; any young student interested in these lines of research might do real public service by bringing to light the various curious and instructive provisions concerning such matters contained in the old colonial and provincial laws. The Trustees of Public Reservations would doubtless supply the medium of expression for any investigations along these lines.

For a while it seemed as if there would be little administrative work for the trustees. But, as time has passed, various opportunities for usefulness in this direction have presented themselves, and it is probable that before long the holdings of the corporation will be scattered throughout the commonwealth. The procedure in these matters is simple, and entails but slight burden upon the standing committee of the trustees, upon which rest the active functions of the corporation. When investigation shows the desirability of preserving any beautiful or historic spot in any portion of the commonwealth the trustees assume the charge thereof on condition that the funds necessary to maintenance be provided. Thereupon regulations for the proper use of the place are adopted and its care is given into suitable local hands. Virginia Wood in Stoneham was the first gift to the public placed in charge of the trustees. This has become an integral part of the great metropolitan reservation of Middlesex Fells, and therefore requires but little direct oversight from the trustees. A bronze tablet, inscribed with the facts concerning the gift, has been affixed to a ledge in the woods. Goodwill Park, in Falmouth, was given into the hands of the trustees for the benefit of the people of that town by Mr. Joseph Story Fay, and it has been placed in immediate charge of a local committee.

This year a particularly charming piece of property has been given into the keeping of the trustees by Mr. Augustus Hemenway, of the Metropolitan Park Commission, who takes an active interest in the preservation of beautiful scenery. A feature of Charles River landscape, second in picturesqueness only to Hemlock Gorge, will thus be

preserved for all time. Between the townships of Medfield and Sherborn there is a place where the narrow stream flows between a bank of woods and a high Hemlock knoll; behind this knoll lies a sunny meadow, bordered by more high woods. "Locally," says the recent report of the trustees, "the little gorge is known as Rocky Narrows, and the little meadow as the Dingle Hole; but many canoe men from the neighborhood of Boston know the place as the Gate of the Charles." The eastern bank of the river at this point is the property of the commonwealth, being a part of the grounds of the State Asylum at Medfield, and the area on the western bank that has been conveyed to the trustees comprises about twenty acres.

The committee notes that much of the most charming and most easily destroyed scenery of Massachusetts is found along the banks of ponds and streams, and it is represented that it would be for public advantage if narrow strips of such waterside lands could be secured by interested and generous citizens and given into the charge of the trustees. "Many such strips are found between country roads and streams or ponds, and many other strips of similarly useless but beautiful land are to be found bordering roads in rocky or steep places. Nothing could more directly help to keep the state a pleasant and beautiful place to live in than such preserving of the local roadside scenery. Such strips, as well as hilltops, ravines, bits of seashore, and any remarkably beautiful spots will always gladly be taken charge of by this Board, provided some little money to form a maintenance fund comes with each gift."

It is remarked that other worthy objects for enthusiastic generosity are places of antiquarian, historic or literary interest; for example, visible traces of Indian villages and earthworks of the Indian wars, and the homes of eminent persons. There are also places of more strictly scientific interest which ought to be permanently preserved; a few remarkable botanical localities, for instance, such as *Rhododendron* or *Holly* thickets, and a few places of extraordinary interest to geologists. In the matter of local pleasure-grounds where it may be impracticable to establish regular park commissions—as in the case of Goodwill Park, in Falmouth—the Trustees of Public Reservations form a particularly desirable organization for their care.

#### The Swamps of South-eastern Missouri.

THE botanist familiar with the sphagnum bogs of the Lake region and the east is sadly disappointed in his first botanizing in the south-west at finding nothing comparable with them. In their place he finds muddy sloughs in the river bottoms, and even more muddy ponds, more or less dried out, representing the site of abandoned brickyards in the clay regions. Now and then, too, the springy margin of an artificial fish pond comes in for exploration. In such places, which at first seem quite unpromising, and the exploration of which is far less pleasant than that of the clean swamps of the north, are found, nevertheless, many plants which affect the eastern bogs; and while *Sarracenia* and the swamp *Ericaceæ* are not met with, they are replaced by plants which form equally desirable additions to the herbarium, though they may not afford equal pleasure in the collecting.

But to the eastern botanist, few localities offer a charm of novelty equal to that afforded by the deep swamps of Missouri and Arkansas, lying in general along the region of Crowley's Ridge. Remnants of the ancient delta of the Mississippi River, these swamps are everywhere traversed by streams, the sluggish flow of which has seemingly more than once changed its directions, while even to-day a flood period like that of last spring causes the backwater of the Mississippi and its larger western tributaries to more or less overcome their limits. This is the land of cotton, and while corn is here king, no inconsiderable amount of good fiber is shipped out each fall and winter.

A little further to the north and west, in the hill country,

the short-leaved Yellow Pine (*Pinus echinata*) is abundant, and one lone tree far down on the lowlands of Dunklin county suggests speculation concerning the earlier range of the species; but the lumber cut here is Cypress (*Taxodium*), Black Gum (*Nyssa sylvatica*), Cottonwood (*Populus deltoidea*), now coming into considerable use for cheap boxes, and the various White Oaks, chiefly for railroad ties. Of the latter, the true White Oak (*Quercus alba*) is perhaps the most abundant on the higher ground, but in the lowlands the Cow Oak (*Q. Michauxii*) is abundant, and often of very large size, and—a surprise to one who knows the Post-Oak barrens of the Ozarks—the Post-Oak (*Q. minor*) is almost equally common. Perhaps nowhere else in the United States is there to-day so large a supply of White Hickory (*Hicoria ovata*) as in this region; and in the rich damp woods below Delta from one hundred to one hundred and fifty feet represents the prevailing height of this species, the Texan Oak (*Q. Texana*), Sweet or White Gum (*Liquidambar*), and their associates. Here, too, *Salix nigra*, the Water Oak (*Quercus nigra*), and the Turkey Oak (*Q. digitata*) reach a great size.

The deep Cypress swamps lying along the streams, however, are the most remarkable in their interest. Except in seasons of great flood, the water of these sunken lands varies little in its general level, and the Cypress knees correspond approximately in height with this level for many miles, rising so close together between the trees that only a native can find passageway between them for a dug-out canoe. In such a canoe, with an experienced guide, barring the discomfort of the tailor's seat which must often be affected, one can pass with pleasure for hours silently between the trees, now startling a great turtle into a quick plunge from its sunning place on an emergent log, or in turn be startled by the quick call and splashing flight of a pair of mallards, and again recoiling as one's elbow almost brushes against a large water snake—a water moccasin, as it is here called—lying afloat on a snag; drinkable the water scarcely is, but it lacks the turbidity of the larger streams, and, stellate with *Cabomba* and *Jussiaea*, and often for miles carpeted with a dense layer of beautiful *Azolla* with intermingled *Lemna*, *Spirodela*, *Wolffia* and *Wolffiella*, it presents a delightful appearance not soon to be forgotten. But the novice who dips into it, or the botanist whose zeal leads him to gather its choice surface coating with incautious hand, is quite likely to learn that in the latter are certain small hemiptera, whose pungent thrust is no less painful than the sting of a hornet, though happily not so serious or lasting in its effects.

Here the *Nelumbium* is at home, and in season its great dew-studded leaves, with the curious bronzed lens of their lower surface conspicuous in the slanting light, and charming creamy flowers, form an almost impenetrable jungle in the waterway. But most marvelous of all are the masses of *Polygonum*, which, rooted perhaps ten or fifteen feet below the surface, finally emerge making a tangle on which, in hip-boots, one may wade with as great security as on the more solid land.

The trees of the deeper water are chiefly Cypress (*Taxodium*) and Tupelo (*Nyssa aquatica*), the greatly dilated bases of which rival anything of the kind that I have ever seen. Not infrequently within the hollow trunk of some old tree may be seen a perfect forest of young knees from its younger neighbors or even from its own roots, providing the aëration which these would otherwise never get in this region of perpetual water. Now and then old Cypress stubs, with gray bark and large branches emerging from the giant trunks close to the water level, stand in marked contrast with the tall, clean stems of a later generation, suggesting the doubtful hypothesis that the strip of land on which they grew has sunken locally below the general level of the stream.

Elsewhere, one finds *Amorpha fruticosa* and *Itea Virginica* as terrestrial plants, and indeed they are so found here in places; but out in the channels they are to be seen in numbers, accompanied by *Wistaria*, *Rosa Carolina*, and

a host of herbaceous species, rooted on the decaying remains of old tree stumps, or even on the accumulated débris of many generations of *Polygonum*. At the level of the flood water, marking the point where their drifting seeds lodged, but in summer some inches above the water line, are tangles of *Bidens*, *Cyperus*, and other herbs, firmly anchored and vigorously growing in the crevices of the bark of living trees, which still higher are covered with foliaceous Liverworts, Mosses, Colleniate Lichens, and not infrequently, great masses of *Polypodium incanum*.

Where the water is shallower occur the Swamp Maple (*Acer rubrum*, *Drummondii*), *Planera*, the Swamp White Ash (*Fraxinus profunda*), *Catalpa*, and Water Locust (*Gleditsia aquatica*), which, on the gradual intrusion of the low shores or islands, give place to the usual swamp timber, festooned with Supple-Jack (*Berchemia*), Cross-vine (*Bignonia capreolata*), Trumpet Creeper (*Tecoma radicans*), and Grapes. And the beautiful pink clusters of *Mikania*, and the blue foliage of *Cissus stans* stand out in rich contrast with the prevalent green. After a first day of this unwonted experience one emerges into the usual noise and bustle with the feeling that he has visited another world quite different from anything he has ever seen, and scarcely knowing which to admire most—the great solitude of the place or the beautiful way in which Nature's hand has adapted her children to a most unusual home.

Missouri Botanic Garden.

Wm. Trelease.

#### Sun-scald and Means for its Prevention.

SUN-SCALD, as the term is commonly used in the north-west, is the partial or complete destruction of the bark of trees on the part of the trunk or main branches facing the south-west, due, apparently, to exposure to the sun's rays. It is a question whether this damage occurs during the growing season or during winter or early spring. The term is more commonly used with reference to fruit-trees.

My own observation leads me to the opinion that the damage known as sun-scald may occur either during early spring or during summer, under certain conditions, but that the causes of the trouble differ at the two periods. In early spring it probably results from alternate freezing and thawing of the bark, especially when unseasonably warm weather, that excites the cambium cells to activity, is followed by freezing weather. At this season it is most common on young trees on which the bark has not yet become rough and the living bark has not been inclosed by dead cork layers. Often the trouble does not reach to the cambium, and hence does not immediately injure the tree further than to destroy the outer bark layers on the exposed part. In severe cases the bark of older trees may be entirely destroyed on the south-west exposure, so that it loosens from the wood and finally cracks open, exposing the wood to the attacks of injurious insects and fungi.

Sun-scald often occurs during summer on trees that have been recently transplanted or over-pruned, and sometimes during protracted drought on trees of certain species that have not been interfered with. In all these cases the cause is probably the same, namely, the transpiration current, which conveys the water from the soil to the leaves, is so much checked that the bark of the trunk becomes overheated, causing death of the cambium. The Soft Maple, *Acer saccharinum*, when properly treated, is entirely hardy at Madison, Wisconsin, but I have seen trunks of this tree several inches in diameter, the tops having been too severely cut back, with a patch of dead bark some inches wide, and extending from the ground to the lower branches on the part of the trunk facing the south-west. Trees of the Sugar Maple and White Birch, taken from the nursery and planted where their trunks are fully exposed to the sun's rays, are often destroyed by sun-scald the first or second season unless their trunks are shaded. The trouble is not immediately apparent, and is frequently not discovered until too late,

for the foliage of the tree remains fresh. But examination of the bark facing the south-west a short distance above the ground reveals the fact that it is lifeless and that borers have gained entrance beneath it. The latter not only work beneath the injured bark, but eat into the cambium of the live part, thus often completely girdling the tree.

Fortunately, the preventive of sun-scald is very simple, and surrounding the bark with non-conducting material, or shading it in the exposed part, is all that is necessary. Several devices are in use for this purpose. A thin board is sometimes tacked to the trunk so as to face the south-west, or two boards nailed together in the form of an eaves-trough are sometimes tied to the trunk. A single narrow board sharpened like a stake and driven into the ground close to the trunk facing the south-west answers the purpose fairly well. A hay rope wound about the trunk from the ground to the lower branches is often used. A screen, made by weaving common house lath together with wire, has been much used in Wisconsin. This device is rather heavy for slender trees, and if put on so as to reach from the ground to the lower branches it sometimes heaves up in winter, and so does harm. Rye-straw set upright about the trunk and tied on with wool twine makes a protection that costs but one cent for each tree, and is readily applied to a crooked trunk and to the lower branches. Experience shows that this will last five years, which is usually as long as protection is needed. The codling moth and other injurious insects do not appear to harbor beneath this protection, as might be supposed. It has recently been proposed to cheapen this protector by sowing a few kernels of rye or oats about the trunk of the tree immediately after planting, a method that has not yet been tested to my knowledge.

Experiment Station, University of Wisconsin.

##### London Letter.

LILY DISEASE.—Cultivators of *Liliums* have for some years been bothered by a disease which attacked the bulbs when dormant. This was not easily detected, especially in imported bulbs, but soon made its presence evident when the bulbs were planted in moist soil. Its ravages among Japanese Lilies have lately been most alarming, and I believe it has also got into the Lily-fields of Bermuda. Mr. Massee, of Kew, has investigated some diseased bulbs of *L. speciosum* and *L. auratum*, and the results are published in a recently issued number of the *Kew Bulletin*. The disease is first revealed by the discoloration and softening of the base of the bulb-scales, and this increases until finally the whole bulb becomes pulpy and brown. This is caused by a fungus which is described by Mr. Massee as a new species, namely, *Rhizopus necans*, and figures of it accompany his paper in the *Kew Bulletin*. He found that the fungus could not penetrate the unbroken tissues of the bulb-scales, but gained an entrance through wounds and especially through broken roots. He recommends a short immersion in a one per cent. solution of corrosive sublimate or of salicylic acid for diseased bulbs, neither of these substances having any injurious effect on them if not immersed longer than fifteen minutes. In addition to Lily-bulbs it readily attacks and destroys the bulbs of *Narcissi*. Mr. Massee recommends a change of soil for the cultivation of the bulbs, as the fields in which the Lilies are grown in Japan are probably saturated with the fungus. He also recommends the careful lifting of the bulbs and partial drying or "sweating" before they are packed for exportation. It might be well to dip all the bulbs in a solution of salicylic acid before packing them should there be any suspicion of the presence of the fungus. Another disease has lately attacked *L. auratum* in English gardens, destroying the strongest stems in a few days, usually when the flowers are about to open. It has been described as a kind of sun-stroke, and it has all the appearance of scalding.

JOURNAL OF THE ROYAL HORTICULTURAL SOCIETY.—The August number of the *Journal of the Royal Horticultural Society* is of exceptional interest. It contains the list of the "Victoria Medallists" (I omitted the name of the learned Canon Ellacombe from the list which I wrote for GARDEN AND FOREST). A paper by Professor Marshall Ward on Microscopic Fungi and their Cultivation will be read with interest by all cultivators who hope for some cure for the many fatal diseases which now affect garden plants. Diseases of Plants (fungoid), by Mr. Masee, is of similar purport and value to the paper by Professor Marshall Ward. The Value of Artificial Manures is set forth in an excellent paper by Mr. J. J. Willis, probably the first authority in England on this question. A paper on the Storing and Preserving of Fruit, by one of our leading growers, Mr. J. Cheal, gives some useful advice to amateurs as to the best means of preserving and utilizing fruit, especially in times of good crops, when the tendency is to let it waste or sell it for nothing.

ORCHID PANS.—Cultivators of Orchids differ as to the merits of block, teak-basket, pan or pot cultivation, and while some prefer to use baskets for almost everything, others declare that pots or pans are better. The fundamental principle to be borne in mind is that epiphytic Orchids cannot succeed in a compost which is not sweet and open or aerated, and therefore a pot or pan open only at the top and with a small hole in the bottom is not likely to prove safe except in certain cases and in careful hands. On the other hand, teak baskets are apt to allow the compost and roots to dry too quickly. I have recently seen some pans which combine the qualities of pot and basket; these are about half their diameter in depth, with an ordinary rim at the top, the bottom conical and perforated with large holes and the sides also perforated with round and elongated holes. These pans are made of red clay and they have holes for wires to suspend them. They are light and they may be stood on a stage or shelf as safely as if suspended. The advantage such pans have over wooden baskets is that they do not rot and afford a lodging place for fungoid and other pests. They do not require potsherds for drainage, and they do not allow the compost to dry too quickly; at the same time it is impossible for plants to become water-logged in them. I saw them in extensive use in the nursery of Messrs. F. Sander & Co., who have found them so admirably suited for Orchids, Nepenthes, etc., that they manufacture them largely, and now offer them for sale. They are almost as cheap as ordinary pans, the price of one six inches in diameter being twopence. They are therefore much cheaper than baskets; so cheap, in fact, that one need not hesitate to break them if necessary when removing the plants into larger pans.

STRAWBERRIES.—A trial of a select number of kinds of strawberries has been conducted at Chiswick during the last two years. The results are published in the *Journal of the Royal Horticultural Society*. Most of the stocks were planted in August, 1895, but some were planted a year later. It should be borne in mind that probably no fruit varies more than strawberries, both in different seasons and on different soils, and therefore sorts which may prove inferior in one season may be first-class the next. Still, there is not much difficulty in separating the good from the bad in a properly conducted trial extending over two years. The kinds which were voted best of fifty-six sorts tried are as follows. They were awarded first-class certificates. The name of the variety is followed by the raiser's name and the year when it received a certificate. Auguste Boisselot (1890): good crop the first year, much heavier the second, quality excellent; ripe June 11. Countess (1896): splendid crop first and second year, flavor delicious; a very fine variety with a wonderful aroma; ripe June 11. Edouard Lefort (Vilmorin, 1896): splendid cropper, flavor delicious; ripe June 11. Latest of All (Laxton, 1894): very heavy cropper, flavor better the second year; ripe June 15. Royal Sovereign (Laxton, 1892): a grand cropper, quality good;

proved to be the hardiest and earliest variety; ripe June 4. Veitch's Perfection (Veitch, 1896): this variety has won a first place among the newer sorts; it was not received at Chiswick in time to be properly tested but it has proved a superb cropper, large and handsome in berry and of excellent flavor. Wonderful (Bunyard, 1897): good crop first year, very heavy second, quality excellent; ripe June 11. I had an opportunity of tasting and inspecting the varieties here mentioned and in my opinion the best of all, judging by the Chiswick test, was Countess.

PHLOXES (*P. decussata*).—A large collection of the varieties of the popular garden Phlox has been formed at Kew during the last two or three years, numbering over one hundred named sorts. These have been obtained chiefly from the Continental nurserymen, who have paid special attention to the improvement of this Phlox, chief among whom is Monsieur Lemoine, of Nancy, who has bred most of the best sorts in cultivation. A selection of the best of them was made this year, and I give here the list in the hope that it will be helpful to any one wishful to grow a select few of this, one of the most ornamental of garden plants. At Kew, at any rate, the following are preferable to all others tried:—White: Berenice, Sylphide. White with dark eye: Pascal. Rose: Ouragon, John Forbes, Le Siecle, Grevin, Adonis, Moliere, Beranger. Rose-purple: Cœur de Lion, Champs Elysee, Roxelaue. Lilac: Espoir, Eugene Danzanvilliers. Salmon-red or orange: Aurore, Roi des Roses, Regulus, Tom Welsh, Coquelicot, Toreador, General Chanzy. Blood-red: Coccinea. Bronze-violet: Solon. If I had to confine myself to three sorts, they would be Sylphide, Coquelicot and Tom Welsh. Phloxes like a rich soil, an open, sunny position, and plenty of water. In a dry border they lose their bottom leaves and become unsightly. They are easily multiplied from cuttings.

London.

W. Watson.

### The Chestnut in Bloom.

"The bloom is gone, and with the bloom go I."—*Thyrsis*.

THERE never was, nor, perhaps, ever may be a more perfect idea of the transition from early summer into midsummer than is conveyed by two stanzas of "Thyrsis," where the "red and white of May" passes into the deeper coloration of summer, with the "Chestnut-flowers strewn" between. In those perfect lines the English Chestnut is associated with plants of an earlier period of bloom than our native tree, but even closer our native Chestnut touches the high-water mark of the year. After Chestnut-tassels have fallen the time of preparation and expectation has passed, and not only has summer fully come, but autumnal flowers have begun with scouting parties of Asters and Golden-rod.

The past season has been noted for profusion of bloom of every sort, and the "high midsummer pomps" were ushered in by a perfect outburst of bloom from the Chestnuts. Hillside and valley woodlands were in places really illuminated by the cloud of pale golden tassels. One of the most beautiful specimens was a Chestnut found a short distance from Philadelphia, Pennsylvania, near the North Penn Railway (see figure 48 on page 573), and while not remarkably large, it was so perfect in form, so covered with bloom that one could not fail to be impressed by its unusual beauty. It stood far from a house in an open field, and was an ideal tree for the corner of a lawn, with down-drooping branches on one side, and on the other horizontal boughs that framed the landscape beyond. The economic uses of the Chestnut cannot be touched upon at present, but simply its æsthetic side. Every one who travels cannot fail to observe whole districts given up to a petty, trifling kind of planting, and it cannot be insisted upon too often that for broad and lasting effects, for dignity and increasing beauty, we must turn to the Tulip-tree and our Oaks, including with these, of course, the Chestnut. This tree fills such an important part in the landscapes of the Atlantic states, that it is only after passing beyond the Alleghanies one realizes how large

Fig. 48.—A Chestnut-tree near Philadelphia, Pennsylvania.—See page 372.

that part is. It is at home in the forest or beside the roadway; the smallest and plainest farm-house is dignified when sheltered by its overspread boughs, and the most beautiful lawn receives its crowning touch when the autumn sunshine slants through the green and gold of its leaves. The Chestnut disappears soon after one crosses the Alleghanies, and there is nothing the exile on some weary western farm longs for more than the Chestnuts on the hillside at home. An old mountaineer of central Pennsylvania, who has always been to me the embodiment of tree lore, in his recollection of the journey of his parents when returning from the then far west in Ohio, says that near Pittsburg the wind at night had an unusual sound, and on asking his mother what it was, she said, "It's the wind among the Chestnuts: we're nigh home, my boy."

It is this happiness of association that brings them so close to all who know them; no old-time myths of fatal arrows or sacrificial rites are connected with them, they are simply trees always known to us, and dear alike to the careless happiness of childhood, or quiet autumn rambles of later life.

### The Flower Garden in September.

FALLING leaves and chilly nights now indicate the ending of the summer season, and although many warm days may still be looked for, frost may come almost any night. Everything susceptible of injury from slight frost should be placed under cover soon. Generally the first frost in this part of Massachusetts occurs about September 25th, but killing frosts do not come until the second week in October. Cuttings of tender plants, such as *Strobilanthes Dyerianus*, *Coleus*, *Alternanthera*, *Acalypha*, etc., should be got in without delay. We prefer to pot up a few old plants of *Coleus* and box off *Alternantheras* and place them on a shelf in a warm house. Geraniums we do not insert until early in October, when they are placed in well-drained boxes of sharp sand and stood on a light shelf in a cool house. Abutilons are useful as bedding plants; the flowering kinds are suitable for dotting in mixed borders, while those having ornamental leaves are effective in large beds. *Souvenir de Bonn* is one of the best. The new *A. Savitzii* is more heavily variegated, but with us proves a much more delicate grower. Cuttings of these varieties root readily at this season.

Cannas are now probably the most popular, as the most showy, of all flowering plants for ornamental gardening. Some of the older sorts, such as *F. Vaughan*, *Madame Crozy*, *Alphonse Bouvier* and *Queen Charlotte*, are still among the best for bedding purposes, but some of the newer sorts are promising. *Italia*, *Austria* and *Burbank* grow vigorously and are six to seven feet high and of proportionate spread. The flowers, however, lack the substance necessary to stand our hot midsummer suns and bleach out badly. At present, with cooler weather, they are superb, and more attractive than any other sorts. Probably under glass they would do well. *Captain Drujon* is a good yellow in the way of *Florence Vaughan*, the spots on the petals being lighter in color. *Souvenir d'Antoine Crozy* is good. *Papa Canna*, while not a specially attractive color, is a free bloomer. *Beauté Poitevine* is one of the best reds we have grown. *Eldorado* still holds its own as a yellow. *Madame de Montefiore* is also good. *Charles Henderson*, *F. R. Pierson*, *Columbia*, *General de Miribel* and *Gloire de Montet* are all superior, and should be in every collection. Cannas are excellent winter-blooming plants, and we pot up at least one of each variety. These are kept quite dry for about two months after watering, and when the Chrysanthemum season is past they are placed on a side bench in a house with a minimum temperature of fifty degrees.

The past summer has been specially favorable for tuberous Begonias, which have done better than ever before, the moist season suiting them. A border shaded from the afternoon sun, filled with fibrous-rooted Begonias in variety and Fuchsias and bordered with *Rex Begonias*, made one of the most pleasing displays we have had this season. More of these Begonias should be used; among flowering varieties, *Haageana*, several of the *Semperflorens* type, *Nitida alba* and *rosea*, *Bismarck*, etc., and among foliage sorts *Thurstoni*, *Metallica*, *Alba picta* and *Manicata variegata*. We plant out all the stock we have used for winter blooming and propagate young stock for

another season's supply in pots. Fuchsias do not succeed in beds exposed to full sunlight all day, but when partially shaded and grown as short standards they are pleasing. In Great Britain enormous numbers of Fuchsias are used for bedding purposes, particularly in the London and other parks. Beds of Standards are charming there in a groundwork of some dwarf close-growing plant.

Perennial borders are now beginning to look somewhat dishevelled, but a variety of *Helianthus* and *Asters*, with a number of *Phloxes* and an assortment of annuals keep them from looking cheerless. *Anemone Japonica* and its white forms, *Honorine Joubert* and *Whirlwind*, are now in season; these are only hardy here if well protected by leaves. We grow a few in pots for use in the conservatory, where they fill in a blank until *Cosmos* and early *Chrysanthemums* come into flower. Seedlings of various perennials sown during July are now in some cases of good size in nursery rows; more slowly germinating ones of smaller size will be pricked out in a cold frame and kept there over winter. Biennials such as *Sweet Williams*, *Canterbury Bells*, etc., need the ground stirred about them to keep growing well. The more tender sorts are planted in cold frames during October, while the hardier ones are set out in their places in the perennial borders. Dutch bulbs are now arriving, and as soon as frost cuts down plants now in the flower-beds these will be planted out, as they lose their vitality in paper bags.

Late *Asters*, which may not open out before they are caught by an early frost, if lifted with a good ball and planted in a cold frame will give some useful flowers for cutting. Summer-blooming *Carnations* are now at their best. It is a good plan to treat some of these in the same way as the *Asters*. The flowers will come cleaner and last better under glass, and the heavy night dews spot the flowers badly, particularly the white and crimson ones. *Violets* have appreciated the moist summer and look exceptionally well. The plants have recently been transferred to their winter quarters, as the heavy September dews, followed by hot days, seem to be specially favorable for the spread of the dreaded "spot."

Taunton, Mass.

W. N. Craig.

### Some Showy Annuals and Perennials.

A LARGE bed of *Cleome spinosa* is much admired for its large, upright racemes of showy rose-colored flowers. This exceptionally good annual plant can be recommended for large beds in open sunny positions, where the flower-clusters will keep on elongating and blossoming for two or three months. Our plants are raised from seeds sown in pots in the greenhouse early in April. When the seedlings are large enough they are potted off singly into small pots. About the end of May the plants are set out in beds in the garden, where they begin to blossom in the early part of July and continue in flower until frost destroys the plants. This showy plant is a native of the West Indies and tropical America. It has escaped from cultivation in some of the western states, and is also found on waste grounds southward. It is slightly more than three feet high and has prickly stems. The leaves, which are covered with clammy hairs, are of good size and are digitate, made up of five or seven leaflets. Seeds are produced plentifully, and young plants are easily obtained from them. There is a white-flowered form of this plant which is also desirable.

A near relative to *Cleome spinosa* is the native annual, *Polanisia trachysperma*. The plant grows about two feet in height, and is terminated with clusters of white flowers produced in leafy racemes. It has a long blossoming season and produces its flowers most plentifully during the hottest part of summer. It requires the same cultural treatment as *Cleome*.

*Verbena venosa* is a perennial plant of free-flowering habit, but as it is not quite hardy here it is grown annually from seed. It is more vigorous and not so liable to be destroyed by mildew as the hybrid kinds. Massed in an open, sunny position it is showy when in flower, with bright lilac or bluish blossoms. The branching plants are from one foot to eighteen inches high. Seeds are produced freely. This native of Brazil was introduced from there in 1830. *V. Aubletia* is a native plant not quite hardy here, but we find it well worth the trouble of raising from seed annually. Its showy, abundant reddish purple flowers make a good display during late summer and early fall.

The desirable native annual, *Centaurea Americana*, is seldom seen in gardens in this vicinity, although some of our seedsmen offer it in their lists. It is easily grown from seeds, and if sown in April the plants will blossom in July and August. The erect-growing plants have stout, well-clothed stems which

are terminated by large, showy rose-colored flower-heads measuring four inches in diameter. It is at home on the plains of Arkansas and Louisiana to Arizona.

Harvard Botanic Garden, Cambridge, Mass.

Robert Cameron.

### The Cultivation of Dutch Bulbs.

THE time for planting Dutch bulbs has now arrived. The first planting of Roman Hyacinths is already made; they are forced in large quantities by florists, and although rather common during the holiday season, these charming flowers are always favorites.

While Hyacinth culture is easy, there are some constitutional requirements which must be heeded. The Hyacinth is essentially a hardy plant, and cannot be forced quickly into bloom. Between the time of planting and the appearance of leaves there must be a root-forming period. The conditions of pot-culture differ from those in the open ground. In pots the bulb can barely be covered unless very large pots are used, and the consequence is, as many amateurs have found, that the roots in striking earthward become confined and force the bulbs out of the pots. Added pressure will keep them down, and after the pots have had a good watering the surface may be covered with two or three inches of sand or coal-ashes. Our plantings will be kept under the bench of a cold house, mostly for convenience. Cold frames answer as well, but must be well protected by mats and shutters during winter and have a banking of leaves or litter on the outside. We protect the cold frames well so that pots may be taken out at any time during the winter. If the Hyacinths are not wanted until spring a little freezing is beneficial rather than otherwise, providing the sun does not strike them. Roman Hyacinths naturally bloom earlier and force more readily than the show varieties, and therefore do not require so long a rooting period. The show varieties should not be unearthed until the flower-stem shows well among the leaves. In the meantime the plants will probably require one good watering, especially if the ground on which they are set is dry. A good indication in this respect is the drying out of the covering. My bulbs are so placed that I do not find it necessary to water them after potting time. Show varieties come on slowly and they are always better for a good start. Even though apparently drawn they quickly assume their natural green color on exposure to light. It is beneficial to stand the pots in a cool house for a few days before the plants are forced. A shorter and better proportioned flower-spike is obtained when the plants are forced slowly. Really no forcing is required if there is time to wait for the flowers, and they will come along well in a night temperature of forty-five degrees, Fahrenheit. These cultural remarks apply, with scarcely any variation, to all forced Dutch bulbs.

Wellesley, Mass.

T. D. Hatfield.

**Russelia juncea.**—Though not one of the showiest of our greenhouse plants, this is certainly worthy of a place in every collection. It is specially serviceable where hanging plants are required, and owing to its pendulous habit it can only be shown to advantage in this way. The flowers, which are trumpet-shaped about one inch long and of a brilliant scarlet color, are freely produced nearly all the year through. The numerous long, rush-like, branching stems are clothed with small linear or lanceolate leaves. It is a plant of comparatively easy culture; it can be grown either in pots or baskets, and delights in a light, moderately enriched soil. A house where a night temperature of fifty-five to sixty degrees is maintained during the winter months will suit this plant well. The most convenient method of propagation is by cuttings made from the little branchlets taken off with a heel. These root readily in sand or sandy soil in a propagating-case with gentle bottom-heat.

Tarrytown, N. Y.

William Scott.

**Garden Plants in Autumn.**—An effective subtropical bed in the flower garden on the estate of H. H. Hunnewell, Esq., is made up with several large plants of *Eucalyptus globulus* for the centre, and these grow twelve feet high. *Grevillea robusta*, Rubber-plants, Cannas with colored foliage, *Acalyphas*, *Alocasias* and *Abutilons* are massed about these, with a circle of *Coleus Verschaffelti* and *Cineraria maritima* for an edging. *Desmodium penduliflorum* makes a good autumn-flowering plant for the herbaceous or shrubbery border. By the graceful way its willowy branches fall away on all sides to the ground I should think it a first-rate plant to use for separate specimens on grassy slopes. Its distinctly Pea-like purplish flowers are borne on short racemes toward the ends of the branches, in the same way as in

our garden *Cytisus*. *Amaranthus caudatus* is a good hardy annual, but, like many other excellent border plants, it would soon become a weed if allowed to spread. Persons seeing this plant for the first time are always impressed with its beauty. It is very effective in the subtropical border, where its purple plumes sometimes grow to the height of six feet.

### Correspondence.

#### Notes from the Ozark Fruit Regions.

Sir,—These notes were mostly made at the Olden Fruit Farm, in Howell County, Missouri, on the southern slope of a spur of the Ozark range and about twenty-five miles from the Arkansas line. But the methods advocated and largely practiced there, while advanced in some respects, are practically the same that obtained throughout the Ozark fruit region.

On so large a fruit farm, comprising 3,000 acres, every department of the work is on a correspondingly large scale. Thus, in the propagation of young stock, peach stones that have not been allowed to heat or sour are sown broadcast in October on the surface of ground that has been fertilized (after having been previously used for the same purpose) by the cultivation of Cow Peas—the so-called salvation of the Ozarks—for one year. The proportion of seed used is from three to four hundred bushels on a space sixty feet square—the seed being literally shoveled onto the ground—and then plowed under to a depth of from two to four inches. These sprout the following spring, coming up as thickly as grass. While the seedlings are very small they are transplanted into nursery rows three and one-half feet apart and about three inches apart in the rows. The following August they are budded, as close to the surface of the ground as it is possible to work, with any variety the grower chooses, and the Elberta is the usual choice, although thoughtful growers begin to doubt the wisdom of the universal cultivation of one variety, no matter how fine, the simultaneous marketing of the great Elberta crop of this year having seriously demoralized prices. The following spring the seedling tops are cut off and the bud nurtured through the season. The next spring, the root then being two years and the bud one year old, the trees are ready to set in orchards, and are considered better for the purpose than when older; indeed, any left after the next spring are rooted out and destroyed.

Peaches are always planted on the highest ground as a protection from late spring frosts, and the best results follow the use of ground that has been cleared of timber and brought under subjection by the cultivation of one or two crops of beans, potatoes, or even corn, though a low crop is considered preferable to corn. But if quick results are wished the stock is set at the rate of one hundred and sixty trees to the acre on new ground that has been cleared of native growth, the wood is burned, the clearing is grub-plowed, the worst of the stumps are picked off and also burned and the soil is harrowed. Corn is then grown in the orchard until the trees are three, and in some instances, four years old, after which, for the best results, the ground is cultivated each year until midsummer; but some growers omit this cultivation to the detriment of the crops. Peach orchards on such virgin soil need no fertilizing for at least ten years, but when new orchards are established on old, worn-out land Cow Peas are used to regenerate the soil, being sown in drills and cultivated. If the ground at any time shows great deterioration the crop is turned under, but usually simply growing and cultivating a crop of Cow Peas is accounted sufficient, and in most cases hogs are turned in to harvest the crop.

Peaches bear at three years and are profitable at from four to six years of age, and the oldest trees at Olden, now fourteen years old, still bear heavily. In a good peach year four-year-old trees will average two bushels each, but ordinarily one bushel is a fair average. The crop is less certain than that of Apples. There have now been three heavy crops in succession in Howell County, and in fourteen years there has been one instance of two successive years of crop failure.

No known case of either Yellows or Rosette has occurred in the Ozark region, and insects are less troublesome than in older orchard countries. Peaches were sprayed this year at Olden for the first time and with satisfactory results. The first spraying was done immediately after the fall of the bloom and was repeated three times at intervals of ten days. A preparation of arsenate of lead made and applied under the direction of Professor Stedman, of the Missouri Experiment Station, was used on every alternate five rows throughout a forty-acre orchard, which thoroughly disposed of the tent-

caterpillar and gouger and greatly lessened the ravages of the curculio, while it in no wise injured the foliage. The preparation is to have further trial before the formula is made public.

Brighton, Ill.

Fanny Copley Seavey.

### Fruit-trees in Arkansas.

To the Editor of GARDEN AND FOREST:

Sir,—As the summer season in north-western Arkansas is somewhat longer than in Massachusetts, a greater growth of the Burbank Plum is made here than that reported by your correspondent from Massachusetts on page 347.

In April, 1895, I set out a small-sized Burbank Plum, and it now measures ten feet in height. Last spring the branches were cut back to eight inches, and it has grown a little over four feet this season. All fruit-trees grow rapidly here. A small yearling Peach-tree transplanted in the spring of 1895, when the top was cut off at the root, is now fourteen feet high and ten inches in diameter. This year it was heavily loaded with fruit. An Elberta Peach-tree budded a year ago is eight feet high and is still growing. A Gibb Apricot has grown six feet this season. The entire top of an Early York Nectarine was broken off last winter; a sprout started near the ground, and now measures five inches in circumference and is five feet high. Several dwarf Pear-trees have grown five feet this year, and a Kieffer six feet.

Trees bear when very young, and it is no uncommon thing for a tree five years old to bear a bushel of apples, and for Peach-trees to bear moderately when two years old.

Decatur, Ark.

A. R. Plank.

### The Marsh at Rose Brake.

To the Editor of GARDEN AND FOREST:

Sir,—September, in this part of the country, is usually a dry month. The roads are hot and dusty, the garden has a discouraged air, the leaves are limp and withered, and the flowers hang drooping from their stalks. The only fresh and verdant spots are the banks of streams and the moist places of the farm where the springs well-up from the limestone rocks underground.

One of the attractions of Rose Brake is its acres of unrequited marshy ground, which we have made a present to Nature, and over which she holds undisputed sway. Here beauty revels in these September days in a riot of color and bold and picturesque effects. Through beds of Mint and Moss and many gay blossoms now in their prime, winds a stream which is fed by many springs. This is the wild-flower garden that far outrivals our poor attempts at cultivated borders on dry and rocky hillsides, which are only successful in spring and early summer. It is to the marsh that we go with shears and baskets now to garner some of this lavish harvest of bloom for the decoration of home and little church.

Various are the surprises here. In one place the stream runs between beds of a low-growing showy yellow flower, the common *Bidens chrysanthemoides*, first cousin of the hateful Spanish Needles, but which makes here a beautiful picture of dewy freshness by its lavish display of bright golden blossoms set in greenest grass. Then there are large patches of the crushed-raspberry-colored Joe-Pye Weed, with fringes of a white species of Eupatorium to give variety. In another place a rank growth of Golden-rod and Yellow Cone-flowers is mingled with the reddish purple of Iron Weed and Marsh Thistles six feet in height, of the same reddish hue. Here are flowers, not in small, primly-ordered borders, but in masses of bright colors acres in extent, harmoniously arranged and blended by the master-hand of Nature. Here are no conflicting hues, no stiff monstrosities, no double Sunflowers and Dahlias, and China Asters and screaming Zinnias whose colors set one's teeth on edge, all in a meaningless jumble, without form and void of beauty, such as one sees in the gardens hereabouts. The effect of our bright marsh garden is toned down by its quiet setting in wild shrubbery, which includes seven species of Willow, and Wild Roses, Viburnums, Thorns, Sycamores and many other plants. Here, too, the Bittersweet and Honeysuckle escaped from cultivation, and the native wild Grapes festoon at will the growth on the banks of the stream, and huge rocks elbowing each other form gloomy recesses where Ferns and Mosses love to hide and birds to build their nests. Tall, rank Sedges and Grasses gone to seed mingle effectively with the brighter coloring of the flowers.

In one place I noticed a patch several yards in circumference of *Cuphea viscosissima*, an insignificant little plant as usually seen in dry soils, but here in the rich muck and bloom-

ing lavishly, it makes an effective patch of a rather pleasing light magenta color, contrasting not unfavorably with some neighboring clumps of *Coreopsis* and *Chrysopsis Mariana*. In some places the Jewel-weed is unusually rank and tall and free-flowering, and large clumps of it, studded with bright orange-colored blossoms, are framed in a setting of blue *Ageratum*.

In a damp corner of a pasture-field we find a thriving colony of the lovely blue *Lobelia syphilitica*. No other flowers are near by to mar the effect of the bright blossoms growing out of the fresh Mint and Grass, and it is a delight to sit upon a mossy stone and revel in the blue and green surrounding one in perfect accord with the clear blue of the sky and the tender green of the Honey Locust trees that overhang the spot. From this point of vantage we survey the extent of the marsh and take in all its beauty and are glad.

### Native Plants for Ornamental Planting.

To the Editor of GARDEN AND FOREST:

Sir,—Your recent editorials recommending the use of native local plants for the ornamentation of small country places ought to open many eyes to the variety of the examples offered by Nature's products, not merely in the meadow and by the brookside, but even along the high road, where conditions of growth are usually less favorable. For example, I noticed recently by a country roadside in this part of southern New York, an "arrangement" of Nature's making which might well be imitated by a planter of taste, and which could not easily be rivaled by any created with exotic garden shrubs and creepers.

Between a sloping hillside and the road, sweeping downward to a border of Grass just as one might desire it to do in ornamental grounds, ran a long narrow clump of Sumachs. Their handsome dark red panicles were at their best. The deep green of their foliage was varied by the beautifully lobed leaves of our most beautiful wild Vine, *Vitis æstivalis*, while its stems were hidden from view. And over all, not as a thick covering, but in sparse, graceful tendrils, ran lengths of the Virgin's Bower, bearing charming clusters of starry white flowers. This was only one of the striking instances of beautiful "arrangements" casually produced with native plants which I noticed in the course of a single afternoon's drive; but it is enough to show that no one need depend for variety of effect, any more than for beauty, upon the resources of the gardener. Perhaps in two or three years this particular bit of Nature's planting will have lost its beauty. Very likely the Vine and the Clematis will have strangled the Sumachs—I mean, will have overrun them with heavy masses of their own foliage so that the artistic-seeming arrangement of to-day will become a somewhat formless tangle in which the individual charm of the component parts will be lost. But this is just where man has the advantage of Nature. In the pleasure-ground discreet pruning or uprooting might keep such an arrangement perfect for many years, while Nature, bent upon growing as many plants as she can as fast as she can, cannot pause to preserve special effects of peculiar beauty.

Tuxedo Park, N. Y.

M. G. Van Rensselaer.

### The Jewel-weed for Cutting.

To the Editor of GARDEN AND FOREST:

Sir,—In your issue of GARDEN AND FOREST for August 18th, in the article on the August wild flowers, it is said that the lovely Jewel-weeds, *Impatiens pallida* and *I. fulva*, are useless for house decoration, and this is almost true. However, after repeatedly hurrying it into the house and into water, and failing to save them, I carried the water to the flower. By gathering the graceful sprays early in the day or very late, or on a cloudy day, and by cutting the stems off immediately a second time under the water, I have succeeded in having fresh Jewel-weed in the house.

### Recent Publications.

*Familiar Features of the Roadside: The Flowers, Shrubs, Birds and Insects.* By F. Schuyler Mathews. With one hundred and sixty drawings by the author, and many of the songs of our common birds and insects. New York, D. Appleton and Co. 1897.

Books about Nature in her more familiar moods, as distinct from books of travel and descriptions of scenery, have

in recent years become more and more numerous. And the wide welcome accorded them proves a growing interest in our public as regards a knowledge of Nature's products, animate and inanimate. The two classes into which such books naturally fall—the æsthetic and the scientific—seem to be equally popular, while the more exceptional works which unite real information of a scientific kind with a really adequate and personal interpretation of Nature's beauty and charm, are deservedly the most warmly welcomed of all.

Of course this evident demand for books which enlarge the perceptions, broaden the knowledge, and deepen the feelings of the average reader who is neither a trained artist nor a professed student of science, has brought forth many works which fall below the level of real utility. And, unfortunately, the book now under review must be ranked among these. It contains many scientific facts of more or less value and interest, and many expressions of pleasure in natural beauty. But the facts are so ill-arranged and for the most part so inadequately explained, that the reader will hardly close the book feeling that his knowledge is much enlarged. And the endeavor to interpret beauty seems to have been almost wholly futile and, in certain ways, actually misleading.

One great fault in this book is that it lacks consistency of plan. If it showed the familiar features, animate and inanimate, of our roadsides, in any systematic way whatever it would have a genuine claim to praise. But it does not confine itself to any special locality nor, on the other hand, does it draw comparisons between different localities. Various parts of our eastern states are referred to on various pages, but no clear picture of any is presented, and most of the geographical references will leave the reader in doubt whether or no the plant in question is narrowly confined to the indicated district, environment, or spot. Again, while some attempt is made to follow the procession of the seasons, it is not systematically carried out. After a chapter on Early Wild Flowers and one on Early Flowering Shrubs we are not told about those of the following weeks—we are jumped into two chapters on Shrubs Belonging to the Rose Family; and the subsequent ones are as heterogeneously arranged. Moreover, heterogeneous material is intruded into some of the chapters in a way which must perplex any reader devoid of botanical knowledge. For example, in one of the chapters on the Rose Family a paragraph about plants which furnish food for birds is inserted, and no indication is given that they do not belong to the Rose Family except by the mention of their scientific names, and this will not make the fact plain to an unlearned reader.

It should be understood that this is distinctly a book for beginners, not for those who have made even the first steps in botanical knowledge. Therefore such faults and failings as we have pointed out seem to us radical. The only way to show a beginner that nature is interesting, and that the study of its products means something more than a memorizing of Latin names, is to group facts in some sort of logical sequence. We do not say that Mr. Mathews has not attempted this in the volume before us, but he has certainly not attained it. Nor are his facts always as clearly and accurately put as they should be in an elementary work. To say that *Cornus florida* "bears a large flower with four notched, petal-like, showy white leaflets set around the tiny greenish florets," cannot convey any definite idea to an uninstructed reader. It seems extraordinary that if it was felt needful to indicate that this "flower" is unlike ordinary flowers, it did not seem essential to explain its structure correctly, especially as such an explanation might have been made perfectly clear and extremely interesting to the least patient eye. Again, if it was worth while to mention that the Indian Pipe is "odd" it was surely worth while to explain its oddity better than by saying it has a "frail, fleshy, single flower." And defects of a more fundamental kind are indicated by the fact that while Mr. Mathews devotes a

chapter to Shrubs and Flowers Belonging to the Heath Family he gives no slightest indication of why these plants are grouped together in one family. Not interest but discouragement, not a belief in the reasonableness but a strong suspicion of the unmotivated wilfulness of scientific classifications, must be awakened in the novice who is conducted from the *Rhododendron* and Mountain Laurel to the *Pipsissewa* and the Indian Pipe without any hint in regard to the basis of the classification which brackets them together.

Mr. Mathews's treatment of birds and insects may be left for appraisement in other pages than these. But here a word must be said about his point of view as regards natural beauty. His remarks upon this subject are most often in praise of a phase of art which he calls "impressionism" and of the high intelligence of the "impressionist." These terms are not explained. It is not even implied that impressionism is a modern phase of art which, like all others, may be attempted by foolish or feeble as well as by capable artists. We are told, as the concluding lesson of the book that "The impressionist has in his possession the key to Nature's mysteries of color," and on another page that "the commonest weed by the roadside becomes one of the most beautiful things in the world when the strength of its color is portrayed on the impressionist's canvas." Surely, there were kings before Agamemnon; and as surely every one with a paint-box who calls himself Agamemnon does not deserve the name. Of course Mr. Mathews knows this, but in a book for beginners it is well to make such things plain; and it is also well to give some interpretation of terms not generally understood, and not very concordantly defined even by those who think they understand them. It is altogether a matter of speculation what the author understands by the word æsthetic as used in a sentence, describing the Joe-Pye Weed, which runs: "This is rather an aspiring weed, which furnishes the lowland landscape in summer with the most consummately æsthetic pink tone which it is possible to imagine. (The Joe-Pye Weed, we may note, is more aspiring than the limiting word "rather" would lead one to suspect, and it grows in other localities as well as in the lowlands.) Again, we are told that "the splendid color of the October landscape is æsthetic" while "that of snakes, butterflies, beetles, birds, and flowers is beautiful only as far as it is brilliant, or pure, or variegated." Such statements as this must confuse the beginner in the art of appreciating beauty quite as much as Mr. Mathews's lack of clearness in scientific definition must confuse him with regard to the science of classification. Nor can much that is inspiring be gathered from the descriptions of an author who permits himself to speak of the "even yellow" of the Sugar Maple in autumn and the "sober scarlet" of the Red Maple; who mentions several times the "neutral gray-buff of the road," not noting that roads differ almost as much in color as green leaves; who has such curious ideas in regard to what may be called the terminology of sizes that he describes the "tiny" blossoms of the Yellow Hop Clover as "scarcely larger than one's thumb nail"; who says that the color of the *Rhodora* is "too near the unpopular magenta to make it a favorite with anybody but an enthusiastic poet," and on another page declares that the immature fruit-clusters of the Dwarf Blueberry "are of the most beautiful æsthetic hues: green, magenta, pink, purple and violet." The mention of the *Rhodora*, by the way, offers an opportunity to illustrate what we meant by saying that Mr. Mathews's geographical indications may easily mislead. He remarks that the *Rhodora* "is readily found in the vicinity of Concord and Lexington, Massachusetts," and that "it is also seen in cultivation in the Arnold Arboretum near Boston, and the Harvard Botanic Garden, Cambridge." A beginner might well be discouraged by these words from looking for the *Rhodora* anywhere else; and indications of this seemingly exclusive kind are very frequent in Mr. Mathews's book.

Some of his little drawings of plants are good; others,

like the picture of an *Hepatica*, do not give a true idea of the plant. His drawings of birds lack character and delicacy; and the many landscape views are far below the average to which the eye of the public has grown accustomed in the pages of our illustrated magazines.

### Notes.

Miss Maria Audubon is translating from the French for publication the hitherto unpublished journals of her distinguished grandfather.

Among seasonable vegetables are cranberry-beans, the large rose-colored pods enclosing fleshy white beans splashed with pink. These sell for forty cents a half-peck. Tomatoes of perfect form and color and of high quality with respect to texture and flavor, are coming from the vicinity of Chicago. These are the choicest offering of this vegetable in the New York markets now, and bring fifteen cents a quart.

Limes from the West Indies are among select fruits now in season, and occasionally a bunch of red bananas is seen; the latter cost sixty cents a dozen, a price considerably in advance of that asked for the best yellow bananas. Owing to the effect of the war in Cuba on trade with that island none of this red fruit has been seen in our markets during the past year, and a cargo of many thousand bunches of yellow bananas from ports in Central America may include only one or two bunches of the red fruit. Among other imported fruits are Alligator pears, from Venezuela; these sell for twenty-five cents each. The large, smooth, oval fruits known as Spanish melons in the trade and which come from Italy, find a limited demand at fifty cents apiece.

In an account of the present condition of the artificial silk industry in the *Revue Industrielle* it is stated that patents have quite recently been taken out by Dr. Lehner, of Switzerland, for the manufacture of an artificial silk made with wood-cellulose, or, more simply, with sawdust. This product is, however, highly inflammable and more costly than real silk, so that there is opportunity for improvement in the new industry in the way of economy and safety. Among other substitutes for genuine silk is mentioned a cotton fibre treated so as to have the lustre of silk by a process patented by Monsieur Oswald Seyfert. This Seyfert cotton is said to be on the market in competition with other artificial silks, and at a fairly reasonable price.

Hardy Bamboos are beautiful in the Royal Gardens at Kew at this time, and every year seems to reveal new attractions in habit, sheath, curve of culm, etc. In writing of these Bamboos, Mr. Watson says they do not flower, or if they do so much the worse for them, but they have variety enough to be of perennial interest without flowers. They have to be watched to prevent their outrunning the space allotted to them, but in almost every one of the numerous species grown at Kew there is a vigor and persistency of growth shown which suggests much usefulness in the large garden and park, particularly in the neighborhood of water. They are not known yet, and those who know least about them are apt to decry their merits. But they are essentially plants for general use. Two new species have lately been added by Mr. Freeman-Mitford, namely, *Arundinaria metallica*, which is intermediate between *A. Veitchii* and *A. humilis*, and *Phyllostachys fulva*, a near ally of *P. nigra*. These are both from Japan.

In a recent article in which reference is made to the influence of forests on farming, the *Boston Transcript* says that soil, moisture and heat are the three servants of the farmer. The soil he can regulate by culture and fertilizers, but moisture and heat seem out of his control. These are not out of the control of the woods, however, and the farmer by judicious management of his tree-plot can bend them to his ends. He can prevent or temper the effects of atmospheric changes, he can avoid the disasters of excessive rainfall, and he can manage the water to his own benefit. It is explained that the snows of winter are conserved by the shade of the trees and do not rush away at the earliest moment of sunshine to swell the spring freshets; the loose soil of the woods, not hardened by the impact of the raindrops, holds the water and lets it percolate to the springs below; the tree-covered area catches more of the snow, and the shaded surface does not give up its moisture in evaporation; there is more water there and means are present to prevent its waste so that the subsoil distribution is better and stronger, and it is the subsoil waters that are the farmer's standby in case of need.

The first Japanese persimmons of this season, from Florida, are now seen in choice collections of fruit, and cost fifty cents a dozen. Grape-fruits are another novelty just received from the same state, and sell for \$2.00 a dozen. Bartlett pears of the largest size are showy yet, although their rich yellow color lacks the bright marking of the smaller fruits seen earlier in the season. These sell for from sixty to seventy-five cents a dozen in the fancy-fruit stores, together with selected specimens of Duchesse d'Angouleme. Seckel pears, from the Hudson River district, are in demand for their rich, spicy flavor, and the best cost twenty cents a dozen. Even the most ordinary fruits are arranged with taste and displayed to the best advantage, and three-pound baskets of Concord grapes are made up of short sections of the vine with two or three bunches of the fruit attached. Crawford peaches of immense size are seen in the best markets, which have been cut from the tree with a bit of the branch and a leaf or two, and a basket holding twenty-four of these handsome fruits sells for \$1.25. The first Cornichon grapes, from California, sell for fifty cents in five-pound packages. It is surprising to see huckleberries shown so late in autumn, and after cranberries are regularly in season.

Stockbridge, Massachusetts, claims to have been the pioneer in the organization of the Village Improvement Societies now existing in many states, and the work of the Stockbridge Society, which is called the Laurel Hill Association, has steadily broadened out. It now has district committees to care for the different sections of the town, and also special committees charged with the supervision and improvement of parks, squares, street sprinkling, street lights, the removal of snow, the care of cemeteries and other special matters. One of its members has recently suggested a combination between all similar societies in Berkshire County, or, if possible, in a still wider area, to work for rural improvements and for the preservation for public enjoyment of places of great natural beauty or historic interest. Of course, efforts toward the latter end have already been made in many localities, but the combination of small local bodies would further this good movement and awaken popular interest in it. Such coöperation would tend to effect, along deserted farm fronts in the country, tree-planting, weed-cutting and the making and preserving of openings through brush or trees for a passing sight of beautiful scenery. As has been said by one of the members, it would mean good roads everywhere, tidiness in the villages, the doing away with flaming circus posters and patent medicine advertisements. After a time no farmer would build his unsightly barns across the road from his house, or put his cattle-shed between his windows and a beautiful landscape. Ugliness and neglect would be looked after between the towns, a common recreation-ground would be established and a reservation of the most wild and beautiful spots would be effected.

Concerning local adaptability of varieties to certain soils and climatic conditions, T. V. Munson, in a recent number of *The Rural New-Yorker*, states that adaptability or non-adaptability applies more to the species than to cultivated varieties. As an example Mr. Munson cites the fact that not one or a few varieties of the Muscadine species of Grapes, but all the vines of this species, succeed well in good soils in the south, but never in the north. All Mustang Grapes do well in almost all soils and situations in the dry south-west, but fail entirely in the cold, damp north-east; no other species is so generally successful in Texas. But on all upland, sandy soils, known as Post-Oak lands, the Post-Oak Grape, *Vitis Lincoecumii*, succeeds perfectly if in well-drained soil, but fails in seepy and bottom lands. Vinifera varieties almost always suffer in all the southern states east of the one-hundredth meridian from mildew and rot in foliage and fruit, as well as with phylloxera at the roots, showing clearly that the species is a native of very arid regions, where these diseases do not exist, and agreeing with the accredited habitat of the species as being in the arid regions of Persia and other central southern Asiatic regions. The native Grapes of Arizona invariably suffer severely from mildew and rot when moved into the Mississippi valley. In black, waxy, very limy lands in Texas the *Labrusca* class of Grapes almost always fail, and do poorly anywhere in the interior south-west; their inability to endure appears to be in their having masses of fine surface roots, and no ability to push deeply into the soil, as do the southern species. In New York varieties of no other species succeed better than those of *Labrusca*. Examples of local adaptability are given also of other fruits and of vegetables and trees, and it has been Mr. Munson's experience that if species which do best in a peculiar soil and climate are taken to a different locality and new varieties are grown there, these new varieties will do better in the climate and soil where their parents came from.

The Forests of Alaska.

THE great maritime forest of north-western North America, which at the south embraces the Redwoods of California and spreads over western Oregon and Washington, terminates on the Alaskan coast on the eastern shores of Kadiak Island, just below the fifty-eighth degree of north latitude. Taken as a whole, this coniferous forest is unequalled in productiveness and in the size, beauty and value of its trees. Not only is the Redwood the largest of all conifers, with the single exception of its relative of the Sierras, which excels it in bulk of stem and branches, but not in height, but in this maritime forest are found the largest Spruce-tree and the largest Hemlock in the whole world. Of the Arbor-vitæ here grows the giant of its race; and of all the Cypress tribe none can equal Lawson's Cypress in majesty of port. Here, too, the Alder becomes a great tree, and Firs assume their noblest proportions. To-day, however, we would speak more particularly of that part of this forest covering the coast mountains of south-eastern Alaska, and which in many of its general features resembles the forests of Puget Sound and of western British Columbia, although the Douglas Spruce, the most abundant tree on the shores of Puget Sound and Vancouver Island where it surpasses all its associates in height and in size of stem, does not reach Alaska. The White Fir (*Abies grandis*), which is so conspicuous with its tall pyramids of lustrous dark green foliage on the shores of the Gulf of Georgia, is absent, too, from the Alaska forest, as is the Great-leaved Maple (*Acer macrophyllum*), abundant in all the coast region further south. The Arbor-vitæ (*Thuja gigantea*), which is common and of fine size on Prince of Wales Island and on the southern part of the Cleveland Peninsula, is rare, if it exists at all north of latitude fifty-six; and the coast forest of south-eastern Alaska is composed almost entirely of two trees, the Sitka Spruce (*Picea Sitchensis*) and Merten's Hemlock (*Tsuga Mertensiana*). From the edge of tidewater these two trees grow up to the timber line, which varies in elevation from 2,500 to 4,000 feet, everywhere in dense, serried masses, like the blades of grass in a meadow, covering all islands and the seaward slopes of the mainland mountains, which shut off the moisture from the dry interior. Sometimes the Spruces pre-

dominate, especially toward the north; sometimes the Hemlocks are more abundant, and often the two are mixed in nearly equal numbers. Through this forest the Sitka Cypress (*Cupressus Nootkatensis*) is scattered, usually at elevations of about 1,000 feet above the sea-level, although it often descends to the water's edge. It grows not in large bodies, but often in numbers sufficient to enliven the sombre Spruces and Hemlocks with the cheerful yellow tints of the graceful frond-like branchlets which descend from the wide-spreading branches of this splendid tree, unrivaled by any other American conifer in the beauty and value of its wood. On the margins of the little flats and beaches which occur only at the mouths of streams—for on the Alaska coast the mountains usually rise abruptly from the sea—Alders of two kinds and the lovely Sitka Willow light the borders of the forest; and Alders sometimes extend up the banks of streams or hang over rocky sea-cliffs. On sloping seashore bogs, rich in mosses and studded with many charming herbs and dwarf shrubs, *Pinus contorta*, the only Alaskan Pine, occurs rather sparingly; and on Baranof Island, near the town of Sitka, Patton's Spruce (*Tsuga Pattoni*), which is probably widely distributed over the coast mountains at high altitudes, descends with a few small individuals nearly to the sea-level. These, with the addition of the Balsam Poplar, which is only seen near streams, and the little Rocky Mountain Maple (*Acer glabrum*) are the only trees of the coast forest of south-eastern Alaska, which is remarkable in its poverty of species, in its richness in individuals, and in the size these attain in the thin soil, a few inches deep at best, and often on the nearly perpendicular slopes of these glacier-swept hills. They are wonderful, too, in the deep mosses of the forest floor, and in their impenetrable undergrowth of Blue-berries of many varieties, Salmon-berries, *Menziesias*, and the terrible Devil's Club (*Panax horrida*), which so cover the ground with their entangled stems that travel through the woods is practically impossible. As compared with trees in forests further south, those of Alaska are not large, although Spruces and Hemlocks a hundred and fifty feet high, with trunks three or four feet in diameter, are not rare at the sea-level as far north as Baranof Island; ascending from the shore, however, the trees rapidly decrease in size and near the timber-line become small and stunted, as they often do at the sea-level at the heads of the numerous estuaries and fiords cut deeply into the mainland coast range. The deepest and most interesting of these fiords, the Lynn Canal, a narrow continuation of Chatham Strait, extends a hundred miles northward from the coast nearly to the sixtieth degree, and at its head is fed by the waters of the Chilkat, the Chilkoot and the Skagway rivers, swift mountain streams, which afford difficult passage across low passes into the interior to the headwaters of the great western tributary of the Yukon. The forests at the head of the Lynn Canal differ somewhat from those in the region nearer the coast. The narrow bottom-lands are covered with masses of Balsam Poplar or with the so-called Green Alder, which here becomes a tree fifty feet high. The Spruce is still abundant at the river-level and on the lower slopes, but it is everywhere small and stunted. The Hemlock also occurs here, but only sparingly, and not of large size. The Pine is seen on the flats and at considerable elevation on the hillsides, but here its leaves are broader than those of the coast trees, and it is passing into the variety *Murrayana* of the interior plateau, the Lodge-pole Pine of our northern Rocky Mountains. A White Birch is very common at low elevations, and is more like the Birches of Siberia and northern Japan than any described American species, and growing with it is *Acer glabrum*, which is certainly the most widely distributed of all the North American Maples, and probably the most boreal member of the genus, and Patton's Spruce is at the timber line. When these passes from the humid coast region to the dry interior are crossed an entirely different forest is encountered. The Hemlock and the Sitka Spruce have dis-

appeared, and the largest tree in the open scattered groves near the shores of Lake Bennett and Lake Linderman is a Fir (*Abies lasiocarpa*). With it grow stunted White Spruces (*Picea alba*), which in greater or lesser abundance and mingled with Balsam Poplars, Birches and Alders are scattered over the basins of the Yukon and its tributaries for hundreds of miles, and finally reach the Pacific coast on Kotzebue Sound within the Arctic Circle, and nearly five degrees north of Kadiak Island, where the forests of south-eastern Alaska give way to a growth of Grasses and low Alders and Willows.

Trees cannot be cut lawfully in Alaska for timber or fuel, for there is no law which permits the sales of stumpage or timber-lands, and no law relating in any way to the forest but the one which forbids all shipment of wood from the territory. There are a few sawmills in Alaska, however, and the number will soon be increased, and a large quantity of fire-wood is consumed at the salmon canneries and quartz mines, but the Government gets nothing for it, and is powerless to prevent damage to the public domain. Fortunately, the climate of south-eastern Alaska is so humid that forest fires are rare, and never very destructive, and reproduction is sure and rapid. These forests, therefore, even with American methods, will not soon or easily be destroyed; and here and to the southward along the coast ranges and islands of British Columbia through nine degrees of latitude from Cross Sound, at the north of Chicagof Island, to the Straits of Fuca is now the greatest continuous body of coniferous timber in the world, almost unmarked as yet by the axe, safe from fire and of easy access, from which the world will be able to draw great stores of material when the Redwoods and Douglas Spruces of the south have fallen, and our south-Atlantic and Gulf-shore pineries are only dim memories.

#### Pollen-bearing vs. Plant Vigor.

**I**N GARDEN AND FOREST, vol. x., page 38, an article with the above title recorded some experiments made at Cornell University during 1895-6. Other researches and tests have since been brought to a close and have thrown some further light upon the subject.

The idea that pollen production is more or less an exhaustive process has gained many adherents who maintain that, because, in animals, differences favorable to man appear after the operations of spaying and castration, it therefore follows that, in plants, similar results will also appear if the plants do not have to produce both pollen and seed or fruit. In proof of this theory the favorite example cited is the case of the Strawberry, in which it is claimed, and apparently with justice, that the pistillate varieties are more productive than the so-called staminate or hermaphrodites, which, in addition to the production of fruit, also produce pollen. And this fact is considered sufficient to account for the lightness of the crop borne by the staminate varieties. But, as will be seen later, it is just as probable that the unproductiveness of these hermaphrodites is the result of the theory they are now cited as examples to prove.

Pollen production undoubtedly does demand much of the plant's energy since it has been ascertained by analysis that this substance compares in complexity of composition with the seed. De Planta, Przybytek, Famintzin and Snyder have found the following substances in various kinds of pollen: Water, globulin, peptone, guanin, hypoxanthin, amides, saccharose, starch, fatty acids, cholestrine, resinous and waxy substances, coloring matters, potash, magnesium, calcium, phosphorus, sulphur, chlorine, iron, aluminium and manganese in varying quantities. Snyder's analyses of corn anthers after the shedding of the pollen, show much the same substances to be present in these empty husks. It is, therefore, easy to believe that large quantities of plant-food are required to produce these parts. Snyder remarks that if we allow "corn to be planted three feet six inches apart each way, and three stalks to the hill"

there would be 6.01 pounds of nitrogen alone per acre, "which makes the loss of nitrogen to the plant very considerable, equal to a very liberal application of nitrogen in the form of commercial fertilizers." But is this, strictly speaking, a loss? Has not the plant made provision for this apparent waste? These are questions that the experiments were conducted to test.

The primary office of pollen is to fertilize the ovules for the perpetuation of the species by seed. Since this fertilization depends upon such precarious agents as insects and the wind, plants which tended to produce even slightly more pollen than their fellows stood just that much better chance of perpetuating their characters—of having offspring. Allow this accidental trait to be perpetuated and augmented by heredity and the production of pollen becomes in time, as in the case of staminate dioecious plants, apparently the sole object of its existence. But in countless cases pollen is borne by the individual which also bears the fruit apparently without lessening the production of the latter, and even though the proportion of pollen approaches the highest figures of the dioecious males. Instances are recorded of Pine pollen being swept in quantity from the decks of vessels out of sight of land, and, again, of the beaches of our inland lakes and streams being yellowed by it. After many careful computations upon corn ovules and pollen grains, a writer finds that "allowing two ears of one thousand kernels each, to each plant (a very high estimate) there are still nine thousand pollen grains for every ovule to be fertilized." Darwin also records some interesting figures upon this point in his *Cross and Self-fertilization*.

The apparently great waste of energy in Corn-pollen production led to the apparently common practice in the last century of detasseling. This is recorded in *The New England Farmer*, 1797. Detasseling experiments have been tried at several of the experiment stations with contradictory results. In brief, it may be said that when the tassel was removed just as it appeared and before it had any chance to develop its pollen, there was sometimes a gain in the crop, but that when it was removed after the pollen began to shed there was no such gain.

Concerning the Strawberry so much has been said and written apparently without carefully conducted experiments, and by persons of more or less biased opinion, that the greater productivity of the pistillate varieties seems to be due to their sex, and even though the statements might be proved false, years would have to elapse before the popular mind could be shaken in its belief. After a careful compilation of all apparently reliable data obtainable from the various experiment-station reports and bulletins, it must be confessed that the pistillate varieties average higher than the staminate. This is found to be true no matter by what method the productiveness is judged, popular estimation, the scale of ten, weight or volume of crop, or of a certain number of berries. In only a very few instances do the individual staminate exceed the pistillates. These varieties are all of recent introduction. This excess never appears when a large number of each class are compared and calculated upon. Everything seems to warrant popular opinion. But it is believed that ever since Keens in England, and Longworth in America, impressed upon the horticultural public the importance of mixing hermaphrodite plants with the pistillate varieties to make the latter more productive, the staminate sorts have not had their due. The fact that the pistillates were productive when in proximity to the staminate was only a step to the theory that they were, per se, more productive, and that the ideal Strawberry must be a pistillate. It is true that the greater number of our more productive market sorts are pistillate, but it is interesting to note that the recently introduced staminate are close upon them. One reason that the staminate average so low is that a larger number of the old staminate varieties are retained than is the case with the pistillates, which are kept upon the move, so to speak. It is also true in this connection that the older

sorts in point of time have had greater chance to vary and deteriorate from their original type, due to differences in soil, culture and, as much as anything, to the different ideals of various growers. For example, the old Wilson as it originated probably does not now exist, if we may judge from the fact that of a number of samples of Wilson sent to Cornell Experiment Station a few seasons since, no two were enough alike to be called by one varietal name. It seems manifestly unfair to compare the old, run-out sorts, although bearing the original name and tracing their genealogy back to the original plant, with new, undeteriorated kinds. A comparison of old and new pistillate varieties reveals as great a range of productiveness as is found among the staminate. Hence the two classes should not be contrasted in the popular, unscientific manner since there is, after all these years of biased selection, no just basis for comparison.

In the experiments conducted at Cornell University all the plants were of as uniform development as possible, and in the cases where the plants were grown from cuttings, these were taken from individual specimens so as to reduce the factor of individuality to a minimum. The subjects were divided into three groups, as in 1896, the first blossoming naturally, the second suffering from emasculation in each alternate blossom, and the third being castrated in every flower.

The only annual which gave any results this season was the Alonzoa. The formation of its blossoms and its early and profuse flowering make it an exceptionally good subject to operate upon. The flowers may be opened and the stamens removed without injuring the development of the corolla. As with the Clarkia in 1896, the plants whose flowers were exsected produced several times more flowers and were more robust and vigorous than the non-exsected, while the "half-and-half" group was intermediate. Although practically even at the start, the exsected group had at the close a bushy development of axillary shoots which were covered with scores of tiny flower-buds. The natural group had hardly any of these side-shoots. It seems safe to conclude that Clarkia and Alonzoa find pollen-bearing an exhaustive process, and from these two cases we might further suppose that plants having a long period of bloom might show the effects of pollen production, while species with shorter blooming periods might, and probably would, show no effect at all.

Geranium and Nasturtium were the only cutting-grown plants which proved at all satisfactory. In each case the conclusions were much the same as given above. Nasturtium is a very useful subject since its stamens may be removed in a bunch with little danger of injuring the flower.

To summarize: Whether this production of pollen is the exhaustive process it seems to be, has yet to be proved. If it is exhaustive, it is reasonable to suppose that plants like the Corn, the Pine and others of their class would tend to reduce the amount of pollen produced and would expend their energies in other directions. On the other hand, it seems evident that the Strawberry has either found this process exhaustive and has thus tended to develop unisexual varieties, or that the increasing popularity of pistillate sorts as crop producers, which has presumably sprung from a misconception of the relative merits of the two classes, has led to biased care in selection—selection which has constantly tended to reduce the number of good staminate varieties at the same time augmenting the number and the attributes of the pistillates.

Again, if pollen production is exhaustive, it seems probable, as was stated above, that plants which have a long period of bloom would show the claimed evil effects very decidedly, whereas plants which blossom during only a short period and produce only a few flowers, would not show them. In other words, the minimum of evil should go with the minimum of blossoming both in time and quantity, and the maximum of depletion with the maximum of flowering. It is altogether probable, however, that if the process is depletive, it has been, is being, and will be

answered by each species for itself, so that it will at no time exceed the plant's powers. By the law of natural selection, that species which would perpetuate itself must conserve all its force or become extinct.

#### Baron Von Mueller's Services to California.

MANY times since the death of Baron Ferdinand Von Mueller, the Australian botanist, I have regretted that his friends and correspondents in California did not long ago make some public and especial acknowledgment of his great services. It is true that these services were widely appreciated, and that he often received evidences of the affection he inspired, but the fact remains that his work for California was so remarkable that it deserves public recognition. If state legislatures were sensible of such benefits as Baron Von Mueller rendered this state they would take pleasure in passing resolutions to show their appreciation of this and similar services.

My own correspondence with this lovable man commenced more than twenty years ago, and continued at intervals until his death. In this correspondence the benefits were chiefly on one side, for the few notes upon plant-life that I could offer and the small collections of Pacific coast seeds that I occasionally sent him were unworthy of comparison with his lavish and thoughtful gifts. It was plain that he loved with all his heart to extend the culture of trees and plants and that he took a personal interest in each correspondent. It seemed, too, that he had acquired much knowledge of our California conditions, and felt himself responsible in some degree for the horticultural development of our state. In the course of a wide correspondence with botanists, collectors and various officials in different parts of the world, I may say that I have never met any person who was more unselfishly interested in the work of plant distribution.

Baron Von Mueller's interest in California matters led him to carry on a correspondence with several hundred of our leading florists, gardeners, nurserymen, collectors and amateur horticulturists. This correspondence extended through so many years and his letters were so invariably accompanied by packets of seeds that trees and plants from his distribution are now to be found in every part of California. Wherever one sees a plant which is not generally known he is likely to find, upon inquiry, that the seed came from Baron Von Mueller.

It would, of course, be expected that our older collections of Eucalypts and Acacias were largely created through his coöperation, but it is a surprise to find that he not only gave California its oldest specimens of leading Australian species, but that we received from him many species from south Africa, India and other parts of the world where he had correspondents. Under his management the Melbourne Botanic Garden became a kind of international clearing-house for the rarest seeds many years before they were common in the trade.

A list of species naturalized in California through the efforts of this one botanist would be much too long to print here. I believe, however, that such a list would include the leading Casuarinas, all our more valuable Atriplexes, many brilliant shrubs now comparatively common here, Araucaria Bidwilli, Aberia caffra, and fully fifteen species of Acacias and Eucalypts. I know of several fine Hakeas grown from seed sent by him many years ago. This summer Mr. G. P. Rixford, of San Francisco, after sixteen years of waiting, bloomed a noble Iris (*I. Robinsoniana*) from one of five seeds received from Baron Von Mueller. This plant is figured on page 255 of the current volume of GARDEN AND FOREST. Perhaps for years to come new species of plants will be arriving at maturity here, to strengthen our grateful memory of this old botanist.

In later years the Baron had a habit of placing certain favorite seeds in every consignment. All his packages, which once were rather conventional as regards appear-

ance, became more and more unconventional, until most of them utilized various kinds of empty tobacco bags. Not long ago I received a side light upon this subject from a much-traveled English woman, who said: "I was once for several days on a steamer with Von Mueller. He was going off to a camp in some wilderness and was dressed like a laborer. He sat on the deck all day, looking at the sky and ocean and smoking a little old black pipe, with tobacco bags in each of his pockets. He seemed very good-tempered, but he did not strike me as clever, though I heard he was a famous man."

A picture of the Baron in his Sunday best, decorated with medals of honor, hangs in the botanical department of the University of California, and a lovable face it is. But I like best to think of him in old clothes, smoking the little pipe, and going off into the wonderful Australian forests.

## Foreign Correspondence.

### Nepenthes.

MR. HARRY J. VEITCH read a valuable paper on *Nepenthes* at the last meeting of the Royal Horticultural Society. A selection of species and hybrids was exhibited from the famous Chelsea collection, which for many years has been admittedly the best in England, if not in the world. Messrs. Veitch & Sons were the first among the nurserymen to collect these plants, and most of the hybrids now in cultivation were raised in their nursery.

Commencing with the history of the genus, Mr. Veitch traced the discovery of the various species. The first known was *Nepenthes Madagascariensis*, a comparatively unattractive species, which singularly enough was one of the last to be introduced, Messrs. Veitch having obtained plants of it for the first time in 1878. About thirty species are known and these are found principally in Malaya. The pre-Linnæan name for the genus was *Mirabilis*, Linnæus, who knew only *N. distillatoria*, renaming it *Nepenthes*, "Freeing from Grief," and stating that "if this is not Helen's *Nepenthe* it certainly will be for all botanists."

*Nepenthes Rafflesiana* was introduced to Kew in 1845. This was followed by the closely allied *N. Hookeri*, introduced by Messrs. Low & Co. in 1847. Then Messrs. Veitch sent a collector in search of *Nepenthes*, and various species were thus obtained by them. The discovery of four wonderful species in Borneo by Sir Hugh Low led to the preparation of a classical paper on *Nepenthes* by Sir Joseph Hooker, which was published in the *Transactions of the Linnæan Society* in 1859. A few years later these and other insectivorous plants were the subject of Sir Joseph's Presidential Address to the Linnæan Society, and this, with Darwin's work on the same subject, gave these plants an interest for horticulturists and for the laity which they have ever since maintained.

The four largest species are *Nepenthes Rajah*, *N. Edwardsiana*, *N. Lowii* and *N. villosa*. These are all wild on the mountain of Kina Balu, in Borneo, where, according to Mr. Burbidge, the natural conditions as regards temperature and moisture are somewhat peculiar. This may account for the failure of cultivators with three of these species. The only one successfully cultivated so far is *N. Rajah*, and this is only grown at Glasnevin, where Mr. Moore has always kept it in a cool house along with *Masdevallias*. A pitcher taken from his plant, shown by Mr. Veitch, astonished everybody by its size, vigor and rich colors; it would probably hold a pint of water. Another species, *N. Edwardsiana*, has pitchers twenty-two inches long and capable of holding two quarts of water. The size of these pitchers can be understood when it is stated that a drowned rat was found in one of them by Sir Hugh Low.

By the year 1872 ten species of *Nepenthes* had been successfully established in gardens here and four hybrids had been raised. The first of these was *Dominiana*, raised in Messrs. Veitch's nursery in 1862. The introduction of *N.*

*sanguinea*, *N. Veitchii*, *N. Curtisii*, *N. Burkei* and *N. Northiana* has added considerably to the popularity of the genus, and as numerous hybrids have been raised from these the variety of pitchers has been greatly increased. The best of all hybrids is *N. Mastersiana*, raised by Messrs. Veitch & Sons from *sanguinea* and *Khasyana*. It is easily cultivated, is dwarf in habit, pitchers freely, and the pitchers are large and of a dull crimson color. Next to this come *N. mixta* and *N. Dicksoniana*, the latter a hybrid between *N. Rafflesiana* and *N. Veitchii*. *N. Morgania*, a hybrid of American origin, is also highly appreciated here.

There are, according to Mr. Veitch, over forty hybrids enumerated, but some of these are merely variations of the same hybrid, much variation being shown by plants out of the same batch of seedlings. It is probable also that some of these so-called hybrids have been obtained by crossing varieties with each other. The introduction of *N. Northiana* was due to the enterprise of Mr. Veitch, who on seeing in 1880 a painting of it which Miss North had made from a plant brought to her by a native when in north-eastern Borneo, obtained particulars from her and despatched a collector for it. He found it growing below the ledge of a cliff and succeeded in getting home seeds of it. Mr. Veitch says it has proved one of the most tractable of the *Nepenthes* under cultivation and one of the handsomest. A recent introduction from the Seychelles, namely, *N. Pervillei*, was exhibited from Kew, where it has been raised from seeds. It is remarkable for the length of the pitcher-stalks and for the elegance and rich coppery-red color of its pitchers. This species has always been a special desideratum with botanists as well as cultivators, and it has taken twenty-five years to get it successfully introduced. Plants of *Nepenthes* rarely recover from the effects of a long ocean voyage, while the seeds are so easily damaged that one may try time after time and fail.

The seeds ripen in about three months after fertilization, and germinate in about six weeks. The first leaves after the cotyledons invariably bear tiny pitchers. Some species are said to bear only tiny pitchers and no leaf-blade when young. With good treatment plants twelve months old have leaves four inches long and pitchers an inch long. The stronger-growing sorts grow from three to four feet in a season and produce from twelve to eighteen pitchers. The best pitchers are produced by basal shoots or short plants, and for this reason cultivators prevent the plants from making long shoots by pinching the tops out of them when about a foot long. If allowed to grow the stems will attain a length of twenty or even thirty feet. The pitchers developed on long stems are smaller, narrow at the base and less highly colored than those on short stems. There is not much variation in the leaf characters of the genus, some being longer and narrower in the blade than others. They are all strap-shaped, leathery in texture, green, and the pitchers are suspended on stalks formed by the prolongation of the midrib of the leaf. This stalk performs the duties of a tendril, twisting round a twig in precisely the same way. By this means the plants in a wild state succeed in climbing up into sunlight. It is noteworthy that the species which produce the largest pitchers grow at a high altitude where the conditions are subtropical or even temperate. According to Mr. Burbidge these species are always terrestrial, comparatively short in stem, and their pitchers usually rest on the ground. The same authority stated that in Borneo these plants are known as Monkeys' Cooking-pots and that the natives drink the liquid found inside the pitchers before they open, as a cure for indigestion. All the species are insular in habitat, and they are mostly local, the exception being *Nepenthes gracilis*, which is found all over Malasia.

The following selection of species and hybrids represents what are here considered the best for the garden: Species: *Burkei*, *Curtisii*, *distillatoria*, *hirsuta*, *Northiana*, *Rafflesiana*, *sanguinea* and *Veitchii*. Hybrids: *Amesiana*, *Dicksoniana*, *Mastersiana*, *mixta*, *Morgania*, *Sedeni* and the new *Tiveyi*. This last was shown for the first time

Fig. 49.—*Rhus trichocarpa*.—See page 384.

1. A flowering panicle, natural size. 2. A fruiting branch, natural size. 3. A staminate flower, enlarged. 4. Stone of a fruit, enlarged.

this week by Messrs. Veitch. It is named in compliment to their grower of Nepenthes, Mr. Tivey. It is a hybrid between *N. Veitchii* and *N. Curtisii*, and resembles the latter, but the pitchers are paler in color and have the wide rim of those of *N. Veitchii*. It was awarded a first-class certificate.

London.

W. Watson.

## New or Little-known Plants.

### *Rhus trichocarpa*.

**R**HUS TRICHOCARPA\* (see illustration on page 383 of this issue) is a slender tree frequently twenty-five feet in height and a native of Japan, where it is a common forest plant in Yezo and in the mountain regions of central Hondo, where it also often springs up in hedgerows. The leaves are eighteen or twenty inches long, unequally pinnate, with dark red-purple midribs and usually thirteen broadly ovate, long-pointed, short-stalked membranaceous leaflets, hirsute below, especially on the stout midribs and primary veins, from three to five and a half inches long and from an inch and a half to two inches wide. The flowers are produced in narrow erect panicles, appearing in early summer, and are soon followed by the pale prickly fruit borne in loose drooping clusters. The habit of this tree is not particularly good, and its flowers and fruits are not attractive, but in the autumn it lights up the Japanese forest with splendid tints of orange and scarlet which are not surpassed in brilliancy by those of many other plants. Introduced into the Arnold Arboretum five years ago, *Rhus trichocarpa* has proved perfectly hardy up to this time in eastern Massachusetts, and this year has flowered and produced its fruit for the first time.

### Raspberry, Bunyard's Superlative.

**I** WAS surprised to find two years ago how good a fruit this is as grown in English gardens, and was at once ambitious to try it in the conditions of our New England climate. A hundred young canes were obtained and these we have fruited in the past two seasons. We are satisfied that there are few, if any, Raspberries to equal this for size and flavor. This impression also finds favor with Messrs. Ellwanger & Barry, who have about 40,000 plants of this Raspberry in their grounds, soon to be distributed. The canes are very stout and rigid, so that no staking seems to be required; the berries are abundant, and so large that they are often coxcomb-shaped like some strawberries. The fruit bears transportation better than that of many of the smaller varieties. Messrs. Ellwanger & Barry assure me that this variety is as hardy as any they grow, and much harder than some others of native origin. This statement is reassuring, for we have covered our canes with earth each winter to make sure of them, as is necessary in this section with all the other varieties to obtain a crop. Many kinds are under trial here to find out which is the best. We have most interest in a lot that are the result of two large berries taken when ripe in the summer of 1896, rubbed out in fine dry sand and sowed at once. The seed pans were frozen early last winter and brought into warmth the beginning of the year, when the seeds at once came up. From this seed we have now more than two hundred fine young canes, averaging four feet in height and still growing. These plants, we think, are the result of a cross between the Cuthbert and Superlative Raspberries, as these two kinds grew together and bees were plentiful. Great variation is apparent in the habit of the seedling canes, and we shall watch with interest their fruiting next summer. There is yet much scope for improvement in Raspberries; none are hardy enough, the habit of many, especially the new Columbian, is very distressing when one has to pick the fruit, and afterward when the new growth is so far advanced as to become prostrate.

As already stated, Raspberry canes require protection in this section by laying them down and covering them with earth in the fall. One season the frost came early and continued, and the canes could not be laid down in the usual way. Loose

straw litter was strewed over them after they were laid on the level. This plan was only tried once, as the field mice congregated apparently from the whole county, and in spring not one cane was left ungirdled. There were no Raspberries that summer.

South Lancaster, Mass.

## The Cultivation of Cannas.

**I**T is interesting to look back a decade and note the progress made in the cultivation of Cannas. The development of the Crozy type, from which almost every high-class variety has come, is most interesting. In no class of plants can less credit be claimed by the hybridist, for the best Cannas have resulted from careful selection. The arrangements for close fertilization are so complete that it is almost impossible, if fecundation is secured, to thwart Nature. It was predicted when the large-flowered giants of the Flaccida type, Italia and Austria, were introduced that they would supersede the Crozy type. Both these types are continuous bloomers, but what is lacking in the blooms of all Cannas, durability of texture, is still more lacking in the Italian varieties. The flowers are extremely fugacious, and what I have seen of the half a dozen or more new colors in this section they all have the same defect. The American variety of this type, the Burbank, is no better in this respect; in appearance it resembles the variety named Austria.

As pot-plants for foliage effects Cannas are highly effective, and under glass, with shade, the flowers are more durable. This is true of all Cannas; under glass the flowers have better individual development and last long enough to fill out a good round truss. Canna specialists hesitate to judge a variety by its behavior under glass; the supreme test is out in the open air. Paul Briant is superb under glass, but of little use under direct sunlight. For a bedding Canna a compact truss is a strong recommendation. Among medium growers, Queen Charlotte and its "improved" variety are the finest. The flowers are widely banded with yellow and durable. An effective combination in a circular bed may be made with plants of Queen Charlotte in the middle and Mrs. Fairman Rogers, a fine form of the Crozy type, as an edging. Mr. Denys Zirngiebel, of Needham, Massachusetts, who makes a specialty of Cannas, considers President Cleveland, a salmon-scarlet, the finest bedding Canna of its color yet introduced. It is very compact, and in vividness of coloring it outshone all others in a large patch containing sixty varieties. It was raised by Mr. Pfister, gardener at the White House. This list comprises scarcely half a dozen first-class varieties, if the dark-leaved sorts are excluded. Bismarck, a recent variety, showed up well; it has a dwarf habit and compact and full-flowered truss of crimson flowers. Robert Christie is a beautiful salmon-red and a splendid pot-plant; Ami Pichon is a good maroon with deeper spots; Leonard Vaughan is a fine dark-leaved kind with scarlet flowers; J. D. Cabos has orange-scarlet blooms; President Carnot has luxuriant foliage.

Wellesley, Mass.

T. D. Hatfield.

## Notes on the Orchid-flowering Cannas.

**W**E have been greatly interested in the new Orchid-flowering Cannas since their first announcement, and have taken some pains to grow most of the varieties offered for sale. A note regarding the variety America was sent to GARDEN AND FOREST some weeks ago (see vol. x., page 178), and a completer account has been more recently published in the *Tenth Annual Report of the Vermont Experiment Station*, page 119. Since that report went to press we have brought two new varieties of these Cannas into blossom. These are Bavaria and Burgundia, both from the lists of Dammann & Co., the originators of Italia, Austria and America.

We are somewhat disappointed in these two newest varieties, not because of bad qualities, but on account of their close resemblance to Italia. Italia is a beautiful Canna, to be sure, perhaps the best one of this class yet introduced, but Burgundia and Bavaria are so much like it that a careless observer would pass them by as all of the same kind.

Both varieties are, however, of smaller stature than Italia and have smaller foliage. The flowers in all three are of a brilliant canary-yellow upon which two shades of rich apricot-red are successively overlaid. In Italia the red colors are run together in the throat to make somewhat regular solid blotches bordered with very deep bands of the clear yellow, like an exaggerated Queen Charlotte. In Bavaria there is very little of the darker red shade, while the lighter red is scattered in small dots well out upon the petal-like staminodia, giving an effect more like that of Florence Vaughan. Burgundia is almost a medium between Bavaria and Italia, with more of the dark

\* Miquel, *Ann. Mus. Bot. Lugd. Bat.*, ii., 84 (1865) (*Prodr. Fl. Jap.*, 16).—Franchet & Savatier, *Enum. Pl. Jap.*, i., 93.—Engler, *De Candolle Monogr. Phaner.*, iv., 379.—Sargent, *Forest Fl. Jap.*, 34.

overlying red than the former, and more of the leopard spottings than in the latter. Burbank, the only variety of American origin yet advertised, does not seem to have been noted so much in the horticultural press as its good qualities deserve. It is the equal of the Italian varieties. The flowers have the form of Italia and nearly the coloring of Austria. That is to say their form is the best, and their coloring pure canary-yellow with a few faint reddish spots in the throat.

These new Cannas, hybrids of Madame Crozy with *C. flaccida*, are especially admirable for two qualities, namely, the perfection of form and the richness of color in their blossoms. The type of Canna-flower which we are used to seeing among the French dwarfs, when taken by itself, is singularly inharmonious and unsatisfying in its outlines, but there is a fullness of form and grace of outline among the Orchid-flowering sorts which by comparison is altogether pleasing. Their richness of coloring is remarkable. The comparative size of the flowers has been considerably overstated in the advertisements. They are quite large enough, to be sure, but they are only a little larger in fact than Charles Henderson, Alphonse Bouvier, or dozens of other old and well-known varieties.

Several of these varieties we have had this year in quantities sufficient for liberal use in outdoor beds. Their large, luxuriant, Musa-like foliage is quite effective, but there is a noticeable paucity of flowers in comparison with the older French dwarf sorts. The softness and flaccidity of the blossoms detract somewhat, of course, from their usefulness out-of-doors, but not so seriously as we had expected. The flower-spikes, though comparatively few in number, are fairly durable and effective as far as they go.

The Orchid-flowering Cannas—and, by the way, they ought to have a better class name—are certainly attractive novelties for the amateur, but in their present state they are not likely to find great favor among professional gardeners, who are interested chiefly in gaudy red and yellow floral effects.

University of Vermont.

F. A. Waugh.

[The Italian hybrids noted grow strongly in this latitude, their principal defect being that their flowers scorch under our summer sun, and they are for this reason not as effective as the size of the flowers would indicate.—Ed.]

### Hot-house Palms.

AMONG the Palms which require a warm temperature, *Stevensonia grandifolia* is one of the handsomest. It is most attractive when the plants are from two to eight years old. There are apparently two distinct forms of this species, one has leaves uniformly green, and in the other form they are dotted with a reddish yellow color.

*Pinanga Kuhlii* is a rapid grower and reaches the fruiting stage in about four or five years; so far as I know it is only exceeded in this respect by *Geonoma fenestrata*. *P. Kuhlii* must have a moist, warm atmosphere. The leaves are quite large, with from eight to fifteen pairs of irregular pinnæ. The fruit is rather ornamental, at first yellow, changing to a dark purple when ripe. Old plants send out growths from the base of the stem. This is a desirable species for planting out in a conservatory.

*Hyophorbe amaricaulis* is pleasing when young, and the same may be said of *H. Verschaffeltii*. It is difficult, however, to keep them in good condition when they become a few feet high. The last-named species was very popular twenty years ago as a decorative plant, but has been displaced by the *Kentias* and by *Areca lutescens*.

*Acanthophoenix crinita* and the variety *Herbstii* are neat-growing, small-sized Palms. The leaves are pinnate, the pinnæ arching toward the ends. This species suffers quickly if the soil in which it is growing is allowed to become dry.

*Ceroxylon niveum*, one of the Wax Palms, can scarcely be said to be ornamental when young, for the leaves are coarse and undivided. As it grows, however, it becomes highly ornamental. The long, feathery leaves are grayish green. Although it will thrive in the temperature of an intermediate house, it puts on a more graceful appearance when given stove temperature.

*Latania Commersonii* has immense palmate leaves, and is only fit for botanical collections.

*Livistona Jenkinsii* is an Indian species of great beauty when a few feet high. In young plants the leaves are irregular in shape; in adult plants they lose this peculiarity. The leaves have a bright, almost emerald-green color not found in any other species of *Livistona*. *L. rotundifolia* resembles *L. Jenkinsii* somewhat, but is smaller in all its parts. In young plants

the leaves are closely arranged together with short stalks; the leaf-blades are completely round, with about sixty divisions. This Palm is rapidly becoming popular as a decorative plant and is being largely grown by some dealers.

*Licuala grandis* is cut up in the ends of the leaves for a short length, thus giving the plant a fuller, rounded appearance than that of other Fan Palm. It needs a hot, moist atmosphere or it is liable to become infested with red spider.

*Calamus Lewisiaanus*, *C. fissus* and *C. palembanicus* are ornamental Palms with graceful pinnate leaves. They are only suitable for conservatories with plenty of head room, as they grow tall.

*Arenga saccharifera* has immense pinnate leaves of a dull green color. It is only useful in large houses.

*Euterpe edulis* is probably the handsomest of all the feather-leaved Palms, and should be in every collection. It has the same habit of growth as *Seaforthia elegans*, but the leaves are smaller and more compact. Plants fifty feet high have stems only a few inches in diameter.

Botanic Garden, Washington, D. C.

G. W. Oliver.

### Notes on Propagation.

MANY tender foliage plants make their most rapid growth during the latter part of the summer. The root-action of the parent plant is then free; it is therefore easy to root cuttings. For example, *Crotons* can be rooted easily at this season by using the topping method, frequently practiced for *Ficus*. This method is the most satisfactory one for strong and highly colored growths, from the fact that little or no foliage need be lost, as may be the case when a strong and sappy growth is at once removed from the parent plant for cutting purposes. Large *Dracænas* may also be similarly topped with the loss of but few leaves, and the young plants thus secured have the advantage of large leaves at the bottom and make more symmetrical specimens for the next season. Old plants of *Yucca quadricolor* that have become unsightly from the loss of their lower leaves may also be renewed by topping. For these plants it is advisable to nick the stem quite deeply, and the bandage of moss used need not be kept quite as wet as is necessary for *Crotons* or *Dracænas*. After the removal of the top from an old *Yucca* the stump may be kept rather dry for a time to avoid decay, when other breaks will appear and furnish new stock, in addition to the suckers that are likely to show from the roots.

Cuttings of such easily managed plants as *Sonerilas*, *Bertolonias* and *Fittonias* may be rooted at almost any season, and it is not too late now to increase the number of these plants. The most effective way of using low-growing plants of this character is to group a number together in an eight or ten inch pan filled with a rather light and well-drained compost.

Small side-shoots of *Cyanophyllum magnificum* and *Sphærogyne latifolia* make satisfactory cuttings, which should be kept rather close and warm in a propagating-frame to insure their rooting. The best medium for rooting them is a mixture of cocoa-fibre and sand. Single-eye cuttings of these plants also root readily, but do not always make as shapely specimens as the side-shoot cuttings, and sometimes refuse to start away promptly. A well-colored specimen of the Variegated Pineapple is among the most effective of stove-plants. The crown of a fruiting plant provides the best cutting material, and will root freely in pure sand if placed in a light position in a warm house and given but little water. Young plants may also be secured from sections of the stem of a rather leggy specimen. These sections should have the cut surfaces dipped in slaked lime to prevent decay, and then be half-buried in sand and treated like top cuttings.

*Pandanus Veitchii* has no special season for propagation, but cuttings planted in cocoa-fibre will root quickly during the latter part of the summer and early fall. The cuttings should be kept somewhat dry.

The propagation of *Nepenthes* is comparatively easy in a warm propagating frame; the only exception to this rule is found among those species having hirsute leaves, of which *N. lanata* and *N. villosa* are types. Small, short-jointed side shoots of *Nepenthes* are the best cuttings and usually produce the finest pitchers. An open mixture of rough peat and sphagnum moss is the best material in which to root them. The cuttings must never become dry, for once they seldom recover.

Success in the propagation of tender species depends also upon the after treatment of the newly-rooted plants. In most instances the safest plan is to return the young plants to the cutting frame for a week or two after they have been potted off and gradually give them more air as the roots become

established in the new soil. They should finally be removed to permanent quarters as they begin to grow. These details of management are, however, the most difficult lessons to learn in the work of propagating.

Holmesburg, Pa.

### Sternbergias.

**STERNBERGIA MACRANTHA**, which was reported last year as flowering much later in the season, opened its first flower in the middle of September, and its blossoming time is evidently about that of *S. lutea*, which is now in full bloom. *S. macrantha*, as its name indicates, has a large flower about twice the size of that of *S. lutea*, but one misses the foliage which only appears in late winter, and unless *S. macrantha* is grown under a mat of some low-growing plant it misses much of its effectiveness. This species was collected a few years ago by Mr. Whittall, who introduced it to cultivation.

*Sternbergia lutea*, which has a strong tradition of being the Lily of the Field, is certainly one of the most cheerful and attractive of the low-growing small flowers. The common name of Winter Daffodil is not as inapt as popular names often are, for it somewhat repeats the spring effect of yellow Daffodils, with golden-yellow flowers and plentiful foliage to enhance its charms. The flowers show their full charms only to the sun.

Elizabeth, N. J.

J. N. Gerard.

### Calochorti in a Southern California Garden.

**DURING** the past season I have had much pleasure in cultivating Calochorti in the garden. In a good collection the season of bloom here continues from the first of March to the middle of July. The first species to open is *C. Catalinæ*, with large white flowers, shaded lightly with purple on the outside and with deep wine-colored spots at the base of the petals. It continues in bloom for two months. A rare and lovely form is *C. Catalinæ alba*, with pure white flowers and no trace of purple, but small yellow spots at the base of the petals. *C. Catalinæ* is in flower for two months. Before it is done *C. clavatus* appears, and this, in my opinion, is the finest of all the yellow-flowering kinds. A year ago I wrote to GARDEN AND FOREST (see vol ix., p. 249) in praise of *C. luteus concolor*. I have since found that I was in error and that the plant described was *C. clavatus*. These flowers are often four inches in diameter, of the richest golden-yellow, with rich brown markings in the centre. Occasional plants bear pure yellow flowers. The plant is robust and easy to grow in any soil. About the same time flowers of *C. venustus* and its varieties appear. *C. venustus roseus* has charming pink flowers. Some of the *venustus* El Dorado varieties are fine, and one having rich wine-red flowers was conspicuous.

Even here the desert species are difficult to grow outside of their habitats. My best success with *Calochortus Kennedyi* was in boxes of decayed granite soil brought from the mountains. The flowers of this species are unique in color, being of the richest orange-scarlet, with purple spots in the centre. *C. Weedii* and *C. venustus citrinus* bear interesting flowers, but they cannot compare in beauty with those of *C. clavatus*. The last species to bloom is *C. Plummeræ*; the flowers are large, in color rich lavender-purple and lined with yellow hairs. It continues in flower quite into July. *C. luteus*, *C. albus* and *C. amœnus* are interesting, but to my mind not so fine as the true Mariposa Lilies.

Los Angeles, Calif.

E. D. Sturtevant.

## Correspondence.

### Notes from Missouri.

To the Editor of GARDEN AND FOREST:

Sir,—After favorable weather in spring and early summer throughout this section came the unwelcome change of a drought, and week after week the earth was scorched. The dust was bottomless and the meadows have been brown as in winter. Here and there on rocky hillsides great patches of trees are apparently dying, and every leaf hangs crisp and sere from the shriveled twigs. Early in September I noticed Peach and Pear-trees growing in thin, hard soil, with the fruit actually shriveling upon the trees. Should this drought be followed by a severe winter thousands of fruit-trees in this state will die, for experience has repeatedly demonstrated that imperfectly developed and prematurely ripened wood has low vitality; seasons such as this are vivid object-lessons, showing the need of extra care in planting.

Vegetation has by no means suffered alike. Flowers, vegetables and young trees planted in ground that was well pre-

pared found encouragement for early and deep growth; while these have languished, they have borne the drought well and have attained fair development. Trees that have been pruned and mulched, and in the case of fruit-trees, had the fruit thinned so as not to tax the tree's vitality, withstood the trying heat well. In the third week in September we picked pears, peaches, grapes and apples of fair size and smooth and free from blemish. A popular belief exists that it does not pay to grow fruit extensively in a climate subject to drought. It is more reasonable to protest against neglecting fruit-trees in a country liable to dry summer seasons. Nature has given this south-western country a soil and climate peculiarly adapted to the production of large and highly-flavored fruit. Even in this drought I have seen peaches half of which would not go through the mouth of an ordinary Mason fruit-jar, and in favorable seasons pears weighing twenty-two ounces and plums measuring six inches in circumference have been grown here. But such fruit does not grow promiscuously. Overcropped trees, or those left to the mercies of the apple-borer and codling moth, give but common fruit in the most favorable seasons; in trying seasons such as this they are all but failures. Our most productive Pear and Plum-trees are mulched, and I believe this care pays in dollars and cents.

The flowers at Oak Lawn withstood the dry heat remarkably well. A threatened failure of water-supply cut off the use of the hose except for a few potted and special plants. The closely shorn sward of the lawn has been distressingly brown, and the contents of several flower-beds have succumbed. Nevertheless, there are many plants yet in full bloom, even where the sun has shone fiercest and hottest. I can account for it in no other way except that the beds are deep and mellow and the plants have grown large enough to shade the ground and prevent surface evaporation, while their roots have struck deep enough into the earth to find moisture. Roses, Cannas, Cockscombs, Phlox, Snapdragons, Dahlias, Petunias, Portulacas and Marigolds have done best among flowering plants, though a score more have given a few scattering blossoms. Vines of all kinds have been unusually luxuriant, and Passifloras, Manettias, Ipomœas, etc., have flowered luxuriantly. My experience is more and more in favor of vines, shrubs, perennials and tuberous plants for ornamental purposes in countries subject to dry weather. Annuals and bedding plants should be planted in situations which are in shade a part of the day or in the shelter of some building. Double the display of flowers may be had for the same expenditure of labor and money if good judgment is used in selecting and planting.

Pineville, Mo.

Lora S. La Mance.

### A Missouri Fruit-farm.

To the Editor of GARDEN AND FOREST:

Sir,—The Olden Fruit Farm, to which reference was made last week in my notes from the Ozark region, now comprises three thousand acres. This tract was mostly virgin soil, and covered with the native tree growth which is largely made up of Black Jack Oak, when the farm was established between thirteen and fourteen years ago. But it also includes several outlying farms of much older origin, all of them having Peach and Apple orchards, some now thirty years old. The condition of these orchards aided Colonel J. C. Evans, the experienced fruit grower, who founded the "greater Olden Fruit Farm," and who still controls it, in deciding on a suitable location for his enlarged enterprise. This large farm takes its name from a pioneer fruit grower named Olden, who owned the old place that became the nucleus of the present great undertaking.

Altogether there are 105,000 Peach-trees on the place. Among the large proportion of Elberta trees there is one block of 12,800 trees of that popular variety. Of these about 75,000 are in bearing.

The average expense of starting a new Peach or Apple orchard is given by Superintendent Mosely, of the Olden Fruit Farm, as follows: Cutting off the trees, known locally as slashing, \$3.00 an acre; clearing and burning, \$1.00; grub breaking, \$3.50; picking and burning stumps and roots, \$2.50; stock, \$7.00, or about four cents apiece for either Peach or Apple-trees.

Peaches are invariably set on the highest ground in the Ozark region, as the position largely exempts them from the danger of late spring frosts. Apple orchards occupy the dipping intervals. In many orchards Peach and Apple-trees are set alternately, with the idea that the Peach-trees will have reached the limit of profitable bearing by the time they crowd the Apple-trees. But this plan is neither followed nor approved on the Olden farm, where that limit is not yet estab-

lished, for the thirty-year-old trees on the old, original farms still give profitable crops as regularly as the younger trees. Corn is grown between the fruit-trees. This crop, which averages twenty-five bushels to the acre, is fed to hogs, and this proves the most profitable way to occupy the ground while the orchards are maturing. It is stated that at least one carload of hogs is shipped from the Olden farm every week in the year.

This farm is well equipped for utilizing its enormous fruit crop. Large shipments of fresh fruits are made by rail daily, and there is a small but complete canning plant with a capacity of 5,000 cans a day, the output of which it is expected will this year reach 50,000 cans, or eight carloads. There is also a modern distillery with a capacity of twenty barrels a day, where all surplus or inferior peaches and apples are made into brandy of the highest grade, and where the entire crop from forty acres of Blackberries is also consumed.

The red, gravelly soil of the Ozark fruit region looks unpromising in itself, and it is in many places closely covered with a really forbidding and formidable covering of rocks or stones, ranging in size from that of an egg to a loaf of bread. These do not seem to interfere greatly with plowing, as the stones are seemingly all on the surface and slide to one side. They are considered an actual advantage to the orchards in that they act as a mulch, and keep the ground cool and retain moisture near the surface. Both orchards and crops on the soil so mulched endure drought better than on ground that is free from stones.

Brighton, Ill.

Fanny Copley Seavey.

### A Wet Season.

To the Editor of GARDEN AND FOREST:

Sir,—A wet season affords a special opportunity to note the differences and the compensations of various soils and situations. In every place of any extent, especially where the surface is varied, there is some variety in this respect. Skill in adaptation will show a surprising effect in the results. It is the taking advantage of these slight helps that may mean success or failure. Walking about the grounds of a friend this summer I came upon a broad sheet of Forget-me-nots, which filled a hollow near the outlet of an attractive little pond, used for supplying ice. My friend explained that she had tried to establish a large bed of *Myosotis* in her garden three times and failed; then this spot was selected and proved a place where the plants were perfectly at home, and they grew and flowered and spread with the utmost luxuriance.

Flowering and fruiting plants that require a large supply of water and those which resent an excess of water are clearly differentiated in a season like the one just closing. From notes taken in a garden of fruits and flowers, which includes four or five acres of varied surface, both the gains and the losses of such a season appear.

Perennials generally have done only moderately well. Hardy Chrysanthemums, perennial Phloxes and some others have mildewed badly. Annuals, on the contrary, have given profuse and persistent bloom. Shrubs have made unusual growth. Out of a tolerably full collection of the most reliable hardy shrubs, set within five years, only a small proportion made satisfactory growth during the three preceding dry summers. But with liberal mulching the roots have done better than the wood, apparently, and this year the copious rains have induced a rapid production of vigorous shoots.

Vegetables, especially root crops, succeeded well in a soil naturally light and dry.

Early peaches rotted so badly this year that an almost total loss of the large crop is the result. Late varieties did well.

Details vary, and everywhere the gardener who looks for lasting results needs to study the capabilities of the actual situation, but the suggestions of a wet season may be turned to account in a dry one, if there is at command that most important auxiliary, an adequate and easily controlled water-supply.

Amherst, Mass.

D. H. R. Goodale.

### Insects in the Garden.

To the Editor of GARDEN AND FOREST:

Sir,—In passing a fine specimen of the rare and beautiful Yellow-wood I was surprised to note that it was badly attacked near the ground by what appeared to be some relation of the Locust-borer. I have frequently thought that we shall have to make the destruction of insects as regular a part of systematic gardening as the destruction of weeds. At present there is little account taken of insects by most owners of gardens. Rotten peaches are seen, but it never occurs to the grower to

look inside for the larva of the curculio ready to emerge. The damage is supposed to be the result of something mysterious, and perhaps some editor is written to for a solution of the puzzle. We may go into one of many gardens and see the leaf-worm at work before the owner's eyes, who is in utter ignorance that an insect is on hand. It is not uncommon to see beautiful and rare evergreens utterly destroyed by this curious and active creature. In some seasons certain insects are more damaging than others. This year the red spider has been singularly destructive of evergreens, and the honey aphid of Norway Maple and other trees. We have learned to know a weed when we see it, not, perhaps, that we know much about it, but because it is something out of place, and sooner or later a knowledge of injurious insects will also have to be a regular part of the education of every good gardener. Trees and plants should be examined systematically, and the work of annihilating these pests will not be found difficult when the task is begun in time and pursued intelligently.

Germantown, Pa.

Thomas Meehan.

### Recent Publications.

*The Water Garden*, embracing the construction of ponds, adapting natural streams, planting, hybridizing, seed-saving, propagation, building an aquatic-house, wintering, correct designing and planting of banks and margins, together with cultural directions for all ornamental aquatics. By William Tricker. New York: A. T. De La Mare Printing and Publishing Company, Limited.

Nymphæas may or may not "have existed for all ages," as stated in this attractive book, but there is no question that for the last decade or so they have been much appreciated in gardens, public and private. It is also a fact that no form of horticulture meets with such universal appreciation as the water garden. The largest displays of the showiest or rarest flowers have cold appreciation from a large portion of the public, but there is a charm about a water garden with Nymphæas floating on the placid waters which reflect each passing cloud, and attract so many busy visitors of the bird and insect worlds, that fascinates the most careless observer. Nymphæas being of the easiest possible culture, there is no reason why they should not be grown in the smallest gardens as well as on large estates.

Mr. Tricker has been actively engaged in the growing of aquatic plants during the time when they have most rapidly gained in popularity, and perhaps no one has had a larger experience with Nymphæas of all kinds under cultivation. As will be noticed by the title, this manual is concerned with the practical side of water gardening, the details of which are treated fully. The making of tanks and artificial ponds and the adapting of natural waters to Nymphæa culture are all explained, as is also the handling and propagation of the plants. As to the planting, full details are given with extended lists of varieties, with the lack of perspective usual to such lists. The plant world is full of material in every section. What the intending grower wishes especially to know in starting any new culture is, which are the few best things most probably satisfactory for a beginning. A short list of this kind sharply drawn would be helpful to the increase of water gardens among the readers of the book. Aquatic plants under conditions of ample moisture and warmth grow so rapidly as to require care in selection and planting. As Mr. Tricker says, "overcrowding should be avoided, and everything cannot be represented on the borders of one pond," though we regret to say that some of his well-executed pictures of examples do not bear out his advice, overcrowded and spottily planted borders being sometimes conspicuous, instead of the broad, quiet effects more appropriate in such places. The pictures in the main, however, are suggestive of handsome effects, are well executed, and, like the book, are well printed; and *The Water Garden* is a most useful, suggestive and valuable manual for any one interested in horticulture.

### Notes.

Charles J. Dawson, a son of Mr. Jackson Dawson, for many years head-gardener in the Bussey Institution of Harvard

College, has joined the staff of the Boston Park Department as chief of the Planting Division.

The first carload of California raisins for the season of 1897 was shipped from Fresno in that state on September 3d.

The hops in this state and on the Pacific coast are now all picked. Estimates of the yield in New York place the crop at from fifteen to twenty-five per cent. smaller than that of last year, and it is said the output in the western states will hardly exceed 110,000 bales. These figures indicate a shortage and higher prices than have recently prevailed.

In the Middlesex Fells and Blue Hills reservations near Boston, foxes have of late become so abundant that the question how to lessen their numbers has become a pressing one. They already do much damage in destroying the grouse, quail and other ground birds which inhabit the reservations, while no natural enemies exist to prey upon them in their turn.

Madame Gastellier, the earliest white Chrysanthemum, this season proved to be the first among all colors in this section, and flowers of this variety were sold here on September 18th. During last week there were also in trade flowers of the French variety, Marquis de Montmort, a pleasing pink resembling Viviani Morel, and of the English variety, Lady Fitz Wigram, a white sort.

Mr. E. D. Sturtevant writes us from Los Angeles, California, with reference to *Dendromecon rigidum*, that this plant, in California, is considered one of the finest native shrubs. The flowers are of the brightest pure yellow color, about two inches across and produced for a long period. The foliage is a peculiar grayish green, but the flowers are so beautiful that this may well be overlooked. Unfortunately, it is difficult to transplant, but if successfully moved it grows well in gardens there.

Not only has the Missouri peach crop been remarkably large this year, but all fruits have been abundantly produced in that state, and are of excellent quality. In the six leading counties in the Missouri fruit belt the acreage of bearing Peach-trees is now five thousand acres. Apples, by reason of high color, superior flavor and good shipping qualities, will command extra prices, and every variety of apple has done well. Missouri pears are selling as high as \$4.00 a bushel. Colonel J. R. Rippey, secretary of the State Board of Agriculture, estimates this season's fruit crop to be worth \$25,000,000. More orchards have been planted in Missouri during the past two years than in any other state, and thousands of acres are being set in Grapes.

Lima beans, from New Jersey, now sell at thirty cents a half-peck, and peas and string-beans cost forty cents for the same quantity. The best sugar corn commands fifty cents a dozen. Choice heads of cauliflower, from Long Island, cost twenty-five cents each, eggplants from ten to fifteen cents, and sweet potatoes thirty cents a half-peck. The cooler weather of the past ten days has stimulated the demand for celery, which is coming from near Rochester, in this state, and from Long Island and New Jersey. Cucumbers of uniform and desirable size, from Shelter Island, sell for five cents each; tiny cucumbers from near-by fields, for pickling, bring thirty cents a hundred, and green tomatoes, used for the same purpose, forty cents a half-peck. Small okra costs forty cents a hundred. Tomatoes, Brussels sprouts, kohlrabi, squashes and pumpkins are fairly plentiful, and radishes, carrots, turnips, parsnips, beets, horse-radish, salsify and celeriac are among the root crops now in season.

Crisp Red Callahan apples, from New Jersey, and the soft and more showy Alexanders, from Vermont, are choice table fruits at this time. Siberian crab-apples sell at thirty-five cents, retail, in ten-pound baskets, in New York markets, and large smooth quinces, from near-by gardens, cost \$2.00 a hundred. Although berries are no longer offered, a bewildering variety of fruits is still shown. On one stand in Washington Market are watermelons and muskmelons in plentiful supply at summer prices; large Japanese persimmons, from Florida; immense white Rarripe peaches, from New Jersey; nectarines, from California; fresh figs, from Virginia, in quart boxes, at twenty-five cents; Almeria grapes, from Spain, a portion of the first importation of this season; choice Black Morocco grapes, from California, nearly as large as plums, seven pounds costing sixty cents, besides Flame Tokays and other varieties from California, and Concord, Delaware and Niagara grapes, from Lake Keuka; Seckel, Bartlett and Comice pears; Green Gages, Reine Claude and Damson plums, from this state; Hungarian and Italian prunes, from Idaho, and Silver and Kelsey plums, from California; new grape-fruit from the Bahamas, and oranges from California and Italy. To this partial list of seasonable fruits must be

added chestnuts, the first shipments of which reached this city on September 23d from Ridgely, Maryland, and from cultivated groves in New Jersey. These large and handsome nuts sell for thirty cents a pound. Of course, lemons, bananas and pineapples are offered here, and cocoanuts. Of this latter fruit no fewer than 421,000 were received at this port last week.

A recreation pier, the second now established in this city, was opened to the public on last Saturday, and contracts for building three more are about to be let by the Board of Dock Commissioners. The first pier, at the foot of Third Street, on the East River, has been in use since early in July, and during the summer has been visited each day by from 1,500 to 6,000 persons. The new pier at Twenty-fourth Street extends 720 feet into the East River, and on its two floors can accommodate 14,000 persons. Music is provided every evening of the week, and it is worth going a long way to see the enjoyment of the residents of these crowded sections of the city in their use of these spacious gathering places. Seats are provided along each side. Promenading and singing the choruses to the airs played by a brass band are the main pastimes, while vociferous calls for encores of specially popular songs seem to give no small satisfaction to otherwise orderly boys. To others the water view and the shores outlined with electric street lights and the colored lights on ferryboats and steamships are the greater delight. Dancing proved objectionable after a short trial, in bringing together a disorderly class of people, and is not now permitted. In addition to officers of the Dock Department, matrons, in neat uniform, are in attendance. It is the intention of the Dock Commissioners, if they can get the necessary authority, to inclose the pier in glass and have it properly heated, so that it can be used all the year through instead of during the warm months only. The Park Board now has under consideration a proposition to stock the pier with flowers and plants, and the Board of Education will be asked to provide a course of free lectures for the winter months.

Farmers' Bulletin No. 58, just published by the United States Department of Agriculture, contains information about the Soy Bean, *Glycine hispida*, which is of practical interest to agriculturists. This Bean, of which there are some sixty varieties, is a native of south-eastern Asia, and has been cultivated in Japan and China for many centuries. Professor Georgeson, of the Kansas Agricultural College, made some experiments with the Soy Bean as long ago as 1891 (see GARDEN AND FOREST, vol. v., page 60), and in more recent tests carried on at several of the Experiment Stations its great value as a crop in this country has been clearly proved. In Europe, where successful experiments were made in 1875 and succeeding years, it has as yet failed to become a staple crop. The plant is an erect annual, with branching, hairy stems, trifoliate, more or less hairy leaves, rather inconspicuous pale lilac or violet colored flowers, and broad, two to five seeded pods, covered with stiff reddish hairs. The seeds vary in color from whitish and yellowish to green, brown and black, and in shape from spherical to elliptical and more or less compressed. Under favorable conditions the plant may reach a height of four feet or more. In the extensive series of experiments carried on by Professor Haberlandt in Austro-Hungary, the plants each bore about 200 pods and 450 seeds, and though this is probably considerably above the average it shows this Bean to be remarkably prolific. The flowers are self-pollinated, so that the yield is entirely independent of insects, and this fact renders the Soy Bean free from an important obstacle in the way of the introduction of many legumes into new regions. A crop of seed is insured wherever conditions are such as to allow the plants to make proper vegetative growth and reach maturity. This useful bulletin includes a description of some of the best varieties, the conditions of growth, methods of culture, and chapters on the time for harvesting, amount of forage yielded, the chemical composition of the various parts used for feeding purposes, its digestibility, its value and uses as a soiling crop, a silage crop, a hay crop and as a pasture plant and soil renewer. In the latter connection it is stated that the Soy Bean is highly valued in Japan as a nitrogen gatherer, and is extensively grown there in rotation with cereal crops. When first introduced into the United States this plant did not form root tubercles, owing to the absence of the tubercle organism in the soil, and it has been grown for several years in some localities without the appearance of any tubercles. In other cases they have developed in great abundance after a short time, and an illustration of the roots of a plant grown at the Massachusetts Experiment Station show them produced in great numbers. The purpose of the bulletin is to show the value of the Soy Bean as a forage crop, and an appendix is added by Dr. C. F. Langworthy, explaining its value as food for man.

## Penshurst Place.

PENSHURST PLACE will probably be remembered by American tourists as one of the most homelike of the great show-places of England. The house is placed on level ground in a gently rolling park, where knotty old Oaks stand singly, in immemorial security, on the grassy uplands, and in the hollows where the bracken grows breast-high. Some of these trees are known by the names of distinguished members of the family, or honored guests who have been received there, such as Sir Philip Sidney and Queen Elizabeth. Those who object to the romping character of modern dances may not have noticed a picture in the long gallery in which that illustrious dame is represented as dancing the coranto, a lively Spanish measure much in fashion at the time, in which the lady is lifted at least a foot from the floor by her partner.

The park front of the house is simple (see illustration on page 393), and the park is separated from the home grounds by a low ha-ha, from which the lawn comes up to the gray stone walls, not broken by flaunting beds of gaudily colored foliage plants, but plain and severe, as is suitable for the stern old building.

The pile is long in comparison with its height, as is often the case in old English houses, and bears on its face the marks of having been lived in and added to by many men at various times. The crenelated walls and narrow lancet windows are memorials of the earlier days when the home was only a home when it was possible to defend it, while the larger windows, flanked by Ionic columns, remind one of the work of Inigo Jones and Christopher Wren.

But it is to the garden front of the house, as usual, to which one turns to see the real charm of the place. A wide grass terrace runs very nearly the whole length of the house, and serves as a foreground for one of the most successful attempts at a reproduction of the old English formal garden. About thirty years ago, Lord Delisle and his architect, the late George Devey, designed the garden as it now is, after the manner of those described by Gervase Markham, and that other worthy who disguised his plain English name of Thomas Hill as Didymus Mountaine. From the

broad terrace close under the house one looks down on the flower garden, which is on a lower level and crossed by broad, straight gravel walks which meet at a circular fountain in the middle. A low stone curbing inside the wide grass margin of the paths marks a level still lower, where old-fashioned flowers nod gayly over their little Yew enclosures, which are not too high to hide anything but the earth of the beds. By this arrangement of different levels the flowers are seen from many points of view, so that the stroller has a chance to decide whether he prefers to look down at a mass of brilliant colors on a green lawn or to see and smell the flowers by going among them.

On one side of this sunken garden and at right angles to the house runs a long terrace, called in the language of the writers of old Herbals, a "mount." These mounts were very characteristic of old English gardens and were originally meant to bring a little amusement into the long dull days of the women living in the house. The boundary wall of the garden often overlooked a road, and was sometimes more than ten feet high on the outside. Against this the mount was built, an inside grassy terrace, reached usually by stone steps from the flower garden or a lower terrace. Persons walking on the upper level, which was only a few feet from the top of the wall, could easily see all that went on outside, while remaining safe from intruders. At the end of the mount farthest from the house, and in the angle of the enclosing wall, a garden house was built, which gave shelter from showers and sun, and had the further advantage of yet another outlook.

At Penshurst the mount can be reached either from the house terrace or the garden, but the original purpose of the early designers of mounts has been lost sight of, as it overlooks nothing but the home grounds. It must therefore be considered rather as a quaint addition to the plan, and as a pretty finish to one side of the garden, than as being archæologically correct. The walls of the mount and the house terrace are not the least of the attractions of the sunken garden, covered as they are with Ivy, spaliere fruits and tender shrubs that enjoy the extra protection given by the warmth of the brick.

From the garden straight walks lead to the fish-pond, a piece of water some thirty paces long and twenty wide, surrounded on all four sides by a wide grass verge and a high pleached Yew hedge. This little enclosure carries one back to the middle ages, when such fish-ponds were a necessary part of every priory or large manor house, since their inhabitants contributed largely to the larder on the many fast days ordered by the Church. One would hardly feel surprised, in a place like this, if some day one were to come upon a jolly Friar Tuck, gazing down into the clear waters of the pool and smacking his lips in anticipation of the delicious meal he would have from an especially fat and tender carp. Beyond the quiet pond, long walks, bordered by old Apple and Pear trees and bright with many flowers, open little vistas of the park and woodland beyond. In spring these walks are, perhaps, at their best, when the sun throws chequered patterns through the blossoming trees on the gravel, and the borders are gay with flowering bulbs; but autumn has its own charm in the fruit-laden trees and golden and purple glow of the season's last flowers.

As is so often the case in England, a little village of a few dozen houses huddles under the shadow of the great house, and a gate from the home grounds leads into a quiet street bordered with old cottages and their gardens. No railway disturbs the stillness of this hamlet, which can only be reached by driving from the station some two miles away, or taking a coach which runs from Tunbridge Wells. After this has taken its jingling departure, and when the last belated tourist has gone lingeringly away, the shrill voices of children and the cawing of rooks are the loudest sounds heard in the village.

No more charming excursion than this can be made in a day from London. Penshurst is in Kent, "the garden of England," and surely nowhere does it better deserve the name than at a place where there is a continuous succes-

sion of flowers from the first snowdrops until the last Christmas Rose is past. After a day spent here one goes back to the grimy city, with the lungs full of fresh country air, and the mind of memories of the great house standing in quiet dignity in the old park with its glades where the dun deer lie among the bracken.

EMBOLDENED by the action of Congress in practically revoking Mr. Cleveland's Forest Reservation proclamations and by the attitude of the administration toward the whole subject of our western forests, the lumbermen now controlling a large block of Big Tree forest on the western slope of the Sierra Nevada in California are making a determined effort to obtain from Congress authority to cut the Sequoia timber in the General Grant National Park. This particular portion of the Sierra Reservation includes about fifteen hundred acres, and is covered with an exceptionally fine growth of Sequoias and Sugar Pines, numbering among its vegetable wonders the great tree known as "the General Grant." This scheme of Californian lumbermen to get possession of this body of timber has been incidentally commented on in several of the papers of the Pacific states, but it is likely to remain generally unnoticed or to be forgotten until the country discovers some day that by a skillfully worded amendment to some appropriation bill it has been again robbed of a great possession for the benefit of a few speculators.

It is unnecessary to remind our readers that these Sierra Sequoias are marvels of the vegetable kingdom, unsurpassed in grandeur, and probably the oldest living organisms on the face of the globe. Every individual is a monument which should be sacredly preserved for the benefit of future generations. To cut down one of these trees is a crime, and it should be a matter of national humiliation that a considerable part of the Sequoia forest has been allowed to pass from Government control into the hands of lumbermen. There was no excuse for this; there would be less excuse in allowing those portions of the Sierra forest which have already been reserved for the benefit of the people to be opened to entry. The lumber, even, is not needed by the community, which can be abundantly supplied from the Redwood forests, and no one but a little group of men who expect to make money by this transaction has any interest in the success of this movement.

#### Notes on Cultivated Conifers.—I.

THE climate of the north-eastern portion of the United States is not favorable to the best development of coniferous plants, and only a comparatively small number of them can be satisfactorily grown in this part of the country. It is not always that our winter cold is too severe, for many of these trees flourish in mountain regions where the temperature sinks many degrees below the extremes of even the New England winter, but they cannot bear our dry summers and the drying winds of early spring, which draw moisture from the leaves faster than it can be supplied by the roots often fast frozen in the ground when evaporation is most active. Some beautiful and interesting conifers, however, flourish here, and in the following notes we shall publish the results of our observations on cultivated conifers in the northern and eastern states; and as the members of the Yew family are still popularly regarded as conifers they will be included with them.

In the Yew family (Taxaceæ) eleven genera, and in the Coniferae twenty-seven genera, are now recognized. Of these, however, we need not consider *Pherosphæra*, *Phyllocladus*, *Dacrydium*, *Podocarpus*, *Stachycarpus*, *Saxegothæa* and *Microcachrys*, all Taxids of the southern hemisphere except *Podocarpus*, which comes north of the equator into tropical and subtropical regions of the two hemispheres, as none of them can be grown here except as pot-plants under glass. Of the true conifers we can pass by *Tetra-*

*clinis*, a monotypic north African genus, *Callitris* of Australia and New Caledonia, *Actinostrobus* with its west Australian species, the African *Widdringtonia*, *Fitzroya* of Chili, Patagonia and Tasmania, *Athrotaxis* of Tasmania, *Cunninghamia* with its single south China species, *Agathis* of New Zealand, Australia, the Pacific islands, Brazil and Chili, *Araucaria*, a pretty widely distributed genus of the southern hemisphere, and in Abietineæ *Keteleeria*, another monotypic south China genus. Representatives of many of these genera flourish in the gardens of southern California, and several of them will probably thrive in the south Atlantic and Gulf states, but their cultivation at the north except under glass is hopeless.

The genera of Taxaceæ which are available for our northern gardens are *Ginkgo*, *Cephalotaxus*, *Tumion* and *Taxus*. *Ginkgo* contains now a single species, although during the Tertiary period it was very generally distributed through the colder and temperate parts of the northern hemisphere with numerous species or varieties of which more than sixty have been described by paleobotanists. It is distinguished by the character of its lateral branchlets, which are sometimes elongated and more often short and spur-like, by its fan-shaped, two-lobed, many-ribbed, deciduous, pale green, clustered leaves, diœcious flowers, the males in umbels at the ends of the branches, the females in pairs on the sides of slender stalks. The female flower, which consists of a single naked ovule, becomes in ripening a sort of plum-like fruit, the outer layer of the seed-coat growing succulent, and the inner hard and woody. *Ginkgo* was first made known by the German botanist, *Kœmpfer*, who discovered it in Japan in 1690, and in 1712 published a description, with an excellent figure of the foliage and fruit, in his work on that empire. He had found the tree in temple gardens, and believed that it was Japanese, for early European botanists in Japan had to do most of their botanizing in gardens, and did not realize that many of the most popular Japanese garden plants had been brought from China with the Buddhist religion. Among these introductions was the *Ginkgo*, which grows nowhere indigenously in Japan, although it is now found in most temple gardens, both in China and Japan; and it is possible that this once widely distributed type has only been preserved by cultivation, for if we are not mistaken the *Ginkgo* is nowhere known in a wild state. The unusual power of this tree to bear cold and drought would indicate that it had long inhabited some region with a severe continental climate, and if it exists now at all outside of gardens it is probably in some of the elevated districts of western China or of Mongolia, or on the still unexplored mountains of northern Corea.

In old Japanese temple gardens the *Ginkgo* is frequently one hundred and twenty feet high, with a tall massive trunk six or seven feet in diameter and large drooping limbs sweeping out in wide-spreading graceful curves, and furnished with elongated, leafy lateral branches. Such trees are splendid and impressive objects, especially in autumn, when the leaves which flutter on their long stems become the color of gold. *Ginkgo biloba*, which is also sometimes called *Salisburia*, and by English-speaking people the Maiden-hair Tree, from the resemblance in the shape of its leaves to the pinnæ of the common Maiden-hair Fern, was introduced into the Botanic Garden at Utrecht about 1730. Twenty years later it found its way to England, and in 1784 was introduced into the United States by Mr. William Hamilton, who brought many exotic trees, including the Lombardy Poplar, into this country, planting them in his garden at Woodlawn, near Philadelphia, which, a century ago, contained the richest and most famous collection of plants in America. A male tree flowered in England as early as 1795, but it was nearly twenty years later before female flowers were seen, DeCandolle discovering them in 1814 on a tree at Bourdigny, near Geneva. Scions from this tree grafted on a staminate plant produced in 1835 perfect fruits in the Botanic Garden at Montpellier; and fruit-bearing trees are now comparatively common in Europe; in

the United States they exist in Central Park, New York, in Germantown, Pennsylvania, near Louisville, Kentucky, and probably in many other localities, as the Ginkgo of late years has become a comparatively common ornamental tree in this country.

Stiff and almost grotesque in its early years, with slender, remote, wide-spreading branches and sparse foliage, the Ginkgo does not assume its real character until it is more than a century old. There are few trees whose youth gives so little indication of future splendor; and so little picturesque is the Ginkgo in early life, and so badly does it blend with American surroundings that a great landscape gardener, knowing only young trees, declared that it could have no place in our landscape planting. If, on a bright November day, he had seen the great trees in Kamakura, or in the gardens of Asakura, in Tōkyō, he would certainly have recognized the great possibilities of the Ginkgo for picturesque planting. In the United States the Ginkgo is perfectly hardy as far north as Massachusetts, and thrives as well in the south as it does at the north. There are not, however, yet any very large or fine specimens in this country, although the tree planted nearly a century ago in the garden at Hyde Park, on the Hudson River, has begun to assume mature habit and shows that later generations may hope to see eastern America rival eastern Asia in its Ginkgo trees.

The Ginkgo is very easily raised from seeds, which can now often be purchased from dealers and which retain their vitality for several months, and female plants, which are less common than males, may be obtained by grafting; it is easily transplanted and thrives in deep, rich drained soil, in which it will often increase in height from two to three feet in a year. Nurserymen propagate a variety with leaves which are larger and more deeply divided than normal, and others with slightly pendulous branches and with leaves striped or blotched with yellow, but none of these varieties have much to recommend them.

The yellow flesh of the Ginkgo fruit has a most disagreeable, rancid flavor, but the seed-kernel, which resembles the kernel of the Almond, is sweet and palatable. In China the trees are cultivated for their fruit, which is sold in great quantities in all markets, but in Japan, where the fruit is also gathered and sold, the trees are cultivated for ornament only, and usually only in temple gardens. The wood is bright yellow with a close compact grain, and is capable of receiving a beautiful polish; it is, however, soft and easily broken, and is not considered particularly valuable.

The Ginkgo is certainly one of the most interesting, hardiest and most picturesque trees which have been introduced into the United States, and if a man wants to plant for posterity, for it must not be forgotten that it has taken from five hundred to one thousand years to build up the great Ginkgos of Japanese and Chinese temple gardens, he is reasonably safe in selecting this tree for his purpose.

*Cephalotaxus* is a genus of small trees and shrubs with spirally arranged linear, sharp-pointed dark green leaves twisted on lateral branches into an apparently two-ranked arrangement, dioecious flowers, in stalked axillary heads, the staminate numerous, clustered and capitate, the pistillate in terminal spikes, and drupe-like fruit, similar to that of the Ginkgo. The genus is Asiatic, and its half-dozen still badly defined species are scattered from Japan and northern China to the eastern Himalayas.

The species most frequently seen in our gardens and the only one well known here, *Cephalotaxus drupacea*, is a native of Japan and probably also of northern China. In Japan it is generally scattered through mountain forests, extending northward to central Yezo, where it grows on low hills as an undershrub two or three feet high of the deciduous forest, while on the Hakone Mountains, in Hondo, it becomes a bushy, shapely tree, often twenty-five feet in height. *Cephalotaxus drupacea* is generally hardy in the eastern states, although it frequently suffers in severe winters in New England. Near New York and Philadelphia, where it is more flourishing, it produces fruit abundantly, although in

this country it remains shrubby in habit and is really more interesting as a type of a peculiar genus than it is as an ornamental plant. *Cephalotaxus drupacea* was sent to the Botanic Garden at Lyden by Von Siebold in 1829. He described another species, *Cephalotaxus pedunculata*, a very obscure plant and, perhaps, a garden form of *C. drupacea*, from which it seems to vary chiefly in its longer leaves, or a Chinese species, as there is apparently but one *Cephalotaxus* growing wild in Japan. I have not seen it in our gardens. There is what is believed to be a Japanese fastigiate form of this plant in gardens (var. *fastigiata*) with branches as erect as those of the Irish Yew and very dark green foliage; not hardy in eastern New England, there are good plants of this form near New York and Philadelphia. This plant is often known in gardens as *Podocarpus Korai-anus*, *Taxus Japonica*, *Podocarpus Japonica* and *Cephalotaxus Burgeri*. *Cephalotaxus Fortunei*, a native of northern and central China, is the most beautiful of the cultivated species, with lustrous dark green leaves, pale on the lower surface and three or four inches in length. In Europe this is considered the most desirable of the genus as a garden plant. I do not know it, however, in this country and find no reference to it in American garden literature later than the note nearly thirty years old in Hoopes' *Book of Evergreens*. Like many other north China plants, however, it may be expected to thrive in New England.

The different species of *Cephalotaxus* flourish in deep rich soil and require protection, especially until they are fully established, from the winter sun. C. S. S.

### The Hamburg Exposition.

THE Gartenbau Ausstellung, which is now closing at Hamburg, is the largest and most important effort yet made to show the resources of the horticulturist. It was conceived in a broad and generous spirit, and has been carried to a finish with remarkable energy and sagacity. The time and circumstances have been auspicious for a great exhibition. The Germans are feeling the effects of industrial and commercial expansion, and exhibitions may almost be said to be a craze with them. Hamburg is not only an important horticultural centre, but it is one of the greatest marts of the world. It has an immense fleet of ships reaching many countries. This touch with foreign trade has bred a most conspicuous public spirit, without which a horticultural exposition continuing through five months could not have succeeded. The steamship companies transported exhibitions free and the people of Hamburg subscribed for about 70,000 season tickets to the Ausstellung before it had opened its gates.

The exposition is the outgrowth of a local horticultural society, and is under the direction of committees of prominent Hamburg citizens. The state of Hamburg gave 50,000 marks for premiums, and a guarantee fund was raised by subscription. The receipts of the exposition are derived from gate moneys, rent of space, and concessions to restaurants and tradespeople, and have been sufficient to meet all expenditures, to secure the guarantee fund, and to leave a handsome surplus. This happy condition has been brought about, of course, only by the application of the strictest business methods, and yet the intelligent visitor must be impressed with the liberality of the management and the courtesy and freedom with which it has extended privileges to students and specialists. One is impressed with the fact that while the exposition is a financial success, its motive is, nevertheless, one of public spirit and a desire for the extension of the influence of horticulture.

The site of the exposition is ideal. A public park of about thirty-five acres, splendidly diversified with hill and dale, glade and wood, water and sward, has been made an Eden of color. The effects of herbaceous plants are naturally paramount. Dahlias, Geraniums, Lilies, Gladioli, Azaleas, Rhododendrons, Roses, tree Fuchsias, burning carpet beds, have been some of the most conspicuous

features of the outdoor displays. The greater number of exhibitors have been Germans, but there has been conspicuous coöperation on the part of Belgians, English, Italians, French and other nationalities. America has been represented by but few displays, the most prominent being a very large and fine exhibit of evaporated and prepared fruits from California, and displays of various florist's stock by W. A. Manda. The Americans have certainly lost a distinct opportunity to push their fruit and inventions into European markets. We are looking to Europe to consume our apples and evaporated and canned fruits, and cranberries and other fruits must eventually find an outlet there. The authorities of the exposition urged the Americans to exhibit, and certain Americans endeavored to second their efforts. The apathy of our people in this matter does not speak well for the much-vaunted American thrift. The influx of American apples into Germany last year has thoroughly aroused the people there, and the pomological display at Hamburg represented the abundance and excellence of the fruits of Germany and the Tyrol. The effort was made largely for the purpose of showing that the pomological resources of the Old World are competent to meet the advances of the New World. A thousand barrels of American apples and twenty-five barrels of American cranberries should have been placed in storage in Hamburg in 1896, and the entire course of the exposition should have seen these products on exhibition, and every public function should have seen them supplied to the tables. It would be inexcusable if another great European exhibition should be so completely ignored by the American public.

While the Austellung has been a continuous display from the first of May until the early part of October, there have been several great events, of which the spring exhibition, the autumn exhibition and the pomological display have been chief. The autumn show (Herbst-Austellung), opening late in August and lasting a week, was undoubtedly the grandest display of plants and flowers ever made. Over five hundred exhibitors were represented, and others were turned away because of lack of room. It would be futile to attempt to designate particular exhibits of great merit, but one could not help observing the great Palm exhibit of Winter, of Brodighera, Italy, the choice and rare plants of Sanders, the incomparable Gladioli of Lemoine, and the prodigal display of cut bloom by the Erfurter Handelsgärtner. The Erfurt display received the Laeisz prize of one thousand marks for cut flowers. Prominent features in this display were China Asters, tuberous Begonias, Gladioli, Marigolds, Petunias, Dahlias, Verbenas, Pansies, Zinnias, Celosias, Immortelles and Phloxes.

Dahlias were profuse in the autumn display. Many exhibits were permanent plantations in the grounds, but not all of these were successful. It was apparent—as it is to all Dahlia growers—that soil, season and date of planting exert most powerful influence upon the prolificacy and character of bloom. In the Dahlia plantations the Cactus and single classes were deservedly most popular. Matchless was, perhaps, the leading variety. Three novelties deserve special mention for great individuality and merit: *Perle de la tête d'Or* (an unfortunate name for a white variety) is a most beautiful clear white semi-Cactus French novelty, of good habit and very floriferous, larger than Matchless, and, to my taste, the best introduced novelty displayed at the exposition; Cannell's Gem, a very fine salmon-red Cactus Dahlia; *Stolzer Riese*, a large and broad-rayed single, with very long stems, maroon-claret shading to rose. The hauptpreis of 100 marks was awarded to a collection of cut Dahlias comprising 800 varieties. Two striking novelties exhibited as cut blooms were *Loreley*, a large shell-pink Cactus, and *Hohenzollern*, a very large salmon-buff Cactus. The former is to be introduced in 1898, and the latter in 1899. Cannas were poor, and none of the prizes offered for novelties were awarded. This does not prove that the novelties may not have had distinct merit, but they did not reach expectations in the grounds at Hamburg, a circum-

stance which may have been due to soil, lateness of planting, or other local causes.

The merit of the Austellung lay quite as much in its general plan and effect as in the technical details, and it was this general character which contributed mostly to its wonderful financial success. Thousands of persons who are not interested in horticulture itself must have been touched with the possibilities of the art by visiting the exposition, and must have received an insatiable desire to enjoy the beauties of plants and to introduce them into their own homes.

## Foreign Correspondence.

### London Letter.

**HIBISCUS MANIHOT.**—When treated as a greenhouse plant this old annual species of *Hibiscus* grows to about a yard in height, and is pyramidal shape, clothed with palmately-lobed, dark green, smooth leaves about six inches long, and produces in autumn handsome cup-shaped flowers, five inches in diameter, colored golden-yellow with purple centre. It is a native of China, but has long been naturalized in Bengal, and is commonly cultivated in tropical countries. It was introduced into English gardens nearly two hundred years ago, and has been tried as a summer bedding plant. Recently it has attracted attention through some plants that were sent to a meeting of the Royal Horticultural Society by Mr. Lambert, of Cookham, who sowed the seeds in heat in February and grew the plants outside in summer. They were shown in August, and received an award of merit.

**LILIUM HARRISII.**—The Bermuda Lily is an extremely popular garden plant in this country, large quantities of the bulbs being annually imported from Bermuda, where they are grown in fields for the American and European markets, the annual output being estimated of the value of £20,000. The appearance of a fungoid disease in the fields there has somewhat crippled the industry, still quantities of the bulbs are being received from Bermuda now, full-sized bulbs realizing about fifty shillings a hundred. This bulb is also being grown on a large scale in Natal, from whence an experimental importation was received in London in April last and sold by auction. These were equal in size and quality to the best samples from Bermuda. Two hundred were secured for Kew, and were planted in pots and placed on a cinder bed in the open air. They grew and flowered perfectly in August and September, and proved most valuable for open-air beds and in the conservatory. The Bermuda bulbs flower in April and May.

**MACROZAMIA SPIRALIS.**—Of the numerous species of *Macrozamia* that have been introduced from Australia this is the most useful for ordinary garden purposes, as it grows freely and soon forms an elegant pot-plant. Its dark lustrous green fronds are plumose, and it is almost as graceful as *Cocos Weddelliana*. It is being grown in quantity by one of our leading market growers, who imported seeds of it from Australia, and is now offering it under the name of *Zamia elegans*. All the *Macrozamia*s are ornamental, but they do not all grow freely. *M. spiralis* is the type of a group of species which in stem and foliage closely resemble each other, namely, *M. Fraseri*, *M. Moorei*, *M. corallipes* and *M. Dyeri*. These are all grown in the stoves at Kew. *M. Fraseri* is abundant in Victoria, often occupying large areas, generally where the soil is poor. It sometimes forms a thick trunk six feet high. These stems are easily imported, and seldom fail to grow with ordinary care. A few years ago I bought for sixty shillings two stems, each of which weighed half a hundredweight. These are now handsome specimens in the Palm-house at Kew.

**BOUGAINVILLEA GLABRA SANDERIANA.**—I lately saw some beautiful examples of this plant which had been treated differently from the usual method. Cuttings had been struck and the plants grown on in heat, but the shoots were kept pinched until a shrub a yard high had been formed.

After two years of this treatment the shoots were allowed to grow, but as the plants were in eight-inch pots the growth was not too vigorous. By July handsome irregular bushes had been formed and flower-buds showed in abundance. The plants were then placed outside, where during August and September they were beautiful objects, being heavily laden with flowers several shades deeper in color than those produced under glass. I believe this plant might be grown to flower on a south wall outside in summer.

**ABERIA CAFFRA.**—This, the Kei-apple of south Africa, is again receiving attention, being recommended as a hedge plant for subtropical countries, and its fruit for making jam. It has long been grown for both purposes in south Africa, and I remember seeing about ten years ago a fine hedge fence of it along one side of the Grahamstown Botanic Gardens, thicker and stronger than the stoutest quick hedge and, with its long stout thorns, forming an almost impenetrable barrier to all kinds of animals. It is used

fruit as there is "meat" in an ostrich-egg, is soft, white, sweet and agreeable to the taste. The small black seeds, although numerous, are no detriment, as they are soft and tasteless. There appears to be at least two forms of the plant, one having fruits only about half as large as those produced at Kew. In such states as Mexico and Florida this plant would, no doubt, grow vigorously and fruit freely without much trouble.

**NICOTIANA TOMENTOSA VARIEGATA.**—The type, better known under the name of *Nicotiana colossea*, is one of the handsomest of large-leaved plants for subtropical bedding, for which purpose it is superior to the *Wigandia*. It is now largely grown in English and French gardens, attaining a height of six or eight feet in a season, with leaves a yard or more long and two feet wide. It was introduced from Brazil about ten years ago. I lately saw in the nursery of Monsieur Sallier, in Paris, some plants of a variety which were remarkable for the richness of their variegation. They

Fig. 50.—Gardens of Penshurst Place.—See page 389.

in New Zealand, where, according to the *Waikato Times*, it forms a sturdy, short-jointed grower, an evergreen with thorns six inches long, which are a perfect terror to evil doers, be they beasts or human beings. It fruits freely, and the fruits are of the size of green-gage plums. Professor Macowan, of Cape Town, says of the fruits that although few people like to eat them raw, they make first-rate jam. He recommends a mixture of Kei-apple with tomato as a good jam. This plant fruits freely in the garden of Mr. T. Hanbury, at Mentone, on the Riviera.

**CEREUS TRIANGULARIS.**—An old plant of this night-flowering Cactus has, this year, fruited at Kew, and the fruits are so large and handsome, and moreover so palatable, that cultivators might do worse than turn their attention to this plant as a fruit producer. The fruit is as large as an ostrich-egg and weighs two pounds; it is of a bright rosy crimson when ripe, and the pulp, of which there is as much in each

were more than a yard high, very leafy, the leaves large and their color soft green with a broad, irregular band of creamy white, most of the leaves being more white than green. It comes true from seeds. It also may be propagated from cuttings. It grows with great vigor in the open air, colors without fail, no matter how strong the growth, and it does not burn in bright sunshine.

**BEDDING BEGONIAS.**—The best bedding varieties among the tuberous varieties that I have seen this year are the following: Lafayette, scarlet; Major Hope, pink; Julia Marnier, yellow; Madame E. Turtle, white; Virginia Vanchon, pink and yellow. These are all dwarf and compact, with small leaves, and the flowers stand well up on stout stalks. Their colors are clear and good. Beds of these in the flower garden are as effective as those of the best *Pelargoniums*.

## Entomological.

## A Willow Pest.

THE destructive Willow-borer, *Cryptorhynchus lapathi*, is another insect which has found its way from the Old to the New World, and has now become well established in its new home. The first published notice of its appearance in this country seems to be that given by William Juelich in *Entomologica Americana* for 1887 (vol. iii., page 123), who says in that year he found it infesting a Willow in West Bergen, New Jersey, and that five years previously, in 1882, he had found his first specimen in another locality. In the same season it was found in the northern part of New York City. During many years it has been known to occur in Cambridge, Boston and in their vicinity, and for several years it has proved destructive to almost all species of Willows growing in the Arnold Arboretum. It has been found boring in stems of all the native Willows with the exception of a few mountain or very slender-stemmed species which are too small to afford the borers sufficient sustenance or give them tissue enough in which to make their borings. Of the foreign Willows which become large trees, such species as the White Willow, Crack Willow and Laurel-leaved Willow are more or less attacked, but seem to be less liable to serious damage than the Babylonian Weeping Willow. Besides Willows, this borer has been found to attack all the cultivated Poplars in the Arboretum, particularly when these trees are young, and this season it has been rarely found in small plants of two species of Birch, the Dwarf Birch, *Betula pumila*, and the Red or River Birch, *B. nigra*. In Europe it has been reported as boring in Alders. These instances give a hint of the possible increase in the variety of plants upon which the insect might thrive. So abundant is the pest and so extensive its ravages that it is rarely possible to find a good healthy plant among the shrubby Willows in many localities about Boston. In the shrubby species most of the larvæ are found boring in the lower parts of the stems or nearest the ground, but in those which reach the stature of trees the pests are often found in the higher parts of the stem and the higher limbs.

*Cryptorhynchus lapathi* is a beetle belonging to the great curculio family, which contains thousands of species, and it has been long known in Europe, where it is often mentioned in entomological writings and essays on the culture of Willows. It was described as *Curculio lapathi* by Linnæus, and by later authors placed in the genus *Cryptorhynchus*. Wherever they occur in eastern North America the beetles may be found during July and August on the bark, or sometimes on the foliage of the plants they infest. They are generally not very active in their movements, and when alarmed fold their legs and drop to the ground and remain quiet for a time, in which condition they are not easily seen on account of the fact that their colors and markings harmonize with most soils and débris.

The body varies in different individuals from one-third to three-eighths of an inch, or slightly more, in length. The general color is dull black, with a few very short jet black tufts of bristles or scales upon the wing covers and thorax. Under a magnifying glass the wing covers or elytra are each plainly pitted or indented in ten longitudinal rows, and the thorax is also minutely but irregularly punctured. Scattered over the forward half of the wing covers are numerous minute whitish scales, which are mostly so placed as to form a more or less distinct, broad V-shaped mark, and the tips of the wing covers for about one-third of their length are almost white, with a dense covering of these light-colored scales.

The under side of the abdomen is black or with a few scattered whitish scales upon it, and the sides of the thorax

are densely covered by white scales. The head and proboscis are black, the proboscis usually withdrawn, except when the beetle is active. The legs are black, but marked by numerous white scales disposed either singly or in groups and particularly numerous on the femora, which are usually distinctly whitish on the basal halves of the first pair of legs.

During the summer the eggs are deposited by the beetles in or upon the bark of the Willow or plant attacked; they are hatched soon afterward and the young grubs eat their way into the stem. During the summer and autumn they attain only part of their ultimate growth, remain dormant during winter and continue their boring in spring and reach full size in June or early July. When fully grown the larvæ are between three-eighths and one-half of an inch in length, fleshy, of a dull white color, with brown head and darker mouth parts and an oblong brownish shield on the first segment, back of the head; they are provided with six very short tubercle-like legs on the anterior segments. When fully grown the grubs or borers change to pupæ in their burrows in the wood, and in two or three weeks afterward emerge as beetles. Commonly, larvæ, pupæ and beetles may be found at the same time. Very often the stems of Willows are so riddled by the numerous boring larvæ that there is neither fresh tissue nor sapwood left through which the sap can pass, or old tissue or heart wood to support the stem erect, and death or breaking down follows.

In spring the plants infested are usually indicated by quantities of fine chippings or "sawdust" on the bark or around the base of the stem. Much sap escapes through the holes out of which the sawdust is thrown, and

Fig. 51.—A Willow Pest—*Cryptorhynchus lapathi*.

1. Section of infested wood. 2. Beetle (enlarged). 3. Larva (enlarged).  
4. Pupa, dorsal view (enlarged). 5. Pupa, side view (enlarged).

sap-loving beetles and other insects are often plentiful on the bark or among the débris.

As to a remedy, the cutting out of all infested parts in spring would seem the best, but as any wild Willows, or even plants of other genera, may harbor the pests the idea of extermination cannot be entertained. Where a few choice plants are to be protected heavy soap washings, applied on the bark in July and August, may prevent egg-laying by the beetles. Some parasites have been observed, and these may help to keep this Willow-borer from becoming unduly abundant. At least eight or ten species of parasites are said to affect this *Cryptorhynchus* in Europe. It is recorded as a native of Siberia and other parts of northern Asia as well as Europe.

The above figure has been made by Mr. C. E. Faxon.

Arnold Arboretum, Jamaica Plain, Mass.

### Some Autumn Flowers.

**KNIPHOFIA NELSONI** proves to be a fine addition to the lengthening list of Tritomas. It is distinct in having narrow foliage and small flower-spikes with most intense coloring, the latter a desirable feature in a Red-hot Poker-plant. This variety is the best of the smaller kinds, and specially useful in the front row. Like most of the Kniphofias, it probably would not survive an ordinary winter outside. If it were not for this lack of hardiness these would be much more desirable plants; but in a large collection of plants and bulbs there is such a continuous lifting and replanting through the year that the operation seems less troublesome than when only some odd plant requires this care.

**Aconitum autumnale**, while an old plant, is so neat in finish, both of foliage and flower, that it seems well again to say that it flowers at about two feet in height, with very dark shining leaves and plentiful purple-hooded flowers. It is perfectly hardy, never affected by insects, and may be ranked among the few best autumn-flowering plants. The best of all autumn-flowering plants is the white variety of **Anemone Japonica**, which is not only beautiful, but is in every way desirable. It occasionally disappears in winter, though it is usually reliable.

Asters are such common flowers in the fields and meadows that many growers do not fully appreciate their beauty in gardens at this season. They flourish under cultivation, and though they do not give large flowers the plants become more branched than when struggling for existence, and produce a multitude of attractive blooms. The British give names to the different garden forms, and these added to the numerous species make an endless variety if the cultivator desires a collection. All the plant-nurseries furnish an assortment, seldom properly named, or one can pick up promising kinds in wanderings afield. It must be said, however, that Asters are seed-bearers, and have capacity for taking possession of a garden. The white **Boltonia asteroides** is quite the prettiest of the Aster family for that color, though its flowers are not the largest. Their effect is Aster-like, though the botanist allies them with the *Stenactis*.

Elizabeth, N. J.

J. N. Gerard.

**THE** mild weather is prolonging the season for autumn flowers. **Sedum spectabilis** is just now showy with large umbels of pink flowers. This plant may be increased from cuttings at almost any time, and even flower-stems placed in four-inch pots take root and make nice plants for conservatory decoration. The pretty purple-flowered **Plumbago Larpentæ** is one of the best rock-plants. It makes a healthy-looking mat of foliage and blooms from June onward in a sunny position. **Statice latifolia** is one of the best of the Sea Lavenders, and the sprays of small flowers with persistent blue-colored bracts remain for a long time in perfection; in fact, these plants are scarcely ever out of bloom from midsummer until frost. **Silphium terebinthinaceum**, the *Prairie Dock*, is a majestic plant for the shrubby border or wild garden. The whole plant is glaucous, and the large leaves, with deeply indented margins, are nearly all basal. The stems rise to eight or ten feet in immense cymes with large starry yellow flowers. Tall plants of **Boltonia latisquama** and **B. asteroides** held together by a stout cord look like immense wheat-sheaves; these are covered with small pink and white Aster-like flowers. **Aster amelloides** is one of the best of the dwarf kinds, with large violet-blue flowers. **Salvia Pitcheri**, with long spikes of deep blue, is highly effective just now. The single **Helianthus multiflorus** is worthy of more extended culture. I have always doubted whether this is the type of the double **Helianthus** commonly seen; the single form is hardier. **Geranium sanguineum** attracts general attention; it is never untidy and always in bloom. The white-flowered **Eupatorium ageratoides** and **E. cœlestinum** both suggest the common **Ageratum**. They are among the best of our hardy border plants. Add to these **Pyrethrum uliginosum**, **Anemone Japonica** (pink and white), the *Kniphofias* or *Tritomas* and **Funkia subcordata**, and we have quite a list of flowering plants for an autumn garden.

Wellesley, Mass.

T. D. Hatfield.

### Phloxes (Decussata section).

**THE** perennial varieties of these Phloxes, of which **P. paniculata** appears to be the principal progenitor, are among the most useful and satisfactory of our garden plants. They have justly received considerable attention from hybridizers of late years and rapid strides have been made in their im-

provement, both in the size and substance of the individual flowers as well as in size of truss. Several new shades have been added and the flowers now range through different tints of red, rose, carmine and purple, and even the white sorts are more nearly pure white than the older varieties. Among the white varieties selfs are most abundant. The majority of the other shades have the eye of a brighter or darker shade than the ground color of the flower. A few of the best white varieties are **White Queen**, **Jennie D'Arc**, **White Lady** and **The Perle**. **Marie Stuart** and **Miss Lingard**, two excellent varieties, are both white, with pink eye. In the rose section, **Lothair** and **Puritan** are both good. **Sir E. Landseer** is one of the best representatives of the carmine section, while **Albatross** is probably the best of all the purples. In the brighter or red section, **Aurora Boreale** and **J. H. Slocum** are both good varieties. But their variety is so great that it is needless to enumerate more.

It has been said that Phloxes are plants of the easiest cultivation and do well with very little care. We have always found that they respond quickly to generous treatment, and if provided with a moderately enriched soil, plenty of water when necessary and a good mulching in winter they will more than repay this extra attention by the increased number and larger trusses of flowers. Whether planted in the shrubbery, herbaceous border or in beds by themselves, Phloxes always show to good advantage. They are also useful for cutting, and some of the varieties are highly scented. Sometimes it is complained that their peculiarly sweet odor becomes oppressive in a close room.

The most convenient method of propagation is by division of the crowns, and the scarcer varieties may be propagated by cuttings made from the young shoots. Phloxes are readily propagated from seed, which, however, produce variable results, seedlings seldom coming true to name. Seeds should be sown in the greenhouse in fall, and will in most cases give plants strong enough to produce flowers the following season. We seldom allow them to bloom much the first season, and prefer to cut the flowers off after they have shown their color. They are thus encouraged to make good plants for another season.

Tarrytown, N. Y.

William Scott.

### Chrysanthemums.

**CHRYSANTHEMUMS** which have been growing out-of-doors should be housed by the end of September. They may, of course, remain out until frost is threatened, but nothing is gained by the delay. From the first of October onward a little fire-heat will be found beneficial, as the atmosphere is thus kept dry and mildew prevented. With fire-heat a little air may be left on at the top. While it is necessary to admit an abundance of air, side draughts must be guarded against. All dead or diseased leaves should be carefully picked off, and if, as often happens, thrips attack the lower leaves, a mixture of sulphur and tobacco-water may be used; this serves at once as a fungicide and insecticide. Insects do not like soot, and I have found it efficacious when used with tobacco-water.

Disbudding must be thoroughly done as soon as the buds can be handled, and larger and better-formed flowers will follow. Many small shoots come up through the middle of the plants which will never become tall enough to be on a level with the other branches. In recent years I have pruned these out, and more air and strength are thus afforded to those remaining.

The month succeeding the middle of October is a time full of interest to growers of specimen plants. It is also one of anxiety, for there is yet opportunity to undo a whole season's work by a single blunder. Less and less water will be required as the buds mature, but never so little that the foliage wilts. The roots may be injured by excessive watering, and a serious loss of leaves follows; no treatment will repair this damage.

If the plants are intended for exhibition the date set is too late for some varieties, and these must be held in check. Such plants should be moved to a cooler shady house if possible, otherwise they must be shaded with tissue paper, especially the pink-flowered varieties. Last season I kept a plant of **Joseph H. White** without injury an entire week in a light position in a barn cellar. Chrysanthemums do not bear forcing well, in the ordinary way of increasing the amount of heat. Plants housed and others placed in cold frames show no difference in time of blooming. Plants of tender varieties which have been grown indoors during the summer, may be set out for a few days in September for the purpose of checking the growth and to encourage formation of flower-buds.

Wellesley, Mass.

### Tamarix Chinensis.

BUT few really good autumn-flowering shrubs are hardy and suitable for this climate, and those that are available are not used to the extent which their merits warrant. The beauty of *Tamarix Chinensis* is strikingly displayed in an isolated clump grown where it shows to advantage, and this beautiful plant deserves more general recognition. The whole genus of *Tamarix* is beautiful. There is great similarity in the species, but some flower in early summer, while the season is prolonged until late September by *T. Chinensis*. *Tamarix*-plants are known as being valuable for seaside planting, owing to their ability to endure the saline atmosphere, and they are used to a limited extent in such situations. But their requirements are not by any means fastidious; any soil will suit them, and we have found them perfectly hardy, even young plants surviving severe winters.

It has been objected that these shrubs soon become bare at the base, and this is true of many plants that are not cared for properly. But there is no real objection to *Tamarix*-plants if they are cut back frequently near to the base in spring before they start to grow. Indeed, this is the best possible way to obtain strong shoots with large terminal panicles of the pretty rosy pink flowers; when thus treated the shoots start at once from the base, and often attain to great height by the end of summer. This method applies only to the spring-flowering kinds. Those that flower in early summer, as *T. tetrandra*, should be cut back after the flowering season, in common with all early-flowering shrubs. Too often in small suburban gardens all the shrubby plants are sheared over until they are shaped like more or less symmetrical peg-tops, and all the promise of bloom is shorn off. Inexperienced men will do this sort of shearing as long as the owners are ignorant of the needs of plants, and those who do this kind of pruning are perhaps less to blame than the persons who employ them.

*Tamarix Chinensis* is admitted to be the best of the genus, and is found in some lists as *T. japonica* and also *T. plumosa*; the latter name is suggested by the dense, plume-like habit of growth and panicles of flowers, which are bright pink in the buds and turn to paler pink on expanding.

We have found this genus extremely easy of propagation. It is an easy matter at pruning-time to cut the smaller twiggy growths into lengths of a foot and put them into the open border the greater part of their length. Most of these will grow if the season is favorable. If a greenhouse is available the cuttings may be inserted in pots earlier in spring, and the plants thus started will be much stronger at the end of the first season and should flower the second year.

In the year 1893 Monsieur Lemoine sent out a new species called *Tamarix Kaschgarica*, which he raised from seeds collected in central Asia. This flowers in September and has proved to be a good and distinct plant. It was afterward found to be but a form of *T. hispida*, which has a very wide range geographically. Indeed, the genus has a very wide distribution. *T. Gallica* is found all along the Atlantic shore of France; *T. Indica* is a native of the East Indies; *T. tetrandra* comes from the Crimea; *T. Germanica* is distributed over a great portion of Europe, among the mountains and along the river banks. All of these species are considered hardy in the eastern states, and all are worthy of a place in gardens, especially where saline or alkaline conditions exist, and where it is difficult to make other plants grow.

South Lancaster, Mass.

### Correspondence.

#### Notes from my Wild Flower Garden.

To the Editor of GARDEN AND FOREST:

Sir,—I have been much interested in articles in recent numbers of GARDEN AND FOREST regarding the cultivation of native plants, for my wild-flower plot has afforded me more pleasure than any other collection of plants.

I wish to suggest the Cranberry-tree, *Viburnum Opulus*, for planting in the home grounds. The flat cymes are bordered with larger sterile flowers similar to those of the wild *Hydrangea*, and while less showy than those of its cultivated form, the garden *Snowball*, are truly handsome. I was first impressed with their beauty on seeing a wreath composed wholly of them. The bush is compact and symmetrical in growth, the leaves glossy and untouched by the "curl," which so often distorts those of the *Snowball*, and the deep coral berries are not only ornamental, but their sprightly taste is much relished by some as a substitute for the cranberry. It is said

that old hunters and trappers classify berries "smooth as glass beads" as poisonous; those with a rough point or outward turned surface as harmless; the Poison Ivy and Nightshade are cited as familiar illustrations of the former, the Rose, Whortleberry, etc., of the latter class. The Cranberry-tree furnishes a striking exception to this rule.

The Spikenard is ornamental when in fruit. Its great clusters of berries in early autumn show a rather unusual blending of rich purple clusters resting among others of clear green. Later all are uniformly dyed in the royal colors. Like so many of our native plants with real or reputed medicinal value, this plant is being rapidly exterminated from its native haunts. The ease with which it adapts itself to garden culture will happily prevent its extinction.

The tall Meadow Rue, which dropped its creamy sterile flowers several weeks ago, still retains the fresh green pedicels, giving to the plant a somewhat plumose appearance when seen from a distance. *Viola striata* has bloomed more or less all summer, and now (September 13th) has several blossoms. *Ruellia ciliosa*, which is not indigenous, but transplanted from the western prairies, has proved highly satisfactory, its chief merit being in its constant, rather than profuse, floral display during the midsummer months.

*Coronilla varia*, also a non-resident of this locality, was transplanted from New England a half-decade ago, and finds place in a spot left bare in summer by the dying down of *Hyacinths* and *Tulips*. At first its growth was slow, but finally it entered into a combination with its neighbors, *Lily-of-the-valley* and *Trifolium procumbens*, the latter also a stranger in these parts, and the trio soon had full possession of the ground. Last year all were removed to the base of a neighboring tree, where they grow as they wish. But the subterranean growth of the *Coronilla* quite surprised us, and though we tried to get it out entirely, thrifty plants still appear from time to time on the old site and suggest its vitality when once established. The delicate foliage and dainty blossoms are much admired in their place, but they should not be planted in beds of spring-blooming bulbs.

The wild Yam, *Dioscorea villosa*, and Moonseed, *Menispermum Canadense*, are admirable; both have clean, glossy leaves, the venation and cut of which are in decided contrast. The outline of the Moonseed is decidedly unique, and once seen will be readily recognized. My plant flowers freely, producing only sterile flowers. Its growth is much more rapid and robust than that of the Yam.

Some one has described *Apios tuberosa* as valueless, but while the blossoms are not showy, their form and color are pleasing. The plant grows rapidly and blooms profusely, and many exotics are not nearly so desirable.

Harmonsbury, Penn.

Bessie L. Putnam.

### Meetings of Societies.

#### The American Forestry Association.

THE special autumn meeting of the American Forestry Association, with attendant excursions, was concluded at Nashville, Tennessee, on September 22d, 1897. The plan of combining excursions to special points of interest as joint features of the meeting, proved to be most interesting and valuable, and reflects special credit upon the gentleman in charge of arrangements. It is to be regretted that a larger number of members could not attend, and only fifteen were present for the entire trip. The excursion party met at Washington on the evening of the 16th, en route for Biltmore, North Carolina, the first point of interest. Carriages were waiting and the party was taken in charge by Dr. C. A. Schenck, head-forester of the Biltmore estate. Dr. Schenck thoughtfully supplied each member with a printed catalogue describing all the forest compartments of the estate to be visited, the short history of which could be quickly read as each numbered section was passed. An inspecting tour of the various forestry operations now under way at Biltmore was directed by Dr. Schenck. The large tract of old farm fields, together with mountain, brush and forest land comprising some 13,000 acres, affords the largest opportunity for the application of European forestry principles and practice, with which Dr. Schenck is thoroughly conversant and laboring zealously to apply to American conditions. We cannot pass over the elaborate preparations and pains taken by Dr. Schenck to make the association's visit both profitable and felicitous. Special temporary foot-paths were cut through the brush, weeds and forest growths, by which certain forestry operations could be more easily reached and viewed. Various methods and stages of regeneration were exhibited, including direct planting of seed

and transplanted seedlings consisting chiefly of Oaks, Chestnut, Ashes, Black Cherry, Tulip-poplar, Maples and White Pine. The party was also taken through a number of natural forests in which was explained the evils of the common and the value of the correct method of cutting and taking out useful and ripe timber without the usual damage to young growing stock. In still other plats the practical effect of inter-lucation on natural regeneration was exhibited. Well-stocked forest nurseries and seed-beds conveniently located were visited and the methods of producing young stock for plantations duly explained. At the conclusion of a hasty survey of these interesting operations the party was conducted to the home of Dr. Schenck, which is pleasantly situated on one of the many hills overlooking the broad valleys and distant mountains, and combining in its immediate surroundings and furnishings a forester's ideal home. The visitors were cordially welcomed by Mrs. Schenck and hospitably entertained.

An evening session of the association was held at Battery Park Hotel, the chief feature of which was an address by Dr. Schenck on Forest Finance. The address was confined strictly to the money aspect and profits of forestry operations and was lucidly set forth. The paper was concluded by an elaborate exposition of charts, photographs and sections of trees, illustrating studies in the current and annual growth of important timber-trees in the Biltmore forests. Numerous specimens of lumber and other wood products of the estate were shown as examples of the available timber supplies, together with various tools and appliances used in silviculture. The members were provided with a neatly printed pamphlet containing Dr. Schenck's address in brief form.

In the absence of Mr. M. V. Richards, Land Agent of the Southern Railway, who was to address the meeting, a short paper was read for him by his representative, Mr. James H. Best. The paper was devoted to a general rehearsal of the manifold uses of various classes of woods, with an earnest plea for the preservation of the southern forests. The meeting was concluded by a vote of thanks to Dr. Schenck for his elaborate preparations in behalf of the association meeting.

The morning of the 18th was spent in another visit to Biltmore, in which Dr. Schenck took the party over portions of the estate not seen the previous day, pointing out the agricultural and horticultural operations, also forest road-building, retention of washed lands and other general features.

At midday the party left for Chattanooga, Tennessee, where it took quarters at the famous Lookout Mountain Hotel. The following day was spent in an excursion to the battle-grounds of the vicinity, Missionary Ridge and Chickamauga Park, and a part of Monday in examining the forest growth and other points of interest on Lookout Mountain. Through the courteous attention of Mr. B. L. Goulding, Secretary of the Chattanooga Chamber of Commerce, the pleasure and interest of the visit to Chattanooga were greatly enhanced. Taking train from Chattanooga, the party reached Nashville Monday evening, and spent the following day in sight-seeing and visiting the Exposition grounds.

On Wednesday, September 22d, the principal meeting of the association was called to order at 10.30 o'clock, A. M., in the assembly hall of the Children's Building. Colonel E. C. McDowell, of Nashville, presided and opened the meeting with a few remarks upon the great need of some forest policy for regenerating the rapidly disappearing supply of southern timber, adding the hope that the present meeting of the association would stimulate local interest in so important a movement. In the absence of Major J. W. Thomas, of Nashville, who was to have given an address of welcome on behalf of the city and Exposition, Colonel J. B. Killebrew was introduced as Major Thomas' representative. Colonel Killebrew gave a warm and cordial welcome to the members of the association, touching upon the forest needs and resources of Tennessee. The Vice-President of the association, Mr. J. D. W. French, responded to the address of welcome, and spoke at some length upon the great need of legislative action toward the protection and administration of public and private forests. He cited the private estate of Mr. Vanderbilt as a fitting example of what should be undertaken on a more extensive scale by state and national government. Colonel McDowell then resigned the chair to Mr. French, who proceeded with the programme. Mr. George B. Sudworth next read a paper on the Forest Flora and Conditions of Middle and East Tennessee. The paper was devoted to the general forest, soil and topographical features of the middle and eastern divisions of Tennessee, with a detailed account of the most important timber species of the various regions, and with special reference to their relative abundance, economic character, development and means of natural regeneration.

Colonel J. B. Killebrew followed with a paper on the Forests of Tennessee. Colonel Killebrew dealt with the general features of Tennessee forests, calling attention to the rapid denudation of the past and present, and then gave a survey of the best-timbered counties of the state, with mention of the principal classes of timber cut for lumber and employed for various economic purposes. He reviewed the rise and present rapid increase of wood-working industries of the state, giving statistics of the principal kinds of manufactures, and closed with an earnest expression of the consequent need on the part of the state of some protection against such rapid and wasteful despoliation of the state's most valuable resource. The next paper on the programme was the Effect of Forest Destruction on Water-courses, by Mr. D. W. Baird, of Nashville, in the absence of whom the paper was read by Mr. H. B. Bond, of Nashville. The paper gave a survey of the well-known results of forest denudation at the headwaters of small and large streams, causing a permanent or partial diminution in their supply of water. The afternoon session was called to order by Vice-President D. M. Riordan, of Arizona. The Secretary of the association, Dr. George P. Whittlesey, read a paper on Forests and Rainfall, by Professor H. A. Hazen, of the United States Weather Bureau. Mr. W. W. Ashe, of Raleigh, North Carolina, also read a paper on the Forest Conditions of Iowa, by Professor Thomas H. McBryde, of Iowa. The paper of Mr. George W. Rafter, of Rochester, New York, on Stream-flow in Relation to Forests, was read by title owing to its length and technical character. The remainder of the session was given up to remarks by several members. Mr. D. M. Riordan gave a very lucid and interesting account of the general soil, climatic, topographical and forest conditions of Arizona, with special attention to the San Francisco mountain region. He described the relative position of the various timber and other woody growths from the plateau to the higher elevations, stating that the chief lumber-tree of the San Francisco mountain region is the Bull Pine, or *Pinus ponderosa*. An interesting part of Mr. Riordan's address was the definition of several life zones, and notably the one above 5,500 feet elevation, at which the timber Pine of the region begins to appear in a broad horizontal belt.

Mr. J. W. French again referred to the necessity of general forest legislation, especially in the western states, for the protection of the existing forests, and urged the members of the association to enlist their Congressmen in securing such needed legislation. Mr. D. M. Riordan, in discussing the question, acknowledged the necessity of some stringent laws to control depredators and to protect western forest lands, but called attention to the impossibility, almost absurdity, of a few association members being able to instruct their Congressmen until the communities themselves should reach that understanding of the necessity of forest legislation that they should demand of their representatives the passage of suitable protective measures. At the present time he said the common interest of Arizona communities leads them to oppose all forest protective measures and to look with suspicion or ridicule upon any forest missionary work attempted among them.

Dr. Schenck was called upon for a few remarks and stated briefly that all forestry operations should be viewed only from their money-producing power. Growing forests which would not give a net interest of two to three per cent. on the original and current investment should not be considered up to their proper earning power and should therefore be cut down. He explained the necessity of distinguishing between what must be considered profitable individual and communal or state forest lands, the interests of both ownerships being viewed from different standpoints.

## Notes.

A society entitled Société des Sylviculteurs de France et des Colonies is being formed in France for the purpose of diffusing the knowledge of silviculture and increasing popular interest in this art.

Mr. Harlan P. Kelsey, whose address at present is 1123 Tremont Building, Boston, has regained control of the Highlands Nursery at Kawana, North Carolina, and is now prepared to supply the shrubs and other plants of the southern Alleghanies, which are the specialty of this nursery.

New-crop hickory-nuts, which have been on sale here during the past two weeks, have realized \$2.50 a bushel. Chestnuts, in moderate supply, from the Catskills, in this state, and from as far south as Maryland, have sold for as much as \$12.00 a bushel, but within the past few days have rapidly declined in price.

Strings of peppers have quite transformed the usually unsightly fire-escapes of tenement-houses in the Italian colonies during the past fortnight. The glowing scarlet fruits, in various stages of ripening, are freely festooned, and in the bright autumn sunlight lend a distinctly festive appearance to streets usually given over to dull squalor.

Referring to Mr. Watson's note on three varieties of *Victoria regia*, on page 283 of the current volume of *GARDEN AND FOREST*, Mr. E. D. Sturtevant writes us from Los Angeles, California, that the one alluded to as Dixon's variety is known in American gardens as *Victoria Randii*, and was introduced by Mr. Edward S. Rand, of Para, and named in his honor by Mr. Sturtevant.

The orange crop of California for the coming season, according to conservative estimates based on the present condition, will amount to from 7,000 to 8,000 carloads, as against 5,000 carloads last year. As 300 boxes are required to fill a car this means an increase of from 600,000 to 900,000 boxes of this fruit. Other authorities consider 4,500,000 boxes as not too high an estimate for the amount of this season's output. California oranges from last season are still offered in the eastern states in the choicest collections of fruits; and in rich quality these rival Rodi oranges, the celebrated summer fruit from the Mediterranean. Since the first shipments of new crop oranges from the Pacific coast are expected here during November, the likelihood is strong that California oranges will hereafter be in market throughout the entire year.

*Iris Leichtlini*, figured in a colored plate in *The Garden* of September 18th, is one of the smaller Asiatic *Iris*es of the *Regelæ* group and was first flowered in Baden-Baden in 1879. This *Iris* is one of the most quaintly and daintily marked of these interesting plants. It is perfectly hardy in this latitude without protection, and seems to be longer lived than most of those of the allied *Oncocylus* group. Their successful culture depends on their having a distinct rest in perfectly dry conditions. They are amenable to cultivation in a cool house, and start naturally into growth at this season, coming into flower in March or April. They must have perfect drainage, as they damp off readily. They are also favorites of aphides. If grown out-of-doors they should be planted late, so that their leaves do not appear above ground before hard weather sets in.

The coöperative enterprise known as the Campbell Fruit-growers' Union, in the Santa Clara Valley, California, was recently described in *The Pacific Rural Press* with interesting details. The Union has done much to systematize and improve methods of handling fruit from the time it leaves the orchard until it reaches the market. The shrinkage of each lot is tested, so that the grower shall receive an exact equivalent according to the curing value of his fruit, as well as according to its size and quality. The cost of grading, curing and packing has been greatly reduced, uniformity in the product has been established, and in many ways the growers who have coöperated to furnish a superior grade of dried fruit are securing a fair share of its market value. Twenty-five tons of fruit are bleached here at one time, and seventeen acres are used for drying the fruit in the sun, a double line of steel railway extending to the most distant portions of the tract. The plant has a capacity for curing 7,000 tons of fruit in a season.

Jonathan apples, from Missouri, are now among the choice offerings of this fruit, and other good varieties of apples are Twenty-ounce, Holland, and Fall Pippins, Maiden's Blush, King, Ben Davis, Baldwin and Greening. Selected hand-picked apples of these varieties cost from \$3.00 to \$5.50 a barrel at retail. The receipts of apples in this city last week amounted to less than 21,000 barrels, and in the corresponding week of 1896 reached nearly 47,000 barrels. Many of the peaches now coming from New Jersey are small and generally undesirable, and these sell for fifty to seventy-five cents for a basket holding five half-pecks, while the highest grades command \$1.50. Besides Seckel and Bartlett pears there are now in market Buerre Bosc, Sheldon, Buerre d'Anjou, Buerre Claireau, Swan's Orange and other late sorts. Just after the last huckleberries had disappeared from our markets, and when it seemed certain that the season for summer berries was ended, second-crop strawberries were unexpectedly received by the crate from fields in southern New Jersey. These comparatively limited supplies sold in Washington Market last week at forty-five cents for a quart box. The berries were of medium size, fully ripe and quite showy. Wintergreen berries sell for fifteen cents a quart, and are in considerable favor for eating out of hand. The first Jamaica oranges, well ripened

for so early in the season, reached this port last week in a lot of sixty-one barrels; twenty barrels were at once reshipped to England. Florida oranges were another novelty in this city last week, and sold at high prices. This season's orange crop in that state is estimated at 250,000 boxes. Seventy carloads of California fruits were sold here last week, grapes constituting the bulk of these supplies.

The Smithsonian Institution has undertaken to bring together all available information relating to the medical uses of plants in the United States, and arrangements have been made with the body representing the Pan-American Congress to prepare a report on this subject. A sub-commission for the United States consists of Dr. Valery Havard, United States Army, chairman, Dr. Coville, botanist of the United States Department of Agriculture, Dr. Millspaugh, curator of the Botanical Department of the Field Columbian Museum of Chicago, Dr. Charles Mohr, of Mobile, Dr. W. P. Wilson, director of the Philadelphia Commercial Museums, and Professor Rusby, of the New York College of Pharmacy, who is also chairman of general commission. This committee solicits information concerning the medical plants in the United States from every one in a position to accord it. All packages and correspondence should be addressed to the Smithsonian Institution at Washington and marked on the outside "Medicinal Plants for the United States National Museum." Franks which will carry specimens, when of suitable size, together with descriptions and notes, free of postage through the mails, will be forwarded upon application. Some of the principal subjects which will occupy the attention of the committee are the local names and uses, geographical distribution and degree of abundance of medical plants; whether they are collected for market, whether they are cultivated or have been, with methods of cultivation, and whether the drugs obtained from them are subject to adulteration. In order to assist in the study of the habits, properties and uses of our medical plants the sub-commission undertakes to furnish the names of any plant specimen received, together with all desired information concerning it available. The sub-commission requests that all plants sent shall be represented by at least four specimens.

The exhibition of flowers, plants, fruits, vegetables and cereals in connection with the sixty-sixth fair of the American Institute of the City of New York, began in Madison Square Garden last week. More than 20,000 Dahlia flowers were staged for competition. In the class which required not less than a hundred varieties and six blooms of each kind, above 300 varieties were shown by W. P. Peacock, Atco, New Jersey, and as many by H. F. Burt, Taunton, Massachusetts. These growers were awarded first and second prizes in this class, and also shared honors in other important classes in competition with other exhibitors. There were exhibits of single, double, pompon and cactus Dahlias by professional and amateur growers. The displays of hardy and half-hardy perennials were especially showy. A. Herrington, gardener for H. McK. Twombly, Esq., Madison, New Jersey, showed some new hybrid Tritomas; among these Star of Baden-Baden was specially good, as was Ophir and H. Cannell. One hundred vases of *Gladioli*, each holding from six to twelve immense spikes, comprised one of the brilliant exhibits in this unusually good show. These came from John Lewis Childs, Floral Park, New York. Other flowers shown by the same grower were Tritomas, *Montbretias*, *Phloxes* and *Tuberous Begonias*. The new, deeply fringed double *Hollyhock*, Altoona, was awarded a certificate of merit. Carl Blomberg, gardener for Oakes Ames, Esq., North Easton, Massachusetts, made a large and instructive display of wild flowers and received a first-class certificate for flowers of *Nymphaea cœrulea striata*, never before exhibited, and *N. Eastoniensis*. Besides a large collection of decorative plants, the F. R. Pierson Co., Tarrytown, New York, exhibited a new scarlet *Canna*, Tarrytown, which received a first-class certificate for intense color, free-flowering qualities and general usefulness. Vegetables of extra quality were shown in large variety by J. M. Thorborn & Co., and one of the most popular exhibits in this remarkably interesting show was a collection of chestnuts, walnuts, hickory-nuts and filberts from the Pomona Nurseries, Parry, New Jersey. The exhibition will continue until October 23d, different classes and exhibits being shown each week.

WILLIAM A. STILES, the editor of this journal, died early this morning, after the main portion of this issue had gone to press.

## William A. Stiles.

WILLIAM AUGUSTUS STILES, the editor of this journal since its conception and its general manager for many years, died at the home of his sister in Jersey City on October 6th, after an illness of several months. He was born in Deckertown, in northern New Jersey, near the Pennsylvania line, on the 9th of March, 1837, where his grandfather had removed in 1819, and was the son of Edward A. Stiles and Evelyn Belmont Howell, members of old and respected New Jersey families. His father, who had been educated for the ministry, opened in 1833 a small private school on his farm near Deckertown, which rapidly grew in size and importance, and when he retired from it thirty years later had become the most important institution of learning in northern New Jersey. In this school William A. Stiles, who as a boy was distinguished for intense love of reading and for proficiency in music and mathematics, was fitted for college. He was graduated with honors from Yale in the class of 1859, and the following year became a teacher in his father's school and began the study of law. His health had never been robust, and his sight, injured in boyhood by excessive reading, now became greatly impaired, and he was obliged to give up his legal projects, and in 1864 went across the Isthmus of Panama to San Francisco in the hope of deriving benefit from the sea voyage. This expectation was more than realized, and on arriving in California he was able to accept a position as teacher in English literature and music in a school in Oakland, but soon abandoned teaching to become a member of the corps of engineers engaged in running the line for the Central Pacific Railroad across the Sierra Nevada. The strain upon his eyes in this employment proved too severe, and after a long illness in San Francisco he returned to New York nearly blind. Gradually recovering, he began to study politics and to write political articles for the newspapers. This led to his appointment as a gauger in the New York Custom House, a position which, although never congenial, he continued to fill for several years, leaving it finally to become a member of the editorial staff of the *New York Tribune*, with which he remained closely connected until his death. In

1880 and in 1883 he was defeated as Republican candidate for the State Senate from Sussex County, New Jersey, and for the three years following his second defeat he served the New Jersey Senate as Secretary.

After his return from California Mr. Stiles became interested in plants and their cultivation on the farm and in the garden, and in urban parks, and began to write about them, his contributions to the daily papers on these subjects attracting much attention, and in 1883 he became, in addition to his editorial duties on the *New York Tribune*, the agricultural editor of the *Philadelphia Press*. When the establishment of a weekly journal devoted to gardening and forestry in this country was decided on, Mr. Stiles was selected as the editor. The readers of GARDEN AND FOREST need not be told how he has performed his difficult task. Every week for nearly ten years they have seen the results of his rare editorial judgment, his literary skill, his good taste and unflagging zeal in advancing the knowledge of the special subjects to which GARDEN AND FOREST is devoted. He has been more, however, than a brilliant and successful editor of a technical journal; keen love of nature and sympathy with the cravings of the poor shut within city walls from the sight and enjoyment of the country made him fully understand the value and true meaning of urban parks, and for twenty years, always with that modesty which was one of his strongest characteristics, but with inflexible purpose, he has stood between the parks of this city and the men who at different times and under different pretenses have tried to deface them. His pen saved Central Park from the speedway which threatened to ruin its rural character and destroy its true value. He preserved for the people the charming sylvan glade where it was proposed to place the menagerie which had become distasteful to some of the wealthy residents on Fifth Avenue, and he made it impossible to use Central Park for the Columbian Exposition. It was his forethought and technical knowledge which have modified and delayed the schemes of the men who in their zeal for a botanic garden are willing to deface, unnecessarily, Bronx Park, and could his life have been prolonged this most valuable and beautiful of all the rural possessions of the city might, perhaps, have been spared for the best enjoyment of the public. These are a few of the conspicuous services which he has performed for the parks of this city, but for years hardly a month has passed in which he has not preserved them from some dangerous invasion. An educator in all that relates to parks, reaching the public ear through the press, which had unbounded confidence in his judgment and integrity of purpose, his service to the people has not been merely local; his example has stimulated and his words have instructed, and now in every American community there are who understand the significance of city parks and the difficulties which those who labor to make them most useful have to encounter.

Mr. Stiles was a man of wide and deep sympathies and of unusual intellectual activity in many directions; he loved Nature in all her aspects, delighting in the beauty of trees and flowers in the forest and in the garden, and in their harmonious arrangement; he loved the song of birds, quiet sylvan lanes and sparkling waters. To few men did music mean so much. The love of it came from his mother, a woman of strong intellect and great refinement, from whom, too, came his ready and brilliant wit and keen perceptions. Music was one of the vital and influential forces of his life, and although in later years he was not, except for his own pleasure, a performer, he knew music thoroughly; and his deep insight and instinct for clear analysis made his musical criticisms a source of unceasing pleasure to those who heard them. Other subjects occupied his thoughts. A constant and profound student of the Bible and truly reverential, he was deeply read, too, in English literature and speculative philosophy. A remarkable mathematician, he found mental recreation in solving the most difficult problems; learned

in agricultural chemistry and the breeding of domestic animals, he kept himself abreast of all the latest advances in the science and practice of agriculture. A politician in the best sense and alive to the dignity of citizenship, he enjoyed the game of politics, as he did a horse race, and no man not a professional was better versed in the technicalities of the baseball field and the football gridiron. Shielding himself behind his invincible modesty, this many-sided man long escaped the publicity which he never sought or desired, but eventually the knowledge of his true value spread beyond his personal friends and associates. Two years ago he was made one of the Park Commissioners of this city, a position for which he was in every way admirably equipped, and gradually the public has learned that he was one of the strongest and most valuable men in this community.

His death is a serious loss to the readers of GARDEN AND FOREST, and to every one in the United States interested in landscape-gardening, horticulture and the care and protection of our national and state forests. To this city at this particular time his death is a great misfortune, for it leaves it without its most intelligent and powerful champion in the constantly recurring fight between the people and the would-be spoilers of their parks. Of his life-long devotion to those nearest to him by blood, untiring in its constancy and tenderness, we must not speak here; nor can we trust ourselves to speak of the faithful friend and associate tried by the test of long years of intimate relations, the wise counsellor and the joyous companion. Men who knew William A. Stiles loved him, and to them his memory will be immortal.

#### Notes on Cultivated Conifers.—II.

**T**UMION, or *Torreya* as it is more generally known, is a genus of small trees with elongated lanceolate sharp-pointed alternate leaves spreading in two ranks, and solitary diœcious axillary flowers, the male composed of numerous stamens with filaments dilated above into four anthers connate into a half ring, the female of a single erect ovule surrounded by a fleshy aril which becomes confluent with the woody testa of the seed, the whole forming a plum-like fruit peculiar in the deep folds of the albumen of the seed which resembles that of the Nutmeg. There are now four species known confined to western Florida, California, Japan and northern China, although during the Tertiary period the genus inhabited the Arctic Circle and then spreading southward existed for a long time in Europe, from which it has now entirely disappeared. All the existing species produce handsome close-grained pale yellow durable wood, well adapted for cabinet-making, for which it is used in Japan in considerable quantities.

None of the species of Tumion have taken particularly well to cultivation or shown themselves really desirable garden plants. The Florida Tumion *taxifolium*, which is the type of the genus, is one of the least widely distributed North American trees, being confined to a narrow strip of bluff about forty miles in length along the eastern bank of the Apalachicola River from River Junction to Bristol. This tree can be kept alive in eastern Massachusetts in sheltered, well-shaded positions, and occasionally individuals have survived a number of years in gardens near New York and Philadelphia.

The California species, Tumion *Californicum*, which is really a noble tree, occasionally one hundred feet high, with a trunk four feet in diameter, is not at all hardy in the east, although it is occasionally cultivated in Europe, where it was introduced in 1851 and has produced flowers, although it gives slight promise of acquiring in Old World gardens the beauty which distinguishes it in the forests of northern California.

Tumion *nuciferum*, the Japanese Kaya, is common in the forests of central and southern Hondo and in those of the southern islands as an undershrub or small tree twenty

or thirty feet tall, and rises occasionally to the height of eighty feet, with a trunk four or five feet in diameter, forming a tree unequaled in the massiveness of its appearance and the beauty of its bright reddish bark and dark green, almost black, foliage. Although introduced into Europe more than fifty years ago, the Japanese Tumion, like the other species, has never really flourished in gardens for the reason, perhaps, as has been suggested, that most of the cultivated plants have been raised from cuttings, the seeds of Tumion being exceedingly difficult to transport without the loss of vitality as they soon become rancid. The nature of the climate where it grows, however, in central Japan, and the hardness here of its associates in its native forests give some hope that it may be possible to cultivate successfully this beautiful tree in the eastern states. The kernels of the seeds have a pleasant, resinous flavor, and in Japan are largely used as food; an oil, *kaya-no-abura*, used in cookery, is pressed from them and is an article of some commercial importance.

Very little is known of the Chinese Tumion *grande*, which has not been tried, probably, in our gardens, and which, possibly, will be found identical with the Japanese tree.

*Taxus*, the Yew, is a genus rather widely distributed through the northern hemisphere, with a small number of species all very similar in habit and foliage and nearly identical in flowers and fruit; it is characterized by short linear, alternate, sharp-pointed, dark green leaves disposed in a subspiral and appearing two-ranked on lateral branchlets by the twisting of the short compressed petioles, diœcious or monœcious solitary axillary flowers, the male with from four to eight stamens collected into a globular turbinate head, the female with an erect ovule on a ring-like disk, which enlarging becomes a bright red succulent aril, and nearly encloses the ripe seed. Six species are now known; they are widely distributed through eastern and western North America, Mexico, Europe, northern Africa, and western, central and eastern Asia, the descendants of Yew-trees which have existed since Miocene times.

The best known of all the Yew-trees, *Taxus baccata*, has been cultivated for centuries, and the oldest trees planted by man in Europe are probably Yews, which are believed to live occasionally for a thousand years. *Taxus baccata* is scattered over western and central Europe and the mountains of southern Europe and northern Africa; it reaches southern Scandinavia on the north, and extends through western Asia to the temperate Himalayas, where it is common, ascending to elevations of twelve thousand feet above the sea-level. In India the Yew attains its largest size, sometimes growing to the height of a hundred feet, with a trunk five or six feet in diameter. Usually, however, it is bushy in habit, and trees more than thirty or forty feet in height are not very common. Long before the Yew attracted much attention in modern Europe as a garden plant the wood was in great demand for the manufacture of bows, and for centuries after the Anglo-Saxon conquest Yew-wood bows were the principal weapons of the English. It is still considered the most valuable of the European woods for cabinet-making, and it is manufactured into many small articles of domestic use. In some parts of India the trees are venerated and their wood is burnt as incense, while both the bark and leaves are employed by the native physicians in the treatment of various human diseases.

During the seventeenth century, when the fashion for formal gardens and clipped trees prevailed in Europe, the Yew, which endures better than most trees an annual shortening of the branches, was cut into all sorts of fantastic shapes and was largely planted in hedges, for which purpose it was well suited and is still frequently used. The Yew has always been the favorite ornament for English churchyards, and no English park or garden is considered complete without it.

*Taxus baccata* must have been brought to eastern North America more than a century ago, as there are a number of large individuals in New York, Philadelphia and Balti-

more, for everywhere south of Cape Cod it appears to be perfectly hardy. Further east it suffers from the cold in severe winters, and cannot be considered a desirable tree for general planting in eastern New England, although it can be made to grow indifferently in well-protected situations.

There are found in gardens a number of interesting forms of this tree; of these the most distinct is the so-called Irish or Florence Court Yew, *Taxus baccata fastigiata*, distinguished by its upright branches which form a narrow compact pyramid somewhat broadened at the apex in old age, and large, spirally arranged, very dark green leaves. The plants of this variety are all female, and have been

propagated from one or two individuals found during the last century on the mountains of County Fermanagh and planted in the garden at Florence Court, a seat of the Earl of Enniskillen. This upright-growing Yew, which is, perhaps, the most distinct and desirable of all fastigiate evergreens, appears perfectly hardy about New York and southward, but does not support the climate of eastern New England, where, however, it is occasionally used as a tub-plant for the decoration of terraces and formal gardens. The Devoston Yew, distinct in its long, wide-spreading and somewhat pendulous branches and longer and darker leaves than those of the ordinary form, is a seedling variety which is now often cultivated in Europe and is occasionally met with in the gardens of the eastern states. Another form, *T. baccata adpressa*, with numerous

spreading branches and very short broad leaves, was long supposed to be a Japanese or Chinese plant. Only the female is known, and although now generally supposed to be a seminal variety of *Taxus baccata*, its origin is still doubtful. It is certainly rather hardier than other forms of *Taxus baccata*, and, although it grows here very slowly and remains shrubby, it can be made to live in eastern Massachusetts. Forms of *Taxus baccata* with yellow and with pale or silvery leaves are favorite plants in Europe, and they are occasionally cultivated in the United States; curiously enough, the golden-leaved Yew is much hardier in New England than any of the other forms of this tree with the exception of that last mentioned,

and with a little care it can be grown in sheltered positions in the neighborhood of Boston, although the tips of the branches are often browned during severe winters. Nurserymen have given names to many other seminal varieties of the European Yew, but none of these is particularly distinct or valuable, and none of them can be expected to thrive east of Cape Cod.

Of the North American Yews the very local *Taxus floridana*, which only grows with *Tumion taxifolium* on the banks of the Apalachicola, is practically unknown in gardens, although young plants were introduced two years ago into the Biltmore Arboretum; it is not probable that it would prove hardy at the north, or that it would be sufficiently

distinct as a garden plant to warrant any special culture or care. The Pacific coast Yew, which under favorable conditions becomes a tree eighty feet in height, with a trunk occasionally four feet in diameter, has not been fairly tested yet in the east. It grows not only on the coast as far north as Queen Charlotte Islands, but it spreads eastward to the western slopes of the northern Rocky Mountains in the United States and to the Selkirk Mountains in British Columbia, where the winter cold is much more severe than it is in New England. The snowfall, however, is greater, and small plants are protected all winter and until late in the spring by a deep covering of snow, while in summer the ground, shaded by the dense coniferous forest, never becomes very dry in the situations which this tree selects. The individuals which have failed in the

William A. Stiles.—See page 399.

east have been derived from the coast region, and better success might be obtained with plants from northern Montana, and an attempt to obtain a hardy race of this tree will be made in the Arnold Arboretum.

The third United States Yew, *Taxus canadensis*, is a low shrub, with nearly prostrate, wide-spreading branches, and is a common inhabitant of northern woods, often covering large areas of low moist soil in their dense shade, and is distributed from Newfoundland to Lake Winnipeg, and southward to Virginia and Iowa. This is, of course, a perfectly hardy plant, although it only thrives in moist, shaded soil, and it might be used more frequently than it is to cover the grounds in parks and gardens.

*Taxus cuspidata* inhabits Manchuria, Corea and the Island of Yezo, where it is widely scattered through the forests of deciduous-leaved trees, and where it often rises to the height of fifty feet with a tall, straight stem frequently two feet in diameter. In Japan this Yew is a favorite garden ornament, being one of the plants most generally cut into fanciful shapes, for like the other species it can bear the shears. It was introduced into the eastern United States in 1862 and has proved to be perfectly hardy as far north at least as Boston; it grows rapidly in cultivation and promises to become here a large, long-lived tree and a really important and valuable addition to the list of evergreens which can be successfully cultivated in the northern states. There is a dwarf compact form of this plant with short dark green leaves in cultivation in this country, which probably originated in Japanese gardens; often appearing under the name of *Taxus brevifolia*, it must not be confounded with the true *T. brevifolia* of the Pacific coast.

I have seen in California a Yew with fastigiate, somewhat spreading branches, which had been imported from Japan and which is evidently another garden form of *Taxus cuspidata*. This distinct plant, however, does not appear to have been tried in the eastern states.

All the Yews can be most quickly multiplied by cuttings which strike readily; they all prefer shade and moist deep soil, and they are all slow-growing and long-lived.

All the known plants of the Yew family which succeed or are likely to flourish in the north-eastern United States have now been mentioned, and it will be seen that in this important and widely distributed family only the Ginkgo, the Japanese Yew and the dwarf Yew of the northern states are really valuable and important garden plants in the north-eastern states. C. S. S.

#### *Magnolia glauca*.

"The most part of their underwood are Bayes and such like."—*Hakluyt's Voyages*, vol. ii.

THE Swamp Magnolia, *M. glauca*, with its long coastal range and numerous inland stations between Gloucester, Massachusetts, and southern Florida, varies from a deciduous shrub at its most northern limit to an evergreen tree in the extreme south. Its most common form is that of a shrub from six to twenty feet high, and except for a straggly habit resulting from rapidity of growth, it possesses almost all the points necessary for a perfect plant, having extreme beauty of foliage and flower and delicious fragrance.

The young plants generally develop several shoots that remain almost vertical until the plant is well above the surrounding jungle, when the branches and also the leaves spread laterally. The growth is very rapid, ranging in one season from six inches to five feet, and the flowering branches develop normally three growing points, of which one usually far outgrows the others.

The thick leaves, from three to six inches long, with their shining upper surface reflecting the light and the silver sheen of their lower surface, are the most beautiful to be found among our native plants, for their beauty is of texture and is quite independent of weather, though there are times and seasons when they are unusually striking. These contrasted surfaces attracted the eyes of all the early explorers. The extreme rapidity of growth is understood when we consider the large area of leaf surface and examine the tissues. The upper epidermis is very thick; there is a double and often a triple row of palisade cells, and the lower epidermal cells are extended into two-celled needle-pointed hairs as long as the leaf tissue is deep. Besides this mat of silky fur there is wax on the lower epidermis, so the leaves have immense assimilative and protective powers.

The flowers, the smallest of our native *Magnolia*-blossoms, are of an exquisite ivory-white from two to three inches in diameter; they are borne on short stalks with outspread foliage leaves that fall and flutter about the flowers,

so that, except for their perfume, one might easily pass a blossoming shrub without seeing any of the flowers. The small fruit-cones, about two inches long, have scarlet seeds pendulous from very short filaments.

The inland stations of the Swamp Magnolia have several times been noted in GARDEN AND FOREST (see vol. vii., page 398, vol. viii., page 79), and the most westerly station of which I know, a swamp in the South Mountain at the headwaters of the Conococheague, supplied the sprays photographed by Mr. George Keen, of Harrisburg, and reproduced on page 403 of this issue. The South Mountain Magnolias are now, owing to the invention of the bicycle, in danger of extinction; they may be invisible, but their fragrance betrays them, and the man who collected for me lamented the terrible breakage and waste. Like all true woodsmen, he possessed that knowledge of tree growth and gentleness of touch which enabled him to gather with the least damage to the plant.

The Magnolias of to-day are a mere survival, a remnant, of that once widespread family that, so far as we know, first appeared in America in the Upper Cretaceous. In Tertiary times it was found in central Europe, Greenland, Arctic and mid-continental America, and then was cut off in the Ice Age, everywhere except in south-eastern Asia and south-eastern America. In historic time the written records of Magnolia begin with that first voyage to Virginia in 1584, where on the islands of Pamlico Sound its beauty and fragrance were noted by those keen-eyed old sea-dogs, whose conciseness of description is unequaled. A century later that careful observer and judicious collector, the Rev. John Bannister, took plants of *M. glauca* from Virginia to England, where they were planted in the Episcopal garden at Fulham, by Henry Compton, Bishop of London. Here the Magnolia found an old swamp friend in the fine large tree of Red Maple, taken over some thirty years earlier. About this time the Rev. Cotton Mather, also busy with observations and collections of a less pacific nature, as he was journeying from Salem to Gloucester, paused in his pursuit of witches in order to discover the source of an unknown fragrance, and made known that farthest north colony of *M. glauca* that has since given its name to the town of Magnolia. Exportations of Magnolia to England were continued early in the eighteenth century, for Collinson in 1735 wrote to Bartram "not to send any more cones of your swamp Laurel," but the demand must have increased, for two years later he wrote for more cones, saying "it is a fine plant, and when the wind turns up the silken side of its leaves it has a pretty effect." It is figured and described in Catesby's *Hortus Britanno-Americanus* as *Magnolia lauri-folia* (edition of 1763) and mentioned as one of the American plants with which "England should be enriched." The present specific name, *glauca*, was given by Linnæus, but the older name clung for some time. When Kalm visited Pennsylvania in the middle of the last century the common name was Beaver Tree, owing to the fondness of those animals for the succulent roots.

This native shrub with its long historic record, and growing in at least twelve of the Atlantic states, like all other Magnolias, is popularly supposed to be tropical, though by some curious mental perversion its name is also supposed to be of Indian origin. When we take the ordinary roadsides of the middle states to-day, and see the unsavory weeds growing by the million, there cannot too soon be strenuous efforts made to replace our Jimson and Pig weeds with those older and native growths of Rose and Viburnum, and cover seared brooksides with Rose-Bay and Magnolia, for one marked feature of all the old chroniclers is the unanimity with which they dwell upon the "sweetnesse and goodnesse of our native plants."

Harrisburg, Penn.

M. L. Dock.

The Shad-bush is leafing again by the sunny swamp side. It is like a youthful or poetic thought in old age. I would not fear the winter more than the Shad-bush, which puts forth fresh and tender leaves on its approach.—*Thoreau*.

Fig. 52.—Sprays of *Magnolia glauca*.—See page 48.

## Foreign Correspondence.

## London Letter.

**POLYGONUM LANIGERUM.**—A large round bed filled with this plant is a conspicuous attraction on a lawn at Kew. It has a stout main stem one and a half inches in diameter, with from six to a dozen lateral stems springing from near the base, and the strongest stems are six feet high. Planted in mass it forms a shapely group covered with foliage down to the ground. The leaves are a foot long, petiolate, with a lanceolate blade from three to four inches wide, wavy and elegantly curved; the whole of the leaf is covered with a gray, almost silvery down, to which the plant owes its chief attraction. It is easily raised from seeds, which should be sown in February, and the seedlings may be planted in the open air in June. It is a native of Natal, and for its introduction we are indebted to Dammann & Co., of Naples, in whose catalogue for 1890 it was first offered. It is also figured in the *Gartenflora* in 1890, page 224, fig. 52, where it is described as a herbaceous perennial from six to ten feet high, with flowers in clustered spikes and of a carnation-red color. It is not hardy at Kew.

**VERBASCUM DELPHICUM.**—Of the numerous Mulleins which deserve a place in the garden on account of their large handsome rosettes of leaves, this is one of the handsomest and at the same time one of the least known. It is a native of Greece, whence it has been introduced to Kew, where it is cultivated in a border in the open. The leaves, which form a bold rosette a yard or more in diameter, are broadly obovate, a foot and a half long and a foot in width, and are of a thick flannel-like appearance, gray-green in color, almost silvery white when young. The flowers are borne on a tall, branched, erect spike, and are yellow in color, as are those of most of the species of *Verbascum*. It should be raised from seed sown in spring.

**SATUREIA MONTANA.**—This plant is usually consigned to the kitchen garden, where it is grown among the sweet herbs for seasoning in cookery, and is known as Winter Savory, the whole plant being highly aromatic. It is also worthy of a place in the herbaceous border, or even in the rock garden, as it forms a compact, hardy, suffrutescent evergreen two feet or so high, which in the autumn is covered with bright lilac-purple flowers. It has a prominent place among the rock plants at Kew, where for some time it has attracted general attention. It is a native of the south of France and other parts of Europe, and has been cultivated as a kitchen herb for more than 300 years. It is recommended to be grown near beehives, its fragrant honey being much appreciated. The Summer Savory, *Satureia hortensis*, is a hardy annual with similar properties, but it is not nearly so decorative as *S. montana*.

**BUDDLEIA VARIABILIS**—This is a Chinese species of recent introduction, and from what I have seen of it a promising shrub for the garden. In the nursery of the Jardin des Plantes, Paris, I saw fine examples of it eight feet high and covered with attractive flowers in August this year. It has also flowered against a wall at Kew, and a figure of it will shortly appear in *The Botanical Magazine*. It was described by Hemsley from specimens collected in Ichang, etc., by Dr. Henry, and I believe it was introduced into cultivation by way of the French gardens. It forms a large freely branched shrub with quadrangular branchlets, lanceolate toothed dark green leaves three to twelve inches long, and dense, erect, cymose panicles of bright rosy purple flowers, the individual flowers being small, with a tube half an inch long and a limb quarter of an inch across. It appears to be quite hardy, and the flowering season for it is probably of some weeks' duration.

**CACTUS DAHLIAS.**—An exhibition of Dahlias was a special feature of the last meeting of the Royal Horticultural Society. Sixteen new varieties were awarded certificates, and of these eleven were of the Cactus section. There can be no doubt that for cut-flower purposes the Cactus varieties are preferable to the others, and if they could be made to show their flowers well above the foliage when on the

plant they would be equally superior for garden effect. At present they are not seen to advantage owing to the excessive leaf-growth above the flowers. It was noteworthy that the single-flowered section, so popular a year or two ago, was scarcely represented. In their attempts to breed out the defect in the Cactus Dahlias above referred to growers are losing the quill-like character of the florets which is the most pleasing peculiarity of the pure Cactus sorts. Some of the new varieties which owe their origin to crossing the Cactus and Show sections are defective for this reason. I made a list of the pure Cactus sorts which I thought first-class, both in form and color; they are as follows: Miss A. Jones, crimson; Starfish, crimson; Gloriosa, bright scarlet, by far the most effective Dahlia exhibited, the color being of the most glowing hue and the form large and elegant, the falcate form of the florets being most pronounced; C. Woodbridge, deep maroon; Lady Penzance, sulphur yellow; Mrs. C. Turner, bright amber yellow; Fusilier, terra cotta; Beatrice, bright magenta; Delicata, flesh pink, yellow centre; Keyne's White, the purest white yet raised. With the exception of the last-named the above sorts were exhibited by Messrs. C. Turner & Sons, of Slough, who have held a high position among Dahlia growers and breeders for the past fifty years. I might add as a hint to growers of these plants that the removal of all the top superfluous shoots from the plants strengthens the flowers and permits of there being seen.

**EARLY CHRYSANTHEMUMS.**—Exhibitions in September this year have been remarkable for the collections of flowers of Chrysanthemums shown. Breeders have been paying special attention to this point in recent years and as a consequence we have now numerous large-flowered varieties which bloom in September, that is to say, about two months earlier than the time formerly considered as the season for Chrysanthemums. At an exhibition held in the Aquarium on September 7th I noted a considerable number of Japanese sorts as well as pompons, and at the meeting of the Royal Horticultural Society, held on September 21st, several collections of Chrysanthemum blooms were shown. Some of these were so large and delicate that I suspected they had been forced, but I was assured they had been grown in the open air and had never been under glass. Japanese varieties, measuring six or eight inches across and of the most delicate colors, are, it appears, now available for September effect. Here is a list of the best of those I have seen so far: W. R. Prince, yellow; Milano, maroon; Barbara Forbes, white; Mytchett, white; William Laycock, pale yellow; Mons. Hoste, bluish white, with wide florets; Lady E. Smith, white, broad florets; Lady Kennaway, rosy lilac; Miss E. Silsbury, pure white, large and elegant; Lady Fitzwygram, pure white, recommended as an excellent border variety; Madame M. Masse, rose-pink. These are all Japanese varieties, remarkable for the large size of their flowers compared with the early-flowering varieties hitherto known, and they may be grown either in pots in the open air, to be brought into the conservatory when in flower, or planted out in the herbaceous border for outdoor effect in autumn. They are already attracting the attention of growers of cut flowers for market.

## Chrysanthemums in the Garden.

MY note about autumn flowers in last week's issue of GARDEN AND FOREST does some injustice to Chrysanthemums, in the failure to mention these as the leading autumn-flowering plants. But the last decade has seen the practical disappearance of Chrysanthemums from the open as plants grown by amateurs, and it did not occur to me to note them among the hardy flowers. It is just ten years ago, at an exhibition in Union Square, that the first Chrysanthemums grown for the cut-flower trade were shown in this city, and since that time their cultivation for that purpose has set a pace which an amateur can scarcely follow. That occasion

is specially memorable to me, for I then first came in touch with my friend Mr. Stiles, whose quick sympathies were at once enlisted in an experiment I was making in growing Chrysanthemums in the open under temporary protection, with entire success. This experience was put on record, together with an illustration of the shelter, in GARDEN AND FOREST, vol. i., p. 522. It seems a fitting time to urge on amateurs a more extensive cultivation of these flowers outside, for they are much neglected now in our gardens. However much one may admire the cultural skill of the florists in plumping up massive flowers, these immense blooms leave much to be desired by one who has formed his ideals from campaigning with plants in the border. The florists' chrysanthemum seems to me to bear about the same relation to the naturally grown flower that the conventionally correct man bears to the virile natural being.

There is no more enjoyable garden sight than a mass of glorious Chrysanthemum-flowers swaying on long stems in the crisp October breezes, and in the border under the autumn skies they take on new beauties unknown to flowers on potted plants under glass. The culture and protection are of the simplest. A very light protection will ward off early frost, and by using somewhat heavy cloth, to be rolled up during the day, and a stove for slight warmth at night, the Thanksgiving table may easily be brightened with the rich colors of these out-of-door flowers.

Elizabeth, N. J.

J. N. Gerard.

### Dahlia Notes.

THE Dahlia has been popular for at least a century, and with good reason, for certainly no other garden plant equals it in the profusion of its flowers, the variety of its forms and colors and the length of its time of blooming. At this time it seems to be entering upon a period of higher appreciation than it has yet enjoyed, not only in the two new classes, called Cactus and Decorative (ill-chosen terms), but in the older forms, even the oldest of all, the "show" varieties.

The single-flowered kinds, interest in which has been declining for a few years, are again growing in favor as new combinations of colors, greater delicacy and clearness of tints and fresh developments of form have appeared. Even the foliage of the Dahlia is now taking on an ornamental appearance, sometimes in color, as in the kinds whose young growth is of a purple shade, sometimes in manner of growth, varieties appearing from time to time whose foliage is almost as finely cut as that of a fern.

Another comparatively new point in single Dahlias is that some kinds have a disk which, instead of the yellow color which a few years ago was invariably present, is of a dark color before the expansion of the disk florets. In the varieties Mars and Sirius the disk is red before opening, while in the fine maroon variety, Robin Hood, the disk is also maroon. When the outer ring of the disk of this kind has unfolded its anthers we have a flower all maroon except a ring of bright golden-yellow, a highly-pleasing combination. There is also much variety in the manner of growth of Dahlias; the three varieties just named, as well as some others, instead of branching widely throw all of their flowers upward above the mass of foliage and present a vivid appearance. For some reason all the varieties which have this habit of growth have flowers of some shade of red; there are no pink, white or yellow kinds which carry their blooms in this way.

New "show" and "fancy" varieties continue to appear in the catalogues of the English raisers, and half a guinea continues to be the ordinary price the first year. The difference between these two classes is clear in definition and usually in the flowers themselves. All one-colored flowers and all "tipped" flowers where the tip is darker than the ground color are "show" kinds, while all striped flowers and all tipped ones in which the tip is lighter than the ground are "fancy" varieties. This seems plain enough, but Grand Sultan has a red tip on a yellow ground, yet is classed as a "fancy" because its petals are also striped. Mrs. Saunders is a "fancy," though oftentimes its tips, normally white on a yellow ground, are sometimes light red.

The distinction between these two classes, as far as it depends upon light and dark tips, will probably appear senseless to many, but if it were agreed to call all tipped flowers "fancies" countless disputes would arise at exhibitions, for many seemingly unicolored flowers have the base of the petals white, and a beaten exhibitor would often be tempted to question the verdict of the judges on the ground that his competitor had exhibited tipped flowers. Of course, flowers are as keenly enjoyed by growers who never exhibit as by those who

do; but it is also true that flower exhibitions are refining and educational, and that competition for prizes is a cause of improvement in the specimens exhibited.

The Cactus and Decorative classes are confounded by most dealers as well as by most cultivators. The Massachusetts Horticultural Society made an effort this year to give the prize offered for Cactus Dahlias to true Cactus kinds only. The effort was not fully successful, for the collection which received the first prize had only four Cactus Dahlias out of twelve, the others being of the Decorative class. The American Dahlia Society gave its prizes for Cactus kinds last year entirely to Decorative kinds. If this course continues the true Cactus kinds will be buried under a mass of the other class, some of which, it is true, are exceedingly beautiful, though many are not.

In England the National Dahlia Society has adopted a list of recognized Cactus kinds, to which additions can be made of such kinds as have been judged worthy by a special committee. It would be an excellent plan if the same course were adopted in this country. I should be in favor of adopting the English list and such additions as may be made to it from time to time, providing that American-raised seedlings should also be recognized if they had been certificated as such. When the Cactus class came into existence, in the beautiful representative, Dahlia Juarezi, it became popular, and English growers, in order to share in the profit to be had from them, called all Dahlias Cactus that were not fit for the other classes; the natural result is now seen. I believe that any person who should see that unequaled flower, Gloriosa, would realize the undesirability of including such kinds as Robert Maher, Cannell's Favorite and the like in the same class.

### Plants of Doubtful Hardiness.

A COLLECTION of plants in a well-ordered garden includes many exotics from temperate climates, whose constitution is not sufficiently hardy to withstand our rigorous winters. It is not always the degree of cold from which such plants suffer. The rarity of the atmosphere, especially in the United States, is such that the frequent alternations of freezing and thawing are most trying. The heavy snowfall in New England is favorable rather than otherwise, and the injurious effects of sharp changes of temperature are even more severely felt in localities farther south. As an illustration, Anemone Japonica suffers more in Virginia than it does at Rochester, New York.

The hardiness of a plant cannot always be inferred from the latitude in which it is native or from the fact that it comes from a district from which hardy plants come. There is no rule that all plants of a region are hardy or tender, as the case may be. Our gardens are full of foreign plants which have been introduced from countries where the climate is much milder than ours, and in many other respects different. The common European Box, *Buxus sempervirens*, is quite hardy about Boston, and it is not uncommon to see it used as an edging in old-fashioned gardens. Yet its congeners, the Yew and the Holly, are tender. A knowledge of the natural conditions under which particular plants grow is necessary to their successful cultivation, especially as to their hardiness. *Mathonia Aquifolium* is apt to burn and would be classed as tender, but it is not tender under proper conditions. With a fair amount of moisture and shade, it stands well enough. Seedlings of *Azalea Indica*, from the mountains of Japan, have been brought into the Arnold Arboretum. *Taxus cuspidata* and *T. adpressa*, from Japan, are both perfectly hardy when on their own roots, though doubtfully so when grafted upon the stock of the European *T. baccata*. Curiously, though, the variegated form of *T. baccata* is hardy where the green type perishes. We should be particular when importing these plants, especially standards, as they may be grafted on *T. baccata* stock. The same condition exists with many beautiful *Rhododendrons*, especially in those hybrids where the blood of *R. arboreum* prevails. In this connection it should be noted that all *Rhododendrons* grafted on the *R. Ponticum* stock are doubtfully hardy, and it is seldom that such as have the stock exposed will endure our winters. This is especially the trouble with imported standards.

For the cultivation of Hollies, evergreen *Euonymus* from Japan, *Aucubas*, *Pittosporums*, Yews of the *Taxus baccata* type, some *Cupressus*, *Osmanthus*, *Rhapiolepis Indica*, and all other half-hardy plants of a shrubby character, good cellar or pit room is necessary. A part of a barn cellar will answer, if this is properly set off so that the drainage and gas from manure will not reach the plants. This should be well lighted and thoroughly aired, and if there is a dry subsoil it must be

well watered a few days previous to planting. Two or three waterings during the winter should be sufficient, but extra care must be taken toward spring, when the roots begin to move. If a large number of plants are grown and additional space is required, partly sunken brick or stone pits may be used. These are preferably built on the north side of greenhouses as lean-to structures, or may be made as additions to the barn-cellar. If the roof is flat and there is danger that the skylights will be overweighted with snow, tilted lantern skylights may be built, and this will also provide a good means of ventilation.

### A Thin-skinned Americana Plum.

THE thick, tough and often harsh skin of the native plums is the most serious objection to their edible qualities, especially of those belonging to the Americana species. I have been looking hopefully for a variation in this species that should have the thin and mild skin of the Domestica plums, and now this variation seems to have appeared. A plum has recently been found in northern Minnesota that, with other valuable qualities, has a skin so thin and tender that it can be eaten, when fully ripe, as readily and with as little unpleasantness as the tenderest-skinned European plum. The fruit is very large for a native plum; it ripens early, and while not as rich as some of the finest Americana varieties, is sufficiently tender, juicy and pleasant to rank as first-class.

This plum, which is being introduced by a Minnesota nursery firm under the name Aitkin, appears to belong to the group that was described as *Prunus nigra* by Aiton, and that Professor Waugh proposes to designate as *Prunus Americana*, variety *nigra*.

E. S. Goff.

### Vegetable-garden Notes.

THE vegetable garden presents a somewhat desolate appearance since recent frosts killed all tender vegetables, and comparatively few green crops now remain. We always have all crops removed to the rubbish pile as soon as they are spent, for neatness, and because they are disagreeable to handle if allowed to remain until after sharper frosts. The season now drawing to a close has not been a favorable one for all vegetable crops. There was an abundance of rain, but the temperature in June, July and part of August was much below the normal. There is only about one-third of an average crop of potatoes. Sweet Corn was not up to the average, being poor until the end of August. A great deal of Fodder Corn, grown by farmers in this locality, failed to ripen. A sowing of first-crop Sugar Corn made on July 18th gave us good ears by September 27th; Crosby, sown on July 2d, was ready a week earlier. Tomatoes have not done as well as usual; on light lands the season has suited them fairly well, but in stiff, clayey loam, such as our soil is, the results have been less satisfactory. For an early variety and good cropper, Early Fordhook (Burpee's) has done well; the fruits cracked less than those of any other sort grown by us. Aristocrat, Stone, May's Favorite, Honor Bright and Autocrat all proved reliable main-crop varieties. The past season suited Peas better, perhaps, than any other vegetable, and late sowings of American Wonder and Nott's Excelsior have recently given us nice pickings.

Celery now commands attention, as it is the most important crop remaining in the ground. This season we have been fortunate enough to escape all blight on our plants, although many market-growers complain of the prevalence of rust and leaf blight. As the season advances plants which are being blanched by means of boards will need some protection overhead in the form of a scattering of leaves, hay or dry fern. Winter varieties, such as Boston Market and Kalamazoo, must now be earthed up. Preparatory to this work we mix some air-slacked lime in with the soil about the stems of the plants to keep worms away. Of course, there are various ways of wintering Celery, all of which have something to be said in their favor. We have tried them all and are convinced that the best way to have Celery in good condition throughout the winter, with a sweet nutty flavor, is to avoid storing it in caves, pits and cellars, and to earth it up where it grows and protect it overhead sufficiently to exclude frost, with leaves or seaweed and boards. This plan may involve a little more labor, and market-growers may never adopt it, but for private establishments we believe it to be the best method. Winter Celery should be planted on ground where water never stands; we place ours on light soil and it never fails to winter well.

Root crops, such as Parsnips, Beets, Carrots and Turnips, are stored in sand in an open shed and covered with leaves on

the approach of cold weather. Parsnips should be left where they grow, or, at least, a part of the crop. Their flavor is improved by a few freezings. Those taken out in spring have a better flavor than the stored ones. Parsley may now be planted in a frame; the roots should be shortened and most of the large leaves removed. A few pots in a corner of a greenhouse will furnish a supply while frames are closed up by severe cold and snow. A few roots of Mint placed in boxes and brought into heat later on will also be useful. Lettuces from late sowings out-of-doors are now being transplanted into frames. Some of these will head up by Thanksgiving season, while others will continue the winter supply until they are succeeded by those sown in heat in the new year.

We have just made a sowing of forcing varieties of Tomatoes. These are intended to ripen from the end of February onward. Our earliest sowing now has fruits of a good size, and these will commence to ripen about the first of November. These plants need plenty of liquid-manure and the necessary attention in removing laterals, dead foliage, etc.

With the greater part of the vegetable garden cleared of crops, much may now be done to relieve the pressure of spring work. Beds of Horseradish, Asparagus and Rhubarb may be made now. Manure may be wheeled on vacant land and dug over as time allows, leaving it rough on the surface, so that frost may act on it. To make stiff, retentive soil more workable a dressing of lime rubble, finely screened coal-ashes, sand, road-scrapings or crushed shells may be given. We usually do some trenching in our vegetable garden before the first of December, and always work in plenty of good manure. Ground which has been cropped for half a century is greatly benefited by this treatment, as abundant crops in the succeeding season show.

Taunton, Mass.

W. N. Craig.

### Plant Labels.

A SET of permanent labels which will suit the tastes of all cultivators of plants is not likely to be adopted, but there are several kinds now in use with which little fault can be found. For bearing the names of the larger-growing herbaceous plants and shrubs a strip of half-inch wood three inches long and two inches wide fastened to a bar of iron one-half inch wide, one-eighth inch thick, and of sufficient length to insure stability in the ground, seems to be an almost perfect label. Space is afforded on the surface for the natural order to which the plant belongs, though this is hardly necessary, excepting in public gardens, and for the common and technical names of the plant with its native country. This information can all be written in letters of sufficient size to be clearly legible at a distance of several yards. For the small-growing herbaceous plants and shrubs a good label is in common use in several of the large British botanic gardens. It was, I think, first brought into use by Robert Lindsay, of the Edinburgh Botanic Garden. This consists of a piece of sheet zinc about two and a half inches long, one and three-quarter inches wide, with the corners cut off. For keeping it in good condition a few inches above the surface of the ground a piece of galvanized wire about two feet long is bent double and the looped part is soldered on to the zinc. The prongs thus formed should be about two inches apart when in the ground. Windstorms and freezing and thawing of the soil have no effect in altering their position. The use of acid preparations for writing on the zinc has to a great extent been discarded. Besides their uncertain durability the appearance of the labels when written on with these preparations is decidedly unattractive. An improved method, first used, if I mistake not, by Henry Pfister, the head-gardener of the Executive Mansion, and successfully utilized in Europe since, is to first give the part of the label intended to be written on at least two coats of good white paint; these should be allowed to dry thoroughly. Before writing on this label it should be given a thin coat of black paint over the white, and while the paint is fresh the name should be written with a sharp-pointed stick. The black paint is thus displaced and the white shows through clearly. If the lettering is done properly it will last several seasons. When it becomes the worse for wear it is easily replaced by soaking the labels in a solution of lye to remove the old paint, when the operation of painting and lettering can be reproduced. The lettering is, of course, more legible when done with a camel's-hair brush in black on a white ground, or in white on a black ground. I prefer the latter method, as the entire label is less conspicuous. Labels for potted plants, especially Orchids and fine foliage plants, when made of strips of wood painted white have a glaring look, which detracts from the appearance of the plants. The method already suggested of painting white first, then black, and lettering in white, can

be done successfully either on the ordinary wooden strips, or on strips of zinc made after the pattern of the wooden ones in common use. For large potted plants, especially in public collections, it is advisable to do away with the long strips of wood or zinc, and use instead pieces of zinc three inches long and of sufficient width to hold the names and habitat. These should be fastened to bent wires and fixed in the pots so that they may be read in a horizontal position. Many persons forego learning the name of a plant on account of the inconvenience of trying to read a perpendicular label, and in the case of perpendicular labels they are drawn out of the pot with the prospect of being placed in the wrong pot after they are examined.

Botanic Garden, Washington, D. C.

G. W. Oliver.

## Correspondence.

### The Germination of Conifer-seeds.

To the Editor of GARDEN AND FOREST :

Sir,—A great difference exists in the germination of conifer-seeds from different localities. I have never seen this fact stated in print and give my experience in the hope that others may do likewise. The seeds of all the conifers hardy in the east come up at the same time or nearly so. Norway Spruce, White Spruce, Scotch, Austrian and Mountain Pines, the Colorado conifers, *Picea pungens* and *P. Engelmanni*, Douglas Spruce, *Abies concolor*, and other common conifers can all be uncovered at one time. But few seedlings come up ten days after the first ones appear, while conifer-seeds from a warmer climate are very irregular in germinating. I raised a large quantity in California in 1889 and 1890. The kinds already named were sown in beds adjacent to the more tender kinds. *Pinus Jeffreyi*, *P. ponderosa* and *P. tuberculata* started from two to four weeks before the others came up. *Abies magnifica*, *A. grandis* and *A. amabilis* came very scatteringly; the first of these appeared in April and the last in September, and they required careful attention. The various *Cupressus* varied as much as the *Abies*. Douglas Spruce, *Abies concolor*, and *Pinus ponderosa*, from Colorado, came up much more regularly than the same species from seed collected in California, but the seedlings from California seed made much larger plants at the end of two years. Most of the seed from the Orient acted as those of our native and European species do, being very regular in germinating. The exceptions are *Picea Morinda* and *P. Ajanensis*, but as I had very little seed of the latter and that apparently two or more years old, I may be mistaken in this particular. The seeds of *Sciadopitys verticellata*, *Cedrus Deodara* and *C. Libani* are also irregular in time of germinating. *Cedrus Atlantica* may also be added to the list, but it comes up more evenly than the seeds of other Cedars. The seeds of our native White Pine are the most uneven in germinating of those of the hardy conifers; but although they sometimes come irregularly, this tree can hardly be classed with the species which are irregular in germinating. *Thuja gigantea* and *Libocedrus decurrens* are irregular.

Waukegan, Ill.

T. H. Douglas.

### Fruit-growing in Northern New England.

To the Editor of GARDEN AND FOREST :

Sir,—Thirty years ago, excepting along the borders and on the islands of Lake Champlain, northern New England gave little promise of ever becoming a region for the successful growing of tree fruits on a commercial scale. The winters in the more elevated parts especially were then bitterly severe and long, as now, and the intervening season, though extremely pleasant and healthful, was found to be so short as to prevent many of the choicer fruits from maturing. The most careful and experienced labors to have fruits mature were not successful. A similar condition existed also with our Canadian neighbors, and in our western states, Minnesota and Iowa especially. A few experiments in growing seedlings from the most hardy known kinds were successful, as in the case of Mr. Peter M. Gideon, who in this way produced the Wealthy apple; and there was also some success in the search for wildlings, as in the case of Scott's Winter. But such efforts were too uncertain in their results to be satisfactory. This need of hardy fruits was so marked as to check the growth and prosperity of several states. Strenuous efforts were made about twenty years ago to induce Congress to lend its aid in this direction and some good varieties were thus obtained. The method of distribution through Congressmen was the sending out of scions among their agricultural con-

stituents. But as comparatively few farmers were acquainted with the simple arts of grafting and budding, the general result was not satisfactory. However, some sorts which have proved to be excellent, not only for the north but for the south, were obtained in this way; and these, as they became known (one of them was the very widely grown Yellow Transparent), excited a strong desire for farther study of the tree fruits of northern Europe.

This object was at length effected by private effort, through Professor J. S. Budd, of the Iowa Agricultural College, in association with Mr. Charles Gibb, a wealthy citizen of Montreal, Canada, who was naturally desirous of promoting the interests of his own country in this important work. The labors of these gentlemen were not limited to an investigation of the Apples of northern Germany and Russia; all the tree fruits of those regions were carefully studied through nearly the whole growing season. The results were of great value and importance to the whole range of our northern states, from the Atlantic to the Pacific. I frequently receive requests for scions from northern California, Idaho and Oregon; and already I am in receipt of correspondence showing that the Russian tree fruits are found to have decided value in the states of the Pacific slope.

As for my own experience, I have watched the growth of the trees with daily care, and from year to year I have been more and more impressed and convinced of the great importance of the Russian fruits for a very large portion of our country. I may say that in less than twenty years fruit-growing has become an important rural industry in north-eastern Vermont, and in Maine, and is sure to expand in activity from year to year. Our farmers are rather slow to yield to persuasion in the matter of novelties, but they cannot fail to notice on all sides the increasing numbers of bearing fruit-trees of species and varieties entirely unknown until now. When they see our local markets fully supplied with a class of fruits hitherto seen only in boxes from Boston and New York, it will not be long before the reading and thinking men among them will be taking a hand in such a manifestly pleasant and profitable industry.

Newport, Vt.

T. H. Hoskins.

## Recent Publications.

### *Eighth Annual Report of the Missouri Botanical Garden.*

The eighth report of the Missouri Botanical Garden is before us and contains a financial statement of the President of the Board of Trustees, Professor Trelease's report as the Director, and important scientific papers on the flora of the Azores. From the President's report it appears that the income of the property belonging to the Garden was \$123,962 in 1896, and that the expenditures for the Garden, including maintenance, purchase of plants and seeds, herbarium, library, scientific investigation, etc., including an expenditure of nearly \$5,000 on account of the destructive tornado which visited St. Louis during the summer of 1896, was \$40,108.72, nearly the whole of the remainder of the income having been expended in taxes and in the improvement of real estate belonging to the Garden.

From Professor Trelease's report it appears that at the end of 1895 an inventory of the plants cultivated showed 3,921 named species and varieties other than annuals, and that the number during 1896 had somewhat increased. During the year 10,793 specimens were purchased for the herbarium and 5,674 were received as donations or in exchange. To the library 219 volumes and 702 pamphlets were donated, and 571 volumes and 1,216 pamphlets were added by purchase.

Plans for extending the Garden are being prepared by the Messrs. Olmsted, of Brookline, Massachusetts, it being the purpose of the director to use about one hundred acres of meadow ground adjacent to the Garden for the purpose of displaying a plant synopsis, by which it is proposed to show by living plants, as far as it is practicable to do so, the natural groups of the vegetable kingdom. The practical and theoretical instruction for garden students, which has often been alluded to in these columns, has been continued; and the report shows that this flourishing institution continues to perform a valuable service for botany and horticulture, and that splendid use is being made of Mr. Shaw's noble bequest to his adopted city.

By far the largest part of the report is devoted to a paper

by J. Cardot on the Mosses of the Azores, with eleven plates, and to Professor Trelease's botanical observations on the same group of islands, the result of his visits to them in the summers of 1894 and 1896. Fifty-five plates accompany this paper, which, in addition to a general discussion of the Azorean flora and the agriculture and horticulture of the islands, contains a catalogue of all the indigenous plants known to inhabit them.

### Notes.

A branch of the Yokohama firm of Suguki & Iida, dealers in Japanese plants, bulbs and seeds, has been opened in this city at No. 15 Broadway.

A bronze monument erected in honor of Malpighi, the distinguished Italian botanist of the seventeenth century and the author of the *Anatome Plantarum*, was unveiled at Crevacore, near Bologna, on the 8th of September last.

Fringed Gentians, from woodland borders in northern New Jersey, have been favorites for corsage bouquets during the past few weeks, and these flowers have been so plentiful that bunches containing from fifty to one hundred could be bought for \$1.00.

In the *Orchid Review* for September A. H. Sinee reports the successful results of applying fertilizing salts to Orchids, a number of plants of *Cattleya Trianae* having been experimented on for two years. Equal quantities of nitrate potash and nitrate ammonia were used at the rate of two and a half grains to one gallon of rain-water. Under this treatment the plants made a stronger growth, and produced a greater number of flowers, and these were brighter in color.

A figure of *Lycoris squamigera* in a recent number of the *Botanical Magazine* (t. 7547) reminds us that this noble pink-flowered Chinese *Amaryllis*, first figured in the third volume of this journal (page 176), grows in California with surprising luxuriance. It is freely used in Golden Gate Park, at San Francisco, where it grows without irrigation, increasing rapidly, and produces in September abundant flower-stems three or four feet high. It is more vigorous and beautiful, and apparently much more at home there than in the eastern states, where, however, it is perfectly hardy.

A few specimens of the new rose, Dean Hole, have been on exhibition in the show-window of W. H. Brower & Sons, on Broadway, within the past week. These partly-opened firm buds suggest flowers of large size when fully grown. The Dean Hole rose differs from the cream-tinted President Carnot, which pales under gaslight, in that its rich shell-pink petals are particularly beautiful in artificial light. For this reason it is likely to be in special demand for dinner decorations, and it is expected that the supply will be large enough this winter to provide some of the smaller flowers for this use. The stems are strong and the foliage is luxuriant and pleasing. This rose was first shown two years ago at the dinner given in honor of Dean Hole in this city.

The Department of Agriculture has recently published an important work on the fibres and fibrous substances of all countries, entitled *A Descriptive Catalogue of the Useful Fibre-plants of the World*. The author, Mr. Charles Richards Dodge, special agent in charge of fibre investigations in the department, asks that any information about fibre-plants known to have been employed either commercially or in what may be termed native uses, such as for rough textiles, cordage, fishing nets and lines, basketry, etc., that has been omitted from this work be reported to him. He would also be glad to hear of any native or aboriginal names by which fibre-plants are known in the countries where they grow, which he has not been able to give. He asks, too, for notes on any errors in nomenclature, and for all such information as may enable him to prepare a revised edition of this important work, which is the outcome of a vast amount of patient labor, scientific investigation and technical knowledge.

The horticultural department of the American Institute Fair in this city included many notable exhibits during last week. Stove and greenhouse plants were among the principal attractions. Messrs. Ellwanger & Barry, Rochester, New York, and C. C. Corby, Montclair, New Jersey, had highly creditable exhibits of grapes in large variety. A new quince of large size and regular form won a special prize for Luther Burbank, Santa Rosa, California. In a large collection of semi-tropical fruits was an immense cluster of dates from Riverside, California. Guavas, from Florida, were shown in

large numbers, and their peculiarly sweet fragrance proved almost oppressive even in a large hall. This is said to be the first time this delicate fruit has been successfully shipped and exhibited in the northern states. Pomegranates, from California, were also shown, and the fruits of *Zizyphus vulgaris*, Jujube, from Augusta, Georgia. A collection of 500 species of grasses made by Mr. J. E. Lager in Colombia, South America, was one of the most attractive and interesting features of the exhibition.

The first of this season's Albemarle Pippins, from Virginia, were offered here last week and sold mainly for export at from \$5.00 to \$8.00 a barrel. Owing to dry weather during the past month there is more second-grade fruit in this crop than was expected; this means smaller apples, lower prices, and, according to experience in other years, good keeping qualities. Selected Yellow Globe peaches and the white Stevens Rare-ripes, of choice quality, from the Hudson River district, sell at \$1.50 for a basket holding a peck of the fruit. Large Beurre Bosc pears, from New Jersey, sell for seventy-five cents a dozen. Among other pears of rich quality are Beurre D'Anjou, from California, which lack the rich color sometimes seen in the eastern-grown fruit. The first Easter Beurres, from California, have already arrived; these firm pears, which are at their best in early spring, are now mainly sold for export to the West Indies and Europe. Small muskmelons, from Colorado, the last of this season, cost \$2.50 a dozen. Other specialties in the fancy fruit-stores are handsomely colored mangoes, from Venezuela. These sell at seventy-five cents a dozen, a price warranted by the showy and really palatable specimens, which are altogether the best heretofore seen in this city. Cultivated cob-nuts, or English filberts, have been imported within the past week, from Kent, England. These fresh nuts are sold in their husks and fifty cents a pound is willingly paid by those who esteem their delicate meats. Chestnuts, from cultivated trees in New Jersey, sell for forty cents a quart. Eighteen of these immense nuts weigh a pound and two dozen fill a quart measure. Some of the largest weigh two ounces each.

The Spindle-tree, a familiar shrub in American gardens, was recently described in an interesting article in the *Kew Bulletin of Miscellaneous Information*, which first appeared in *St. James Gazette*. It was stated that the Spindle-tree, *Euonymus Europæus*, is a native European shrub or small tree possessing great ornamental merit, and is too often overlooked by landscape-gardeners. It is deciduous, but its broadly lanceolate leaves of a wavy irregular outline, with minutely serrated edges, turn, before they fall, to a deep rich crimson. The small pale green cross-like blossoms, which open in May, are inconspicuous, but the fruit, when ripe in October, has all the appearance of a flower of brilliant hues. The fruit, indeed, from its color and shape, is the most distinctive as well as most beautiful feature of the tree. Each berry is four-lobed and of a lively rose-pink. When quite ripe the lobes open, disclosing four large seeds covered with a deep orange-colored membrane, the seeds and the husk then presenting a curious but attractive contrast. The wood of the Spindle-tree is exceedingly tough, and the husks and stems of the berries partake of the same character, so that long after the leaves have fallen these remain to enliven the wintry landscape. Birds will not touch them, and with human beings they act as a strong emetic and purgative. The wood is so compact and tough that it is hard to break and almost impossible to splinter. In the days of domestic industries, when every notable maid minded her wheel, it was in request for the making of spindles; hence its common name, by which it is known in Germany and Italy. The wood is also used for making the pointed ends of ox-goads, whence is derived another name of Gatter-tree, or Prick-wood. Chaucer calls the berries gaitre-berries, and in the *Nennes Preestes Tale* recommends them against ague and the humors. In Ireland it is called Peg-wood, because shoemakers use it for pegs for shoes. In France it is also known by the name of Priest's-cap, from the resemblance of the berry in shape to a biretta. Though goads and spindles are gone out of fashion, the wood is still employed in the making of a variety of small wares, such as skewers, toothpicks and fine pins for cleaning watches, and artists are said to prefer the charcoal prepared from the branches to any other, partly from its excellent quality and partly because it is easily effaced. A variety of the common Spindle-tree, bearing berries with white instead of pink husks, is occasionally found; but, although the contrast between the white husks and the orange seeds is curious, the effect is less pleasing than that presented by the berries of the commoner sort.

The Advertising Nuisance.

THE abuse of natural scenery for advertising purposes has long been one of the most abominable of public nuisances. It has now become so flagrant in its atrocities as to be intolerable. There is hardly any section of the country where it can be escaped. In city suburbs, along rural highways, parkways and nearly every line of railway in the land the landscape is marred by the advertising fiend. It is a serious question how this nuisance can be suppressed. Bowlders, ledges, cliffs, fences and buildings are painted over with hideous letterings, and quiet meadows are defaced by gigantic signboards. Journeys, whose chief interest used to consist in the enjoyment of scenery from car windows, are converted into nightmare pilgrimages. Scenery in travel has thus lost a great part of its charm; the lover of natural beauty can only be secure in his enjoyment by selecting some spot, if he can, where such things do not intrude, and resolutely staying there.

There are laws on the statute books of several states prohibiting the use of natural scenery for advertising purposes. Where there chances to be local interest in the subject sufficient to see that these laws are enforced they serve their purpose to a limited extent. But, as a rule, there is nobody whose duty it is to enforce them. Protests are loud enough, and they indicate a widespread public sentiment against the nuisance; but there is seldom any one who will take the trouble to bring complaint against the offenders. In a few places rural improvement societies have taken the matter in hand, and conditions are bettered correspondingly; in others the local officials have been required by public sentiment to enforce the law, with gratifying results. The main trouble is, however, that the scope of these laws is not sufficiently broad to meet the extensions of the evil that mark the more recent methods of the landscape-advertiser. Nevertheless, encouraging indications of changes for the better are to be noted in certain enactments and in efforts to secure such legislation as will effectively deal with the trouble. Some of these are mentioned in the latest report of the Massachusetts Trustees of Public Reservations. The standing committee of the trustees has observed during the past year several marked signs of general

disgust at the doings of advertisers: "For example, the state of New York has passed an act granting powers to the Park Department of the city of New York which will enable them to control all advertising within 350 feet of any public park or parkway. The Boston Metropolitan Park Commission proposes to restrict its reservations by making the acceptance of a restriction forbidding advertising a condition precedent to the use of the park border-roads by adjacent land-owners. The Pennsylvania Railroad Company, by instituting cash prizes for the best-appearing properties along its lines, is competing with the advertisers with excellent results. The English society for checking the abuses of advertising is pressing a bill in Parliament, which, if enacted, will institute local option in this matter by empowering such communities as accept the provisions of the act to frame and enforce strict by-laws regulating the practice of public advertising."

It would be interesting to see how far the common law may protect the public in this matter. It is an axiom that moral right should be legal right as well. The law should embody the sentiment of the community in this respect, and it is probable that a powerful public sentiment would soon convert moral right into legal right. The modern extensions of the scope of the common law in relation to public nuisances indicate that the protection of the public in this regard is properly a function of that law. In equity no man has a moral right to use his property in any manner detrimental to public welfare. The law relating to public nuisances is based on this principle. Modern public sentiment now regards as public nuisances various actions which were once held to be well within the limit of individual rights, and the common law is interpreted accordingly. It has long been recognized that no person may be permitted to pollute the air and the water, for they are thus made detrimental to public health. Later the pollution of the ground was placed under the ban for the same reason. Later still it has been recognized that the nostrils and the ears of the community are entitled to protection in the same way. Foul smells and loud and discordant noises have therefore been adjudged public nuisances under the common law, and there is a goodly line of decisions to that effect.

Modern science demonstrates that the health is powerfully affected by the condition of the nervous system; all diseases are aggravated by undue drafts upon the nervous energy, or by abnormal excitement of the nerves. Health is protected by defending the ears against assaults that injure the nerves, and we have seen that the common law has been made to cover the general welfare in this regard. There only remains, therefore, one other great avenue of sense to be guarded. It seems clear that offenses against the vision may with equal justice be brought under the scope of the common law and thus be adjudged public nuisances. Irritations of the eye, caused by hideous objects, offend the senses in the same manner that hideous noises offend the ear and foul smells offend the nostrils. The nerves suffer in the one case as they do in the others, and public health is injured accordingly. The public has a vested right in the landscape, whether the land be a public or private possession, and no man should be permitted to transgress that right wantonly. A long line of precedents exists to indicate that there is no one sense which arbitrarily is not entitled to the protection enjoyed by the other senses.

In the case of offensive advertising in the neighborhood of a parkway, it is evident that such advertising is displayed to attract the attention of the people that frequent a public pleasure-ground. The action of the public in establishing a place for common recreation therefore gives opportunity for certain private individuals to make a profit at public expense and to the detriment of the public in its enjoyment of the recreative facilities thus created. Without the public pleasure-ground the adjacent lands would be worthless for advertising purposes. The public therefore has just cause to seek redress for the injury occasioned in diminishing the

value of its recreation-grounds for the purposes for which they were intended.

Railway corporations suffer in the same way. Many a railway has gone to very heavy expense in making known to the traveling public the scenic attractions of the country along its line. The railway has, perhaps, been built largely with the purpose of developing and making accessible these attractions. The fact that the public has been drawn to patronize such a route of travel gives value to the neighboring lands, and when such lands are used by the persons owning or hiring them in a way which is a detriment to the parties that give them value—both the railway company and the traveling public—the company is clearly injured in its property rights as well as the public in its common rights, and they therefore have just cause to seek redress for damages inflicted.

The case of a public road is similar. The facilities created by the public for its own convenience are what has given the value to abutting property. This being used for advertising purposes to the public harm, the public has cause to seek redress. The park authorities, the railway company, the authorities representing the public in its ownership of the highway; these, as well as any individuals, should be sustained in a case in equity against offensive advertising as a common nuisance.

In Massachusetts the public park laws authorize park commissions to take, by right of eminent domain, not only lands, but rights in lands. It is clearly within their jurisdiction, therefore, to take such easements in lands about public parks and parkways as will forbid their use for offensive advertising purposes. The damage sustained by land-owners in such takings could not be material, for whatever profit they might gain by putting their property to such use would be enormously offset by the damage inflicted upon public rights through such use. This should be an effective weapon, in addition to the restrictions already alluded to as imposed by the Boston Metropolitan Park Commission.

It has been suggested that persons offended by obnoxious advertising unite in boycotting the wares thus advertised. Unfortunately there is too large a part of the public indifferent to such considerations, and advertisers would hardly be induced to reform their ways for fear of the consequences. A concern, however, could not advertise itself to better advantage than by announcing in the public prints, "The advertisements of these goods are not used for defacing natural scenery!" It would constitute a badge of respectability.

#### Notes on Cultivated Conifers.—III.

THE first of the genera of Coniferæ (Tribe Cupressineæ) which we shall consider in these notes, *Juniperus*, is well characterized by its subulate or scale-like leaves, diœcious, axillary or terminal flowers, the staminate with numerous stamens arranged on a central axis, the pistillate of many scales, each bearing one or two erect ovules and becoming thick and succulent and forming a berry-like strobile at maturity. Of the three sections in which botanists have grouped the species of *Juniperus* only *Oxycedrus* and *Sabina* need interest us here, as the single species of *Caryocedrus*, *Juniperus drupacea*, distinguished by its capitate staminate flowers and united seeds, will not probably prove hardy in our region, although Mr. Hoopes states in his *Book of Evergreens* that it succeeds in the neighborhood of Philadelphia. It is a small bushy tree, rarely thirty feet in height and rather widely scattered from Greece to northern Syria on mountain slopes, between two thousand and five thousand feet above the sea-level, sometimes forming open forests or often mingled with Oaks and Pines. The blue, fleshy, succulent berries of this tree, which are often nearly an inch in diameter, are said to be edible. In the other sections of *Juniperus*, where we are to find garden plants for the north, there are about thirty-five species, widely and generally distributed through the sub-

arctic and temperate regions of the northern hemisphere, being, however, most abundant in countries of small rainfall. They are very common in the arid south-western part of the United States and in northern Mexico, and in the countries bordering the Mediterranean, the largest number of species being segregated in these two regions. Junipers are scattered also from the Arctic Circle to the Bermuda and West Indian Islands, the Atlantic Islands, east tropical Africa, the Himalayas, and over eastern Asia, although it is only in arid or comparatively arid regions that they are numerous enough to be really conspicuous features of vegetation.

Junipers produce durable fragrant wood much used for posts and in the manufacture of many small articles, and the bark of many of the species contains sufficient tannic acid to make it valuable as a tanning material. In the fruit there is an essential aromatic oil used since ancient times in medicine; to Juniper fruit gin owes its peculiar flavor, and from the young leaves and branches of an Old World species savin oil is distilled.

Of the section *Oxycedrus* with seven or eight species, distinguished by axillary flowers, and ternate linear acicular leaves joined only at the base and white-glaucous on the upper surface, the most generally known species, *Juniperus communis*, is more widely distributed than any other tree or shrub of the northern hemisphere and in many forms has been cultivated for centuries in northern gardens.

In America this plant is distributed from the Arctic Circle on the Atlantic coast to the hills of Pennsylvania, to northern Nebraska, along the Rocky Mountains to western Texas, New Mexico and northern Arizona, and from Alaska to northern California; in Europe it is common all over the northern and central parts of the continent, and occurs on the mountains of the Mediterranean basin; it is spread over northern, central and eastern Asia, extending southward to the north-eastern Himalayas and by the way of the Kurile Islands and Kamtchatka nearly completes the earth's circle.

In the north-eastern states *Juniperus communis* is a rather common inhabitant of stony hillsides, where it makes broad masses of stout stems three or four feet high, spreading near the base and then ascending; at high elevations in the western part of the continent and far northward the stems are still more prostrate, forming close mats, and the leaves are often short and broad (var. *Sibirica*); and it is only on the bold and broken summits of conglomerate sandstone and limestone hills in one district of southern Illinois that this Juniper attains the habit and size of a small tree, although in central Europe it is often tree-like in its habit of growth.

The common hillside form of *Juniperus communis* is useful in forming low masses of evergreen foliage, or, grown singly, it will soon make a handsome specimen, which in time will become several yards in diameter. It is, of course, perfectly hardy, and small plants can generally be found in old New England hill pastures and easily transplanted into the garden. A variety of this plant with bright yellow leaves and branches, which was first propagated and distributed a few years ago by the late Robert Douglas, of Waukegan, Illinois, is now frequently planted by the admirers of such abnormally colored plants.

Of the European forms of this species the most distinct is the Swedish Juniper (var. *Suecica*), a plant with erect branches forming a narrow, compact pyramidal head, and occasionally eighteen or twenty feet high. This is one of the few strictly pyramidal conifers which are really hardy in New England, and it can be safely used here in formal gardens or wherever it is desirable to produce the peculiar effects which can only be obtained with pyramidal plants. Another fastigate form of the common Juniper, the so-called Irish Juniper (var. *Hibernica*), with rigid erect branches clothed with short deep green leaves, is a favorite European garden plant; but in this country it is not very hardy, even in the neighborhood of Philadelphia.

The Polish Juniper (var. *Cracovica*) is a robust and hardy plant with abundant foliage and pendulous terminal

branchlets. More distinct than this last is an erect form of general pyramidal outline with delicate drooping branches and narrow leaves, usually known in gardens as *Juniperus oblongo-pendula*. This handsome plant is perfectly hardy in the neighborhood of Boston; it grows, however, very slowly, and in a quarter of a century, even in good soil, will hardly attain a height of six feet. For covering rock-work or for other positions where it is desirable to use an evergreen only a few inches high, the northern and alpine form of the common Juniper (var. *Sibirica*), with its wide-spreading stems pressed close to the ground, is an excellent plant, retaining its habit in cultivation and soon extending itself over a large area.

The other European species of the section *Oxycedrus*, which are small and not very important plants, are not hardy here at the north, but the Japanese *Juniperus rigida* can be grown in our gardens. Of rather more open habit, it is of the *Juniperus communis* type, although the branches are more slender and the leaves narrower and more elongated. On the Island of Hondo, where, although widely distributed at low elevations, it grows only on sandy barrens or dry sterile gravels, it is occasionally arborescent and twenty feet tall, but much more frequently remains low, forming a wide-spreading bush. This is the Juniper which the Japanese most frequently cultivate and which is often seen of large size and venerable appearance in their temple gardens.

Another Japanese species which may be expected to thrive in our gardens, *Juniperus conferta*, is a seashore plant which covers exposed sand-dunes with its long, stout, prostrate branches, and is distinguished in the dark green of its stout elongated leaves and in the size of its fruits, which are much larger than those of other Junipers of this section. This species was discovered by Charles Wright, the botanist of the Wilkes' Expedition, on the shores of Hakodate Bay, opposite the city of that name, on the Island of Yezo, where we have seen it growing in great abundance. In 1892 it was found by Mr. Veitch near Honjo, on the west coast of Hondo. C. S. S.

#### The Corsican Pine at Home.

THE prospect held out to us of a visit to the Corsican Pine forests was a tempting one. We remembered a reply made by a *garde général* in Corsica to the directors of the exhibition of 1867: "Impossible to send you, as you ask, sections of the trunks of our tallest Laricios; our longest saws are shorter than the diameters of our great trees." Then there were the more recent impressions got from the accounts of travelers in Corsica, and eloquent descriptions, concluding with the inevitable advice to "make haste if we wished to see really ancient trees and forests in their natural state." An excursion to Corsica was planned in the spring of 1897, but for various reasons the original band was reduced to four. These found their way to Ajaccio under the guidance of a Corsican, by adoption if not by birth, Monsieur Doumet-Adanson, who was so suddenly stricken by death after our return to France. In Ajaccio we were cordially welcomed by the Conservator of Forests, who gave us some valuable information on the present condition of the Pine forests. Monsieur Mabaret also insisted upon planning out an itinerary for us, which enabled us to see the best examples of Laricio in the limited time allowed to us.

The majority of the Corsican Pine forests are very easily approached to-day, the department of Bridges and Highways having constructed some marvellous roads, but there are other forests situated in remote valleys which are still only to be reached by way of mule-paths and goat-tracks. In these the largest trees, even when decayed, are still left standing, as their removal cannot be economically effected; also isolated trees situated in the rockiest and least accessible places remain intact for the same reason. Our party, which included one person already advanced in age and in delicate health, was not equipped for journeying over

mule-paths and scaling goat-tracks; the finest forests within our reach were, therefore, those of Aitone, Valdoniello, Vezzano, Marmano and Bonifato, the first four being situated in the department of Corte, and the last in that of Calvi, and all intersected by good roads. Those which offer most readily to the eyes of the tourist the finest trees set in the most picturesque surroundings, are the forests of Valdoniello and Marmano. The vale of Asco is almost alone at the present day in being still able to show some ancient trees as yet untouched by the hand of the exploiter, but we were forced to abandon this part of our excursion, which, however, has a place in our plans for the future.

The finest specimens of *Pinus Laricio* we saw did not exceed 19 feet 6 inches in circumference. Trees of 14½ feet to 15½ feet in girth were frequent enough; some of these were more than 130 feet high, but the mean height of fine old trees is about 120 feet. In the forest of Marmano, near to the pass of Verde, the highest and also the best-shaped trees were to be found, the dimensions of these being 11½ feet to 14½ feet around, by 130 feet high. They grow in clumps by themselves or pretty thickly mixed with Beeches and a few Firs. The Laricio in Corsica is found on the slopes of mountains with a marked preference for a northern exposure. Commencing at about 2,950 feet, the limit of the Maritime Pine, it reaches an altitude of about 3,400 feet. At this point it becomes rare, not because it does not thrive at such an altitude, since fine specimens are also to be found at the extreme limit of the forests, but because these highlands are pasturage in summer for flocks of sheep and goats. Outside this high zone replanting from seed is very easy; the great danger to the young forest arises from the risk of fire during the hot, dry, summer months. In the older parts of the forest the risk of destruction by fire is less, the trunks of the trees being stripped of their lower branches and the underwood being generally choked off by Pine. The groups of trees are as close and as regular as in our continental forests of *Picea* and Silver Fir. This is especially so in certain parts of the Aitone forest, which is one of the most regular as regards growth. But the full picturesqueness of *P. Laricio* is best seen in the higher limits of the forests. Here the growth is sparser, because the conditions of existence are harder, but chiefly because the majority of the plants have been cut down by the sheep and goats. In its struggles with wind and snow the tree is not so high; the trunk thickens and throws out some powerful branches, the leader is destroyed, and the crest becomes flat and spreading. Looking at certain Laricios in the vicinity of the pass of Saint Pierre, between the limits of the Aitone and Valdoniello forests, it is difficult not to believe that they are Atlas Cedars, as these grow on the highest of the Algerian mountains.—*Maurice L. de Vilmorin*. Translated in *The Garden* from the *Revue Horticole*.

#### Autumn Flowers in the Pines.

AUTUMN flowers are this year unusually abundant in the Pines owing to frequent rains during the summer. Some of the spring flowers are also blossoming now, and trees are flowering for the second time. *Magnolia glauca* has shown occasional buds and blossoms throughout the entire summer. Handsome flowers of *Rhexia Virginica* and *R. Mariana* are still seen among their pretty urn-shaped seed-pods, and *Ludwigia alternifolia* and *L. hirtella* also mingle their symmetrical yellow flowers with their winged seed-boxes. The long wand-like stems of *Decodon verticillata* are here, too, with their curious trimorphous arrangement of stamens and styles. The relative of this plant, *Lythrum Salicaria*, originally from Europe, but well established in this country, also has two sets of stamens, one longer than the other, and the style is long on some plants, while on others it is short. This is evidently one of Nature's provisions for cross fertilization.

While some plants seem purposely designed to have the pollen carried to different individuals, others, like the stem-

less Violets, are specially adapted for close fertilization. The showy Violets of spring scarcely produce any seed, but depend on the underground flowers of autumn, which do not open at all, but push up their well-filled seed-pods direct from the earth, ripening and scattering the seed thickly over the ground. From one plant of *Viola cucullata* many forms of leaf and flower are produced. A few years ago I took a thrifty plant of this Violet from its wild home and planted it in the garden. The flowers were intensely blue, and they disappeared without forming seeds, but later the cleistogamous seeds were produced in abundance and little plants grew all about the parent. Many of these seedlings are altogether unlike the mother plant. Some have deep-lobed palmate leaves, other plants have smaller light-colored flowers, and there are many variations in leaf and blossom from the one plain-leaved, deep blue-flowered parent. As an experiment one of the seedlings with strikingly deep-lobed palmate leaves was isolated, and similarly varied forms resulted from the autumn seeds. The other two species with cut and divided leaves, *V. pedata* and *V. pedatifida*, do not have this sporting tendency, but remain true to the parent form. The handsome small white Violets, *V. blanda* and *V. lanceolata*, have borne their delicate flowers this month, not as profusely as in spring, but the occasional shy blossoms are particularly welcome as late as this in the season.

*Polygala lutea* is still in flower, as is *P. sanguinea*. Among the Milkworts are also some species which have concealed subterranean flowers as *Polygala paucifolia* and *P. polygama*; the latter species is quite abundant in the Pines. In late summer it bears erect spikes of handsome rose-colored flowers, as well as the hidden fruitful ones. *Tephrosia Virginiana* is delightfully fresh and luxuriant, and is now in bloom. The seeds of this plant and also those of the Wild Indigo, *Baptisia tinctoria*, have been almost wholly destroyed this season by a tiny weevil. The feathery white and flesh-colored spires of Meadow-sweet, *Spiræa salicifolia*, are still found in the damp Pines, and the flowers of many of the compositæ. Blue and purple Asters are abundant everywhere. The Golden-rods are past their prime, but good specimens of *Solidago sempervirens*, our most handsome species, are still found, with large thick shining leaves and fine heads with deep golden rays. *Coreopsis grandiflora*, after a rest of several weeks, has started afresh; its deep golden rays make it the most handsome of the genus, and it rivals *C. lanceolata*. Cone-flowers and Sunflowers are still here. The narrow-leaved *Helianthus angustifolius*, peculiar to our Pines, is full of bloom, and so is *Chrysopsis Mariana*. The flowers of Closed Gentian, *Gentiana Andrewsii*, as well as those of *G. angustifolia*, with large open corollas, are among our treasures in the damp Pines. But the glory of autumn is the ripening foliage of tree and shrub, which is now fast approaching its greatest splendor.

Vineland, N. J.

Mary Treat.

## New or Little-known Plants.

### *Spiræa arbuscula*.

THIS handsome *Spiræa* is an alpine shrub with erect, wiry, branching stems terminating in small compact corymbs of bright rose-red flowers. Its affinities are with *Spiræa lucida*, which is a larger plant with looser corymbs of white or pale rose-colored flowers, and which grows at a low elevation in dry woods from the Black Hills of South Dakota to southern Alberta and eastern Washington, with *Spiræa corymbosa* of the southern Alleghanies and with the Siberian and eastern Asiatic *Spiræa betulifolia*. It differs from *Spiræa lucida* in its dwarfer habit, in its smaller and much more compact flower-clusters, in its bright red stems covered with thin lustrous bark annually exfoliating in thin scales, and in its smaller ovate-elliptical or obovate coarsely crenulate leaves, which, like the young shoots, are slightly puberulous on the lower surface at least while young.

*Spiræa arbuscula*\* grows at Glacier, on the Selkirk Mountains, in British Columbia, and ranges southward along the Cascade Mountains and the high coast ranges of Washington and Oregon and along the Sierra Nevada of California to the centre of that range. On the Olympic Mountains in Washington it forms dense low mats at the timber-line at an elevation of 5,000 feet above the sea, while on Mount Ranier, on the opposite side of Puget Sound, it ascends 2,000 feet higher, enlivening in August rocky cliffs with its brilliant flowers.

This pretty and distinct plant (see illustration on page 413 of this issue) has been successfully introduced into the Arnold Arboretum, where it flowered freely last June, and promises to adapt itself to its new surroundings.

C. S. S.

## Foreign Correspondence.

### London Letter.

**VANDA AMENA.**—Although described and certificated by the Royal Horticultural Society as a new natural hybrid between *Vanda Roxburghii* and *V. cœrulea*, I am inclined to believe this is nothing more than a form of the first-named species with flowers a trifle larger and clearer in color than those of the type. It has exactly the leaves and habit of *V. Roxburghii* as represented at Kew. Whether hybrid or variety, however, it is a pleasing Orchid; the flowers, which are borne in racemes, are two inches across, the sepals and petals checkered with yellow and dusty ferruginous purple, the three-lobed lip, with panduriform mid-lobe, being violet-purple. *V. Roxburghii* is one of the commonest of Orchids in Bengal and other parts of India as well as in Ceylon, and it appears to be variable as to the size and color of the flowers. The ordinary form was figured by Lindley in his *Botanical Register*, t. 506, from a plant flowered in Sir Joseph Banks' garden at Spring Grove in 1819. It is said to prefer the Mango as a host-tree in Bengal. The plant under notice was shown by Messrs. Linden, of Brussels.

**LÆLIA PUMILA**, var. **GATTON PARK.**—Under this name a distinct and beautiful form of *Lælia pumila* received a first-class certificate last week. The type has rose-purple sepals and petals and a maroon-purple lip; the variety *Dayana* is darker in color with a white blotch on the lip, and that known as *præstans* has a trumpet-shaped lip with a yellow disc. There is also a form of the last *præstans* with ivory-white sepals and petals and another called *delicata* with nearly white segments. The new one differs from all these in having the sepals and petals of a pale blue shade, of that peculiar tint called French gray, while the color of the front portion of the labellum is rich blue-purple, with a patch of white in the centre. In the form of the labellum it resembles the variety *præstans*. This plant came from the collection of Mr. J. Coleman, Gatton Park, Reigate.

**DENDROBIUM PHALÆNOPSIS.**—While our Orchid-houses are now gay with the sprays of flowers of this lovely eastern Orchid it is satisfactory to see that the auctioneers are advertising sales of newly imported plump-bulbed plants of it by the thousand. It is emphatically a plant for every tropical collection. Any one who can grow *Nepenthes* or *Ixoras* or *Anthuriums* can manage *Dendrobium Phalænopsis*. Notable characteristics of this Orchid are the elegance of the sprays and the large number of flowers on each when the plants are strong, the variety of color and the delicate blending of the colors in the individual flowers. The close resemblance of the flowers to those of the beautiful *Moth-Orchids*, *Phalænopsis*, and the fact that these flowers remain fresh twice as long, all contributes to make it one of the very best Orchids in cultivation here.

**APERA ARUNDINACEA.**—A first-class certificate was awarded last week to a plant of this graceful Grass exhibited by

\* *Spiræa arbuscula*, Greene, *Pittonia*, iii., 63 (1895).

*Spiræa betulifolia*, var. *rosea*, Gray, *Proc. Am. Acad.*, viii., 381 (not *Spiræa rosea*, Rafinesque) (1872).

*Spiræa lucida*, var. *rosea*, Greene, *Pittonia*, ii., 221 (1891).

Messrs. J. Veitch & Sons. The plant was in the form of a tuft of thin, rigid, erect culms about two feet high, clothed with narrow graceful foliage. It bore panicles of flowers

are so much longer than the culms that they trail on the ground unless the plant is elevated on a pedestal, in which position it is seen to advantage. This character may be

Fig. 53.—*Spiraea arbuscula*.—See page 412.

from two to three feet long which drooped in the most elegant fashion, forming an airy plumose or tail-like cluster, colored pale brown tinged with pink. The panicles

abnormal, for, according to the description and figure of *Apera arundinacea* in Hooker's *Flora of New Zealand*, the panicle is erect and about a foot long: "A tall, erect,

densely tufted, glabrous, most graceful grass. Culms reed-like two to five feet high. Panicle eight to sixteen inches long." It is a native of Northern Island, in New Zealand, and is also found in subtropical east Australia. The genus is closely related to *Stipa*.

**MEGACARYON ORIENTALE.**—A figure of this new garden plant is given in *The Gardeners' Chronicle* this week, where it is described as a remarkable Boraginaceous plant, closely allied to *Echium*, from which it differs chiefly in the smooth, ovoid, not tubercled carpels. It forms a tall coarsely hairy plant with large-spreading oblong-lanceolate basal leaves, and a central leafy flower-scape four feet high bearing numerous flowers in a loosely-branched pyramidal cyme, as in some of the species of *Echium* from the Canary Islands; for instance, *E. candicans*. The flowers are about an inch long and as wide, with a five-lobed limb, colored pink with purplish streaks. The genus is monotypic and is a native of Turkish Armenia. It has lately flowered in the garden of Mr. W. B. Boyd, Melrose, who obtained it six years ago, and it has been growing ever since in a rockery border in rather heavy loam. It is a stately plant for the herbaceous border.

**CRASSULA COOPERI.**—This dwarf species has small fleshy leaves which become tinged with purplish crimson under the influence of bright sunshine. In the autumn it flowers freely, and the bright rose-red of its cymes of tubular flowers are an additional attraction. It may be grown for carpet-bedding or for the rockery in the same way as *Sedum Acre*, *Mesembryanthemum cordatum* and *Alternanthera*, and requires the same treatment as these. It is a native of south Africa, and has been in cultivation about thirty years, but it has only lately attracted the notice of horticulturists. Messrs. G. Paul & Sons, Cheshunt, exhibited a basket of this plant at the last meeting of the Royal Horticultural Society, when it was favorably noticed. It is as easily multiplied as *Sedum Acre*.

**ASCLEPIAS CURASSAVICA.**—This plant is occasionally grown for its decorative character. It is also known as False *Ipecacuanha*, and is said to be used in the West Indies as an emetic. According to the following note, recently published in the *Kew Bulletin*, it has another and still greater value as an insectifuge: "Miss Manning would be greatly obliged if the Director would tell her what the enclosed plant is. It grows everywhere, as a weed, about the Isthmus of Tehuantepec (southern Mexico), and is used by the Indians there to keep away vermin, especially fleas. Miss Manning's friends in Mexico have tried it, and found it most successful. They make a rough broom of it and sweep the floors and walls of their huts, and find that they are not troubled with fleas for a considerable time afterward. They have tried brushing dogs with it when their coats are full of vermin, and it appears to answer the same purpose with them. The Indian name of the plant is *Chilpati*." The plant sent was unquestionably this *Asclepias*. Possibly it is known as an insectifuge to some of the readers of GARDEN AND FOREST.

**EXHIBITION OF FRUIT.**—The great annual exhibition of British-grown fruits arranged by the Royal Horticultural Society was again held this week at the Crystal Palace. Considering that the year has not been a good one for fruit, the display in every class was of surprising excellence. It is difficult for those who do not understand how such exhibitions are made and the special conditions under which, as a rule, the fruit shown is produced, to believe the reports from nearly all parts of the country of poor crops and inferior quality. The tables at the Crystal Palace literally groaned under the piles of superb apples, pears, grapes, peaches, plums, cherries, etc., shown as British produce. As *The Gardeners' Chronicle* remarks, it is a grand advertisement, and one that is needed to teach the populace what first-rate English-grown fruit is. Whether the populace would care to pay the price such fruit would have to realize to make it profitable is another question.

## Cultural Department.

### A Lily-bulb Disease.

IN a full account of the disease which last year attacked the bulbs of Lilies in Japan, Mr. G. Massee recently stated the following facts in the *Kew Bulletin*:

During the year 1896 a destructive wave of fungoid disease almost completely ruined the crop of Lily-bulbs grown in Japan for exportation to Europe. The first indication of this disease received at Kew was through a London dealer, who sent a large number of diseased bulbs for examination. These bulbs formed part of a consignment received from Japan in November last, consisting of 848 cases, containing 73,050 bulbs of *Lilium speciosum*, of the varieties *album* and *rubrum*. Out of this number only 250 bulbs arrived in a salable condition, the whole of the remainder being more or less rotten and worthless. At a later date the same firm received a second consignment of 37,590 very large bulbs of *Lilium auratum*, and of this quantity only 4,000 were salable. Similarly diseased bulbs, received from Japan, were afterward sent to Kew for examination from other sources. Finally, a quantity of bulbs obtained through an agent from Japan, for planting at Kew, contained a large percentage suffering from the same type of disease.

The bulbs received for investigation showed every stage of disease; in the earliest condition the base of the bulb is alone discolored and somewhat soft; this discoloration and softening of the tissues gradually spreads from the base, until finally, in the most advanced stage, every part of the bulb is of a brownish color, and sufficiently soft to admit of being readily crushed into a pulpy mass between the fingers.

Microscopic examination revealed the presence of slender, continuous, hyaline, branched hyphæ traversing the tissues in every direction; the cell-walls are never pierced, but gradually dissolved, and it is only at the last stage of the disease that the starch grains become irregularly corroded and gradually dissolved. So long as the epidermis of the bulb-scales remains intact there is no trace of mycelium or fructification on the surface, but when the tissue is reduced to a soft pulp, or when a diseased bulb is cut open, the broken surface is within twenty-four hours covered with a dense snow-white mycelium, which within three days becomes studded with numerous clusters of fruit, resembling to the naked eye miniature pins with round black heads. The occurrence of this particular form of fungus on every bulb examined suggested that it might possibly be in some way associated with the disease, and subsequent cultures and inoculations proved this surmise to be correct. The fungus grows readily as a saprophyte; the spores germinating and forming the characteristic superficial white floccose mycelium, which within a week bears an abundance of fruit, on such varied culture media as prune juice, sterilized potato, decoction of bulb scales, etc. In one experiment four spores were sown in a five per cent solution of cane sugar in water in a Petri dish, and at the end of six days the entire surface of the liquid was covered with the fungus in a fruiting condition. When spores were sown in a hanging-drop alone with a very thin section of Lily-bulb scale, it was observed that the germ-tubes could not enter the tissue through the epidermis, but that they entered readily at those points where the cells were not protected by the epidermis.

A set of experiments was also carried out, using healthy Lily-bulbs. Numerous experiments were made with other kinds of bulbs, and it was found that the fungus refused to grow on onions, however much mutilated. On the other hand, Daffodil-bulbs were very susceptible to the disease; if the roots were broken, or a wound made in the bulb, and afterward powdered with the spores, the disease showed itself within a few days, and was in due course followed by the characteristic fruit of the fungus. It was invariably found that, however much bulbs were mutilated, and then inoculated with fungus spores, submergence for a few minutes in a one per cent solution of salicylic acid or corrosive sublimate prevented the disease; in other words, all fungus spores coming in contact with the above-named solutions are destroyed, whereas the vitality of the bulbs thus treated is not at all affected.

Dr. Halsted has described a somewhat similar disease, called "soft-rot," as attacking the Sweet Potato in the United States. The fungus causing this disease, *Rhizopus nigricans*, Ehrh., is closely allied to the species under consideration causing the Lily-bulb disease.

In a summary Mr. Massee concludes that the Lily-bulb disease is caused by a parasitic fungus called *Rhizopus necans*;

the fungus cannot penetrate the unbroken tissues of the bulb, but gains an entrance through wounds, more especially broken roots; the amount of evidence forthcoming indicates that the bulbs are not diseased until after they are removed from the ground; the spores of *R. necans* are killed by a short immersion in a one per cent solution of corrosive sublimate or of salicylic acid. Neither of these substances have any injurious effect on living bulbs, provided they do not remain in the liquid for more than fifteen minutes.

The fungus is by no means confined to Lily-bulbs for its food; but, as experiments have proved, can live on a great variety of dead or decomposing substances; it may also occur as a parasite on other plants than Lilies in Japan, as it readily attacks and destroys Daffodil-bulbs. Judging from the enormous amount of injury caused, it would appear that the fields where the Lilies are grown must be saturated with the fungus, growing indiscriminately on various substances, and attacking the Lily-bulbs, along with other things, as a matter of course. If practicable, entirely new localities should be selected for the work. Even if this were done, great care would have to be exercised, so as not to introduce the fungus; the spores are readily conveyed from one locality to another in the soil on tools, cart-wheels, shoes, clothing, etc., in addition to being carried by wind or animals. An important point to remember is not to allow vegetable rubbish of any kind to accumulate, and all diseased bulbs should be burned and not allowed to remain on the ground, otherwise the zygospores that form on such old decaying bulbs would start the disease the following season. As little injury as possible should be done to the roots of the bulbs when they are removed from the ground, and the bulbs should be allowed to "sweat" before they are packed for exportation. If the fungus is known to be present when the bulbs are being prepared for packing, they might be placed in a solution of salicylic acid as advised. The sterilized earth in which the bulbs are packed appears very suitable for the work, and cannot be in any way considered as a cause of the disease.

### Work of the Season.

SPRING-FLOWERING bulbs have all been received, and should mostly be at once planted. Long exposure to the air is injurious to all bulbs. Those intended for outdoor planting usually have to await the removal of tender bedding plants from the ground. In the preparation of the beds for bulbs it should be remembered that the soil has been more or less exhausted by summer bedding plants, and therefore deep digging and an application of thoroughly-rotted stable-manure are necessary. I have tried prepared fertilizers in Tulip-beds, but these have not proved better than stable-manure. The latter is really preferable in a stiff soil, and makes it more open and friable. The advantages of winter mulching for Tulips and Hyacinths have been questioned of late years, and in the latitude of Philadelphia it does not seem to be necessary if the bulbs are planted at the proper depth, so as to prevent their being heaved out by frost. Tulips intended to be forced for cutting can be handled most conveniently by the method used by florists; that is, by planting about fifty bulbs of one variety in a flat or shallow box, giving them a thorough watering and storing the boxes in a cold frame; here they are covered with earth to a depth of about four inches, and remain until needed for forcing.

For conservatory or house decoration several bulbs of Hyacinths or Tulips planted in an eight or ten inch pan are effective, and the same plan answers for Freesias, Daffodils and Lilies-of-the-valley. Flats of Lily-of-the-valley, for cut flowers, may be treated in much the same way as that noted for Tulips, except that the Lilies should not be covered to a greater depth than two inches. This is sufficient to prevent them from drying out, and allows the frost to penetrate readily to the pips. It is also much easier to remove the covering of earth from the boxes in frosty weather if a thin layer of long litter is shaken over the pips before covering them with earth, and there is less danger of snapping off the pips in the process of uncovering. The trimming of the roots of Lily-of-the-valley at the time of planting in either pots or boxes is another point observed by many successful growers. This permits the pips to absorb moisture more readily, and abundant water is necessary to the successful forcing of these plants.

In the forcing of Freesias and Roman Hyacinths, both admirable in the conservatory, root-growth is needed first, and, therefore, but little heat should be allowed these plants in the early stages of growth. The same rule applies to the ordinary Dutch Hyacinths.

*Lilium longiflorum* and *L. Harrisii*, which are now well started, should be brought in from the frame before hard frost comes. Moderation in watering is a good rule for these plants during the early part of the season especially. But little syringing is needed; the only insect likely to trouble them at this time is the green aphid, and this is readily disposed of with applications of tobacco-water or tobacco-dust. The large clumps of these Lilies, so much used in Easter decorations, usually comprise several plants started in small pots and afterward placed together in a large pot. This method permits the selection of plants that are all in the same condition of growth, and ensures a more even crop of flowers than would be possible if the bulbs were started together in a large pot.

Most of the Caladiums have finished their growth for this season and will be going to rest; while these shall not require much attention from this time on until spring, a watering as often as once a week or ten days will help to prevent dry rot if the pots are stored beneath a dry stage in the greenhouse.

Richardias and hybrid Amaryllis are also among the valued bulbs for winter and spring flowering, and having been properly rested may be started moderately now. Amaryllis enjoy a temperature of from sixty-five to seventy degrees; this is higher than is needed for Richardias, while both appreciate rich soil and abundant watering.

Holmesburg, Pa.

W. H. Taplin.

### The Hardy Plant Border in October.

THE borders may still be kept bright with a good selection of hardy perennials. The best and showiest plant now bearing blue flowers is *Salvia azurea grandiflora*. This Sage grows luxuriantly in a warm sunny spot in light soil. A thick layer of dry leaves is sufficient protection here. *Sedum Sieboldii* is still flowering freely. Although this pleasing plant thrives on the front row of the herbaceous border, its choice of position is a dry sunny place in the rock garden; here its stems droop gracefully over the rocks, and its pinkish flowers, which are produced in much-branched umbellate cymes and last in good condition for several weeks, are seen to better advantage.

The neat perennial *Eupatorium coelestinum*, or Mist-flower, carries compact cymes of blue flowers at this time. The native Dittany, *Cunila Mariana*, is a neat much-branched plant with small purple flowers produced in corymbed cymes. It is attractive now in the front row of the herbaceous border, and is perfectly hardy here.

One of the neatest and showiest of the native Asters for use in the border is *A. turbinellus*. It is of easy cultivation and increases rapidly. Large plants may be placed about six yards apart in the back row of the herbaceous border, and their large bright blue flowers make a fine display at this time. Another distinct and showy species is *A. sericeus*. The slender stems of the plants, which are two feet in height, are thickly clothed with pubescent leaves of a silky white color. The flower-heads are large and the ray-flowers are of a deep violet color.

*Solidago rigida* is a good companion for these Asters, and takes kindly to cultivation. Another graceful and showy species of Golden-rod for the border in late autumn is *Solidago Drummondii*. This western species grows luxuriantly here; its drooping stems are from three to four feet long.

The white Japan Anemone, *Anemone japonica alba* or Honorable Jobert, is a handsome hardy perennial when in flower. The plants are unusually floriferous this season and have healthy foliage. They are grown in a slightly shady position and somewhat moist soil. A liberal top-dressing of well-rotted cow-manure was applied to them last autumn. The white flowers of this plant are among the best we have for cutting at this time.

*Ceratostigma plumbaginoides*, better known in gardens as *Plumbago Larpenæ*, is still producing an abundance of its violet flowers and helps to brighten the border. *Callirhoe involucrata* and *C. verticillata*, prostrate hardy perennials which belong to the Mallow family, have large violet-crimson flowers which are now plentiful. *Cedronella cana*, a labiate from New Mexico, of neat, erect habit, is now bearing its showy, purplish flowers. A few other desirable plants now flowering in the border are *Chrysopsis villosa*; the pink-blossomed *Eupatorium purpureum*; *Polygonum Virginianum*; the near relative of *Helianthus*, *Actinomeris squarrosa*, known also as *Coreopsis alternifolia*; the purple-flowered *Boltonia asteroides*; *Clematis Lavalleyi* and *C. Savatieri*; *Colchicums*, *Gaillardias*, *Potentilla recta*, *Geranium Wallichianum*, *Hieracium umbellatum*, *Aster Shortii*, *A. laevis*, *A. Novae-Angliae rubra* and *A. amethystinus*.

## Correspondence.

## Some Questions of Color.

To the Editor of GARDEN AND FOREST:

Sir,—A commentator upon Nature's beauty in a recently published book speaks of the "even yellow" which the Sugar Maple assumes in the autumn. And another writer, trying to decipher the mysteries of the coloring process, says that while every shade of the golden and ruddy hues is seen in the forest, each species of tree keeps to a tint of its own. Such careless generalizations are contradicted, of course, by the witness of any autumnal forest in eastern America, and in south-eastern New York an astonishing diversity is shown this autumn in the behavior of trees of the most prominent species.

Our forests were nourished by much rain in July, and afterward were not scorched by many burning days. Up to the time when they began to assume brighter tints their foliage, as a whole, was almost as full, as succulent, and as freshly green as in June; and now that cold nights and sunny days have alternated for a time, the untouched Maples, Oaks, and Sassafras-trees still keep their luxuriant June-like aspect, while their changed companions display their reds and yellows and browns in unusually magnificent masses; these often seem even thicker and more sumptuous than the green trees because variety in the coloring throws the richness of each branch, twig and tuft of leaves into strong relief.

This is preëminently a region of hills, range lying beyond range and shoulder rising above shoulder with only narrow strips of valley between. One must drive a good many miles up and down hill before coming out on high rolling districts whence the dim outlines of the Catskills are discerned in the far distance. And it is preëminently a region of forests. Only the more level stretches are cleared and farmed and dotted with houses and tiny villages where great Maple-trees show their most splendid hues. Elsewhere everything is woodland, broken only by a few meadows along the margin of the railroad, the little lakes and the streams, and a few partially cleared spots where hopeful or shiftless settlers or where summer residents have established themselves. It is all second-growth forest, of course. A few ancient giants reveal themselves here and there, but for the most part the lover of individual trees would find much fault with our woods. Nevertheless, the hills, when viewed as a whole, seem as beautifully clothed as they can have been by the aboriginal forest. Nowhere are there such signs of long-past burnings as we find in many parts of the Catskills or about Lake George, and nowhere such proofs of more recent devastation as are frequent in the Adirondacks. There are here no blackened stumps to declare the vandalism of man. As far as the eye can reach and the fancy can extend, the thick garment of the hills is torn only by massive outcropping ledges and precipices of rock. One may drive mile after mile, and except for the road upon which one travels and an occasional small-cleared space, the landscape appears as the Indians themselves beheld it. Yet this region is less than forty miles from New York, and only a few miles beyond begins the fertile and thickly-settled region of which the beautiful town of Goshen is the centre.

Few other regions so near a great city can show such broad effects of autumn colors, spreading out and reaching over range after range of hills. And the color is especially rich and varied here, for the admixture of evergreen trees is just sufficient to enhance that of the deciduous trees without making it spotty and confused. I have seen similar panoramas of wooded mountains in the Pennsylvania Alleghanies. But there the coniferous trees were so abundant that the effect so charming here was lost—an effect of infinitely varied yet always suave and delicately blended colors, rivaled in harmony among the works of man only by the coloring of old India shawls. There are no stiff and spiry Firs and Spruces in this region; only White Pines and Hemlocks, softer in outline and texture, and not a great many of these. The general tone of the hillsides is supplied by the yellows and browns of Oaks and Beeches, and it is accentuated in the most harmonious way by ruddier Oaks, more coppery Hickories, and Maples which show like balls of gold or tall feathers of scarlet.

Our Sugar Maples are aglow in every shade of brightest yellow, of flaming red, of clearest green and burning orange, mingling together, in the larger trees in the cleared spaces, with a brilliance exceeding that of anything else which Nature produces. The radiance of jewels is relative dullness in comparison if the sun is shining on the most gorgeous Maples in this season of brilliant coloring. And yet almost more beautiful, and, I think, less commonly seen, are certain Swamp Maples which are not yellow or red at all, but pink—pink of

that shade which, if a milliner's term may be borrowed, is called "old rose."

Almost this same color appears also in the Dogwoods, together with several other colors: a dusky purple, an almost orange-red, a dull dark crimson and a pale ashes-of-roses hue. The Ash is still another tree which assumes a wide range of color, and varies between a dusty plum-color and a pale yellow. Many of the Sassafras-trees are multitudinously variegated, almost every leaf streaked with red, green and yellow, as though each was anxious to show the three prominent colors which October has chosen for its heraldic shield. Again, if we group the various kinds of Oaks together, we get a gamut of tints which runs from the darkest maroon to yellows of a golden, a copper and a brazen quality.

Perhaps some day an observer scientific enough to explore the laws of plant-growth even more minutely than they have yet been explored, and patient enough to watch the same trees carefully year after year, may, in part at least, read the riddle of these seemingly lawless variations. One thing to be studied will be the question in how far any weakness in a tree or in any of its parts accelerates the coming and affects the character of the autumnal change. We have all seen the leaves on a branch half-broken from its trunk turn brilliantly while the rest of the tree remained green. But, on the other hand, one which appears as vigorous as its fellows may turn a bright gold or blush a vivid red and stand out as a great isolated bouquet from the verdant masses about it. Does this branch also in some way and to some degree lack vitality, as the half-broken one so evidently does?

Again, if leaves turn as they dry, or dry as they turn, why are the well-watered trees in swamps so apt to be the first to show bright colors? And the effects of light need also to be studied. Here, for instance, is an Ash-leaf picked up from the ground. Some of its leaflets had partially overlapped the others, glued to them, probably, by moisture. The exposed surfaces are a soft plum-color, while the surfaces which had been hidden are a clear yellow. On the other hand, Beech-leaves which had similarly clung together I have found to be of a bright yellow color where the light had struck them, and of their normal green where they had been concealed. Light seems to have played a controlling part in these diversities, as it sometimes seems to do when only the tips of Maple-boughs grow vivid. But, on the other hand, a White Oak beginning to turn will show deep red leaves, not gathered on a single branch or tipping isolated shoots, but sprinkled singly all over the tree, and as often near its trunk and on the under side of its branches as where the sunshine falls more fully.

Tuxedo Park, N. Y.

M. G. Van Rensselaer.

## In Nature's Own Domains.

To the Editor of GARDEN AND FOREST:

Sir,—To travelers who reach the far frontier the richness of the native flora of the prairies and woodland is a surprise and pleasure. Wherever the sod is yet unturned, or the verdure unchecked by close grazing, it is like a rainbow-hued flower garden in which one may wander and gather at will and yet leave a world of bloom behind. Nor are the banks of the rivers or the shores of unfrequented ponds much behind the prairies and woodlands in the rare beauties displayed. The snow-white Water-lily floats on the still waters. A fringe of scarlet and blue and white sweeps the water's edge, where the bright-hued Cardinal-flower and Lobelia are established, while the sweet breath of the neighboring Clethra fills the air.

But on the unbroken prairie and the unfrequented woodlands are the chief surprises. Everywhere are plants and flowers unknown to us. There is a grace and charm about these wind-tossed flowers that by contrast make the ordinary flowers in trade appear ugly and stiff. Taken from their native haunts, with no longer the cloudless blue sky above them, and the loving comradeship of thousands of their own kind about them, where they no longer nod to the prairie breezes or peep through the vailing prairie grasses, the charm of many of the wildings vanishes. They are then poor and weedy, and consigned to quick oblivion by the gardener.

But the beauty of some of these denizens of the wild wood survives even in our hard, formal borders. The Liliun superbum, with its tall column of clustered nodding flowers, is rich and stately whether blowing at will on a western plain or planted in a park. Cultivated Orchids from far countries are not more beautiful than their American relative, *Cypripedium spectabile*. Their curiously twisted and inflated blooms, satiny white, with clouding and needle-like rays of softest pink-purple, are plentifully borne on plants transferred to a shaded hillside or water edge.

In the edge of the open woodland may be found the yellow Violet with tiny Pansy-like flowers of a hue unlike anything known in any cultivated Violets. A man of fastidious tastes once said but two flowers are golden without being hard or metallic, the yellow Rose and the wild Violet of the hedgerows. Later, in the same woodland, the Fringed Gentian is found. Blushing Rue-Anemones, deep pink Sabbatias, Lily-like Erythroniums, dainty Ferns and Dicentras, blazing Fire-pinks and glowing Golden-rods come in cheery succession from springtide to autumn.

Pineville, Mo.

Lora S. La Mance.

### A Winter Plantation.

To the Editor of GARDEN AND FOREST:

Sir,—I wish to make a small winter plantation but have not sufficient knowledge of shrubs and trees to compose a harmonious planting, and so ask for your suggestion. It is desired to make this planting on a lawn looking to the south and terminated on the street boundary by a retaining wall of rustic stone about five feet high. The space to be planted is on the end adjoining the wall and between the walk leading to the house entrance and a Maple fourteen feet from the walk, this tree being about eighteen inches in diameter. The Maple is conical in shape, the result probably of early pruning. The branches are high above the ground, so that the lawn under the tree receives considerable sunlight. The purpose is to make an agreeable winter plantation visible from the living room sixty-five feet distant from the street. There are other shrubs on the lawn.

The trees from which it is desired to make selections are Black Alder, Thorn, Cranberry-tree, common Barberry, Euonymus alata, Pyrus arbutifolia, Andromeda Mariana, Kerria, Ink-berry, Red-twigged Dogwood and Cotoneaster vulgaris.

Robert A. Kutschbach.

White Plains, N. Y.

[The list of shrubs suggested by our correspondent is, on the whole, a good one. For the purpose he indicates Berberis Thunbergii might be added to it, as it is one of the best winter-berried shrubs in cultivation. The most showy of our Thorns in winter is probably Crataegus Crus-Galli, although perhaps this tree would be too large for such a position. Euonymus alata, although very ornamental in the autumn when its leaves turn rose color, is not a particularly desirable winter plant, as the fruit is small and inconspicuous; and Andromeda Mariana, which produces beautiful flowers, has not showy fruit.—Ed.]

### Rusty Appearance of Elm Leaves.

To the Editor of GARDEN AND FOREST:

Sir,—I enclose some leaves of Ulmus Americana with the request that you will explain the rusty appearance of their under side, which I suppose is the work of some insect I have as yet been unable to detect. On my lawn and in my garden in this city are a number of seedlings of this species from three to five years old. These have flourished thus far, and some have made upward of three feet of new growth during the present season. They have had sufficient water, the entire trees having been sprayed quite frequently, but not to excess. About the first of August the leaves of nearly every one of the Elms began to show the rusty appearance of the enclosed leaves, and in some cases they have become dead, the rust showing through to the upper surface, and some have dropped off the tree. I have watched the trees closely and have been unable to detect any insects preying upon the leaves.

Some specimens were sent to Professor A. D. Hopkins, Entomologist of the West Virginia Agricultural Station, and his reply is as follows: "I have examined the leaves of Ulmus Americana enclosed in your letter to me, and while I fail to find insects of any kind, the character of the injury would indicate that it is due to the presence of a very minute mite, working on the under side of the leaves. If so the best remedy you can apply is to spray the trees with water, applying it very thoroughly and with as much force as possible. Of course, you cannot do much good now, but if you will begin next spring before the leaves are injured I think you will be able to prevent the recurrence of the trouble."

I myself fail to find any evidence of the existence of the Elm-tree beetle which has ravaged the Elm of the east. Professor Hopkins states further on in his letter that he does not ascribe the trouble to the Elm beetle. As I have said already, I have tried the remedy which he suggests, that is spraying the trees thoroughly with water, but without good effect.

The rust has apparently not affected or injured the growth of the trees, and they have made a rapid growth and appear perfectly healthy otherwise. Only a portion, perhaps one-third or one-half of the leaves, appears to be affected, and the remainder keep their fresh appearance. The leaves affected are almost invariably the older ones, but are on the new growth as well as the old. September has thus far been so warm that the trees are still growing. I note upward of two inches of new growth on some specimens since the first of September.

I am the more disappointed on account of this trouble because I have advocated the planting of Elms in the outskirts of this city, and have induced my neighbors to cultivate seedlings native to the immediate neighborhood. The soil on my lawn and garden is the regular prairie alluvium mixed slightly with coarse sand, overlaying a thick strata of yellow clay under which is the blue or tunnel clay of the region. The land was formerly cultivated, but when I took possession it had lain fallow for several years, being covered with natural prairie grass and weeds. Nothing has been done to it except to level it up with the same kind of soil, with almost no application of fertilizer. It seems to be rich enough for all kinds of vegetation, for flowers in great variety and vegetables have grown luxuriantly this season, as has the grass on the lawn proper, although but little watering has been done owing to the pressure in our water-mains. My place is eight miles from the business portion of the city and there are no gas-mains in the neighborhood, electricity or oil being used for lighting; and there are no factories near by. No external influences to cause leaf-blight are apparent. Seedlings of Fraxinus Pennsylvanica, Acer Negundo, Ulmus fulva, Fraxinus Americana, Acer barbatum, Tilia Americana, Alnus rugosa, Populus monilifera, Catalpa speciosa and others are all healthy and flourishing, and unaffected either by insects or disease, and all of these have made rapid growth since the first year, except Tilia Americana, which, though healthy, has grown very slowly.

I am much impressed with the fitness of Fraxinus Pennsylvanica for the soil and climate of this locality. Although not so rapid a grower as some of the other species named, it still makes satisfactory growth. Fifteen-year-old trees in this neighborhood have reached a height of thirty feet and a trunk diameter one foot from the ground of from six to seven inches. The great value of the species is its absolute freedom from all diseases and from the ravages of insects and vermin of all kinds. During a long residence in this section and careful study of the species (which is indigenous to this immediate neighborhood, and quite abundant along the headwaters of the north branch of the Chicago River and along the Des Plaines) I have never found the tree subject to disease or insects. The only objection to it is that it seldom grows to any great size, though fairly long-lived, and is therefore hardly suited for a street-tree where much shade is desired. It is, of course, also somewhat objectionable on account of the late development and early falling of its foliage. This tree flowers and fruits abundantly along the streets in this immediate neighborhood, and I have had excellent success in planting the seeds. I find that it bears a good deal of hard usage, though it is apparently grateful for care and cultivation. Some handsome trees of this species grow near by. The natural crown is conical, but there is no difficulty in producing a wide round head by judicious pruning.

Catalpa speciosa has been planted quite extensively in this neighborhood, and, although a native of the southern part of Illinois, it does not do well in this latitude. It flourishes for a few years, blooms luxuriantly in season, bears an abundance of fruit, but after a time sickens and dies, apparently decaying from the heart outward. The whole trunk often becomes a mere shell before the north-west gale rends it apart. It shoots quickly from the roots and makes a wonderful growth for the first two or three years, but, in my opinion, it is absolutely worthless in this section.

Alnus rugosa does well when only a small tree is desired, but it is often infested with vermin, and at times is greatly troubled with the same borer that attacks the Maple family.

If Ulmus Americana is not hereafter subject to blight and rust, as shown by the enclosed leaves, I am inclined to recommend it as the most desirable tree for planting in our streets, but I have noticed a great deal of this blight during all of this season in old as well as young trees.

Irving Park, Ill.

O. S. Whitmore.

The leaves of Ulmus Americana have been examined with a compound microscope, and I do not find any fungus doing the work that results in the discoloration of the leaf that Mr. Whitmore has naturally enough termed "rust."

At this time of the year Elms are showing the same condition quite generally with us. As a test I went out to a tree standing near the Experiment Station building, and the first branch examined showed leaves that closely matched those which came from Irving Park, Chicago.

When this discoloration occurs in October it may well be called the phenomenon of natural death, but the cause or combination of causes that led to it in the case under consideration I am not able to name. Professor Smith thinks that insects of various sorts often hasten this decline. Lack of sufficient moisture or food material may bring about similar results.

New Brunswick, N. J.

Byron D. Halsted.

### Notes.

Friday, October 22d, has been set apart by the Superintendent of Public Instruction of Pennsylvania as Fall Arbor Day.

The manufacture of beet-sugar was begun in Rome, New York, October 6th, in the first factory operated east of the Mississippi River. The company expects to use about 20,000 tons of beets this season. Tests of beets grown in the vicinity showed from fifteen to seventeen per cent of sugar early in the season, and fully ripe beets will yield a larger percentage. Thirteen per cent is needed for profit.

Professor Cockerell writes us from Mesilla, New Mexico, that on September 22d of this year, Mr. Alexander Craw found some Bamboos, from Japan, which were about to be landed at San Francisco, to be badly infested by a small white scurf-like scale. This proved to be *Aspidiotus secretus*, originally described by Professor Cockerell last year from specimens taken by Mr. Takahashi in Japan. The same insect has been found by Mr. E. E. Green in Ceylon. Growers of Bamboos in this country should be on the lookout for it to prevent its getting a footing here.

In a paper read a week ago before the New York Gardeners' Society, Mr. John E. Lager gave an account of his recent experiences in collecting Orchids in South America. It was stated that Coffee plantations have taken the place of extensive forests where Orchids were formerly found. The *Cattleya* region has suffered most, as the elevation and temperature favorable to *Cattleyas* are also desirable for the Coffee-tree. The South American Andes is said to be the richest section in useful species in the world. The vagaries of Orchids as to habitat were touched upon, and the costliness of Orchids was explained in their comparative scarcity and the inconveniences attending their collection and transportation. Simplified methods of cultivation were described which have led to the more general growing of Orchids, and the sale of cut flowers was also credited with bringing these plants into popular favor.

A comprehensive and interesting account of the Establishment of Public Parks in the City of New York, read last April before the Historical Society of this city by Mr. Gherardi Davis, has recently been published under that title in a neat pamphlet intended for general distribution. After a brief statement of the necessity of public parks in cities and the desirability of guarding them against encroachments, the history of the park movement in New York City is given, beginning with the suggestion made in a letter published in the *New York Packet* in 1785 and addressed to the mayor and aldermen, in which it is stated that "there is not in this great city one proper spot where its inhabitants can enjoy with convenience the exercise that is necessary for health and amusement." The history of Bowling Green, the Battery, and the various squares and parks of the city is told from the time they were proposed until they were acquired by the city and developed as public pleasure-grounds. Facts and incidents are here brought together which are not found in any other publications with the exception of the fragmentary and disconnected records in park reports and occasional newspaper and magazine articles. Some park boards have not complete sets of reports in their own offices, and until recently no systematic effort was made to bring together sets of such reports in any of the important public libraries. Information on this subject cannot fail to be of value to persons interested in public parks, which have come to be an important factor in the development of American communities. The Park and Outdoor Art Association, of which Mr. Warren H. Manning, of Boston, is the secretary, is bringing together as complete sets of park reports and of other publications relating to outdoor art as it is possible to obtain. This particular pamphlet should be the forerunner of similar publications in other cities.

A Horticultural Department has this year been established in Berea College, at Berea, in south-eastern Kentucky, and in addition to class-room instruction there will be manual training in garden and nursery work. This introductory work will be followed by a more extensive course of study which will include the botany of cultivated plants, geology of soils, elementary agricultural chemistry and entomology. With the preparatory botanical study of the native forest-trees it is proposed to offer a short practical course in forestry as being of special value to the students. This portion of Kentucky comprises a region of low mountains originally well covered with hardwood timber and some Pine. While much of the valuable timber has been cut away near the railroads and along streams where rafting is possible, much timber of good quality still remains in more inaccessible places, and forest products must always constitute an important source of wealth in this portion of the state. The college is situated at the foot of the hills skirting the famous Blue Grass region of Kentucky, and the campus of forty acres of natural-forest park contains remarkably good specimens of White and Post Oak, Red, Black, Scarlet and Shingle Oak, Chestnut, Hickory, Sour Gum, Maple and Cherry. Such conifers as have been planted have grown remarkably well. The Horticultural Department of the college was formally inaugurated on October 5th in the delivery of a lecture on the Value of Special Education for Farmers, by Professor S. C. Mason, who is in charge of the department, and two thousand farmers in the vicinity were specially invited to attend. Sound instruction along these lines cannot fail to stimulate the farmers of that section in a more general and successful cultivation of garden, field and orchard crops and in the profitable use of woodlands.

Late varieties of peaches are still coming from New Jersey in small lots, and from western New York and the mountains of Pennsylvania. Bartlett pears held in cold storage are supplied from the Hudson River district and from Massachusetts; other pears grown in the east and now in our markets are Beurre Bosc, Beurre d'Anjou, Beurre Clairgeau and Kieffer, with the first shipments of Duchesse, Reine Claude and Copper plums, with a few Damsons and French and German prunes, are yet seen. During last week less than 51,000 barrels of apples constituted the supplies for this city. Since September 1st 162,485 barrels of this fruit have been sold here, less than half the quantity handled during the same period of last year, and the exports of apples from this country are thus far but thirty per cent of the quantity shipped up to this date in 1896. The first Catawba grapes, from western New York, are now here. Grapes comprised the larger part of forty-nine car-loads of fruits from the Pacific coast sold here during last week. Varieties of this western fruit now in season are the showy Flame Tokay; Black Cornichon, the long berries on loose, shouldered bunches; Emperor, a superior grape for shipping, with oblong, deep rose-colored berries; Black Morocco, less highly esteemed than some other sorts; White Muscat of Alexandria, with musky flavor; white Malaga, the oval yellowish green berries covered with a white bloom, and Black Ferrara, a favorite for home use and for shipping. Italian and German prunes are still coming from Idaho, and Coe's Late plums, from California. Glout Morceau and Winter Nelis were among the pears received from California, and Doyenne d'Alencon, Duchesse d'Angouleme, Beurre d'Anjou, Beurre Clairgeau, Louise Bonne of Jersey and Winter Seckels. The latest arrivals of peaches from the west include Salways, George's Late Cling, and Levy's Late, also a clingstone. Florida and Jamaica oranges and grape-fruit are in limited supply. Cargoes of fruit from the Mediterranean include new crop currants, figs and Almeria grapes, besides lemons and oranges, and quinces of very large size, from Italy.

By the death of Charles A. Dana American horticulture has lost one of its most conspicuous figures and liberal patrons, and GARDEN AND FOREST one of its most valued contributors. The keenest pleasures of Mr. Dana's later years were found in his garden at Dosoris, on Long Island, where he had gathered one of the richest collections of conifers and other hardy trees and shrubs that has been made in this country. Few men who are not professional botanists had a broader and more exact knowledge of coniferous trees, and he lost no opportunity to increase his knowledge and improve and extend his collections. Deeply interested in the future of American forests, he has always been one of the most persistent and intelligent advocates of forest preservation in this state and on the public domain; and in him the parks of this city have always found a vigorous and intelligent champion.

## The Massachusetts Audubon Society.

THE work of this society, founded three years ago for the protection of wild birds, has been active in circulating literature relating to them and in making known the provisions of protective bird laws, and has been conspicuously successful. It has now 1,747 life members, 330 associates, 20 life associates and 110 local secretaries. Following the lead of Massachusetts, Pennsylvania, New York, Illinois, Colorado, New Hampshire, Wisconsin and the District of Columbia have organized similar societies, and several other states are preparing to form Audubon societies. During the last year the Massachusetts Society has issued and freely sent out a number of publications relating to the protection of birds and it is now distributing at a trifling cost an illustrated paper by Miss Florence A. Merriam, entitled *How Birds Affect the Farm and Garden*.

In this publication gardeners who have not studied our native birds and their habits will find a great deal of useful information and that many of their preconceived ideas about our familiar birds and their damage to growing crops have been erroneous. Our common and friendly catbird, for example, is often prosecuted because it eats fruit, and although in some parts of the country it is to a certain extent a fruit-eater, one-third of its food is now known to consist of insects which annually destroy a large part of the farmer's and gardener's profits; even as a fruit-eater it has been demonstrated that it prefers wild fruits to cultivated, most of the complaints of depredations against the catbird coming from those parts of the country where wild fruit is scarce, and actual experiment shows that it prefers red mulberries to cherries and strawberries. The kingbird, having been long accused of destroying honeybees, a careful examination has been made of 218 stomachs of this bird. Insects were found to form about ninety per cent of the whole food, but only fourteen of the 218 stomachs contained any trace of honeybees, while it was found that it had destroyed a number of the bees' worst enemy, the robber fly, which has been known to kill 140 honeybees in a day. The kingbird, too, feeds upon other harmful insects, the gad fly, the Clover-leaf weevil, the destructive Rose chafer, ants and grasshoppers.

The chickadee is shown to be a voracious feeder on the eggs of the canker-worm; and the crow, although he does

pull up some corn and is too often maligned and abused, does infinitely more good than harm. Twenty-six per cent of his entire food has been found to consist of insects, most of which are grasshoppers, may-beetles, canker-worms and other species injurious to growing crops. He is a great devourer, too, of field-mice and other harmful rodents, and he is one of the best scavengers. Greater injustice even has been done to hawks and owls which are persecuted unceasingly, although a majority of them work night and day to destroy the enemies of the husbandman. There are only three common inland hawks in the United States which do any damage; these are the goshawk, which is rare in this country, except in winter; Cooper's, or the chicken hawk, which is destructive, especially to doves, and the sharp-shinned hawk, which feeds principally on small birds. The other so-called birds of prey in the United States are mainly beneficial, and their protection and preservation are of extreme importance. Their food consists largely of meadow mice, rabbits, chipmunks, small snakes, grasshoppers, spiders and centipedes. Swainson's hawk is the great grasshopper-eater in some of the western states, and it has been estimated that 300 of these birds have saved in a month sixty tons of produce that grasshoppers would have destroyed. Owls, too, are great destroyers of small rodents, and the story is told of the nest of one pair of barn owls from which 454 skulls were taken, of which 225 were meadow-mice and 179 house-mice.

Miss Merriam, although she pleads so eloquently and logically for the preservation of our native birds, regards the introduction of the English sparrow into this country as an unmitigated evil. First introduced in 1850, it has now become established in thirty-five states and territories, and has been shown to interfere with seventy kinds of our native birds, most of which build their nests in the neighborhood of houses or in gardens, and are beneficial to the farm and garden. An examination of 522 stomachs of the English sparrow has shown that it feeds principally on wheat, oats and corn, and is but little interested in insects, and that when it does eat insects these are more often beneficial than injurious. It would seem clear then, as Miss Merriam insists, "that the English sparrow should be exterminated, that laws protecting him should be repealed, and that some intelligent systematic action should be taken to rid the United States of his obnoxious presence. Bounty laws cannot do this, for, as has been clearly demonstrated, they do more mischief than can be easily remedied, as money is usually spent on the heads of the valuable birds that have been mistaken for the injurious ones. Small boys also are likely to do more harm than good by destroying the wrong birds, but the work might be effectively done by state boards or commissioners, who should hire trained assistants to destroy the birds in their nests."

The food of a large number of our common native birds is discussed in the pages of this publication, but we have said enough to indicate its value to the farmer and gardener and to show the character of the work which the Massachusetts Audubon Society is doing. Not less successful have been its efforts in preventing the use of the feathers of wild birds in female decoration, and every one becoming a member of the society is expected to agree not to purchase or encourage the use of feathers of wild birds for ornamentation. This, however, does not interfere with the use of ostrich plumes, which are now beautifully dyed for the milliner's trade, the feathers of the different species of barnyard fowls, and the plumage of ducks and peacocks.

Audubon societies and clubs should be founded in every city and town to excite interest in birds, and all school children should be taught their habits and value. Clubs and societies desiring speakers on the subject of birds and their protection may obtain names by addressing the Secretary of the Massachusetts Society, Miss Harriet E. Richards, at the Boston Society of Natural History, Boston, from whom the various publications of the society and suggestions and advice can be obtained.

The aims of associations like this and the work of their members are indications of a high order of intelligence and civilization in any community, and such unselfish and patriotic effort deserves the encouragement and assistance of the public.

THE withdrawal from sale and entry of all Government land more valuable for the production of timber than for other purposes was recommended by the Commission appointed by the National Academy of Sciences to study, at the request of the Secretary of the Interior, a forest policy for the United States. The proposition was considered radical by many persons, but now it has been endorsed by the National Irrigation Congress at its recent meeting in Lincoln, Nebraska, which finds that "the perpetuation of the forests of the arid regions is essential to the maintenance of water-supply for irrigation as well as for the supply of timber for industrial needs, and resolves that the President of the United States shall be memorialized, so soon as a proper and adequate form of administration shall be provided, to withdraw from entry and sale under the Act of Congress of March 3d, 1891, all public lands which are of more value for their timber than for agriculture or their minerals." This is particularly interesting, showing as it does a great change of public opinion since the time, still recent, when some of the most influential advocates for Government coöperation in providing irrigation for the west urged that as forests were detrimental to the flow of streams they should be destroyed. It seems to show, too, that the real opposition to a conservative national forest policy comes from the great corporations who derive large profits from plundering the Government and from their paid attorneys in Congress, and confirms our own observations that a large majority of the people living in the western states and territories are anxious for the preservation of the national forests and opposed to the selfishness of the mining and timber-cutting companies. Unfortunately, however, the opponents of greed and depredation are not as well organized as the plunderers, and they are without proper representation in Washington. Public opinion, however, is gradually changing on the subject of forests in the west as well as in the east, and the time will come when the present era of wanton forest destruction will be regarded as one of the serious blots upon the intelligence and foresight of the American people.

#### Notes on Cultivated Conifers.—IV.

IN the last number of these notes we described those Junipers of the section *Oxycedrus* which can be grown in northern gardens. More important than these are the species included in the section *Sabina*, distinguished by the scale-like crowded leaves closely appressed and adnate to mature branches, while on seedling plants and frequently on vigorous shoots they are elongated, sharp-pointed, free and more or less spreading. To this section belong all the large and valuable species of both hemispheres and a few good garden plants, although most of these Junipers are natives of hot, dry regions and cannot bear the humidity of the Atlantic states. Eight, at least, of these arborescent Junipers inhabit the United States, and, with one exception, they belong to the west and south-west and to regions of scanty rainfall and long, hot, dry summers, and wherever Junipers of this section grow, except in eastern North America, Bermuda, the West Indian and Atlantic islands, and in Sikkim, the rainfall is unequally distributed and the soil is rocky and sterile.

One of the largest and most valuable of the entire genus, however, *Juniperus Virginiana*, which is a native of the eastern United States, is one of the handsomest and most desirable coniferous trees which can be cultivated in this climate. Common from Nova Scotia to southern Florida and central Texas, and from the shores of the Atlantic to the valley of the Missouri River, the Red Cedar, as this tree

is universally called, assumes many forms under the various conditions of its surroundings. In the valley of the Red River in Texas and Arkansas it is sometimes a hundred feet high, with a tall straight trunk three or four feet in diameter; usually it is much smaller, however, and generally forty or fifty feet in height. Sometimes, especially during its early years, the slender branches are pressed close against the stem from the base upward and form a narrow pyramidal head, which in time usually broadens out and finally becomes round-topped and very irregular. This pyramidal form is especially common in the valley of the Hudson River and in some parts of New Jersey and eastern Pennsylvania; in New England, after the first twenty or thirty years, when the Red Cedar is nearly always pyramidal, the stems often become naked below and the head a broad-based pyramid of slender branches spreading below nearly horizontally and ascending above; and in the swamps of Florida, where this tree is common and grows to a large size, the branches are long and often pendulous. The foliage of the Red Cedar is dark yellow-green, or often pale glaucous, becoming bronze-colored at the north during cold weather, and in autumn and winter, when birds do not eat them, the branches are loaded with the small berries, which are covered with a handsome whitish bloom.

*Juniperus Virginiana* has usually been considered to cross the continent to the shores of Puget Sound and Vancouver Island, and to be pretty widely distributed through the interior Rocky Mountain region from the northern border of the United States to northern New Mexico and Arizona. After having seen, however, a good deal of this western tree during the past two seasons, I am inclined to believe that the so-called western Red Cedar as it grows in Wyoming, Montana and Colorado, at least, and perhaps everywhere, will have to be considered another species, and should this supposition prove correct on further investigation, I should propose the name of *Juniperus scopulorum* for it. The habit of the Rocky Mountain tree is very unlike that of any form of the eastern Red Cedar, as may be seen in our illustration on page 423 of this issue, which represents a tree near the Mammoth Hot Springs in the Yellowstone National Park, where this Juniper is very common, and the only arborescent species, and where it grows on gravelly slopes at elevations of six or seven thousand feet with *Pinus flexilis*. It has the slender branchlets and opposite leaves in pairs of the eastern tree, but the fruit is larger, and does not ripen until the second year, while that of our Red Cedar ripens during its first autumn. The branches are stouter and covered with more scaly bark, and the bark of the trunk, which is often forked near the ground, is unlike that of the eastern tree, which separates into thin narrow scales fringed on the margins, but, like that of some other western Junipers, divides into irregular, narrow, connected flat ridges, which break up on the surface more or less freely into persistent shreddy scales. The wood has the same fragrance as that of the eastern tree, although it is rather less powerful, and the color is a duller red. The habit and the character of the bark may be due, perhaps, to differences of soil and climate, which might also affect the color of the wood, and the only really tangible character by which the western tree can be separated from the eastern is the biennial fruit. The fact, moreover, is significant that unless the eastern and western trees come together in north-western Nebraska, the meeting place of the eastern and western floras, they are separated by a continuous belt of country through the middle of the continent several hundred miles wide; and moreover, with the exception of *Juniperus communis*, which encircles the northern hemisphere, and the White Spruce, which crosses this continent far northward and reaches the Pacific coast within the Arctic Circle, no coniferous tree grows in both eastern and western North America. But before the question of the distribution of the Red Cedar can be satisfactorily determined more observations should be made on the time of ripening of the fruit,

especially in Colorado, Utah, New Mexico and Arizona, in the valley of the Columbia River and on Vancouver Island, for it is, of course, possible, although hardly probable, that the proposed *Juniperus scopulorum* may be confined to the northern Rocky Mountains and that *Juniperus Virginiana* really reaches the southern part of that range and even the Pacific coast.

So much has been said in the columns of this journal about the value of *Juniperus Virginiana* as an ornamental tree that it seems unnecessary to say more on the subject. Certainly no other hardy conifer can be used here so successfully to produce the effects which are obtained in countries of milder climates by the employment of the fastigate Cypress of southern Europe, and no other tree is more formal in one of its forms and more picturesque in another. None of our trees are better suited to cover a rocky knoll, or, mingled with trees of less formal outline, to give interest and variety to the landscape.

The Red Cedar, although usually regarded as a slow-growing plant, increases rapidly with generous treatment; it is easily transplanted while young from upland pastures or from the borders of fields and roadsides, where birds industriously sow the seeds, and with care plants ten or twelve feet high can be safely transplanted, although an idea prevails in this country that the Red Cedar is difficult to move and unsuited for cultivation.

Many varieties of the Red Cedar are found in gardens, nurserymen propagating them by means of cuttings. Most of these, however, are hardly distinct enough to warrant attention, the only conspicuous varieties being those with glaucous foliage (var. *glauca*), one with pendulous branches descending along the stem (var. *pendula*) and one of the best of all the weeping conifers, a dwarf form (var. *globosa*), and forms with leaves more or less disfigured by yellow or white markings. *Juniperus Virginiana gracilis*, usually known in English gardens as the Bedford Juniper, is distinguished by slender, somewhat pendulous branches and bright green foliage; it is a plant of somewhat doubtful origin, and may have come from Florida, as it is tender even in England. If it has been tried in our northern gardens, it probably has not survived in them.

*Juniperus Chinensis*, which is occasionally found in our gardens and is perfectly hardy as far north as eastern Massachusetts, is in every way inferior as an ornamental plant to the native Red Cedar which it somewhat resembles, and at the end of a few years usually becomes ragged and shabby in appearance. But this species is interesting, however, in the difference of the foliage of the staminate and pistillate plants, at least while young. On the male plant, which has usually erect much-divided branches, the leaves are usually in threes, acicular, rigid, spreading, and bright green or glaucous, while on the female plant, which has longer and often pendulous branches, the leaves are scale-like, closely appressed, opposite in pairs, and glaucous-green; the two forms, however, are frequently found on the same individual, and on old trees in Japan the leaves are all scale-like and rather glaucous. *Juniperus Chinensis* is widely distributed in eastern Asia, from the borders of Thibet to Japan, where it does not appear to be generally scattered, although it is common on the high volcanic ridges at the base of Asama-yama in central Hondo; here it becomes a shrubby tree thirty or forty feet high, with straggling contorted branches and gray-green leaves. Two venerable and picturesque specimens, seventy or eighty feet high, with hollow trunks some six feet in diameter, before the temple of Zenkōji, in Nagano, show that this Juniper sometimes attains a large size. In gardens there are forms of *Juniperus Chinensis* with bright yellow and with white marked foliage; these are slow-growing and rather delicate plants of no particular value or interest. Another form, usually known in gardens as *Juniperus Japonica*, is in early life a compact bushy plant with many erect branches and acicular blue-green leaves. This shrub, which is probably a product of Japanese horticulture, as it is often cultivated in Japanese gardens, is perfectly hardy and very

distinct in appearance from other Junipers; retaining for several years its peculiar compact juvenile habit, it too often becomes thin and ragged before it is a dozen feet high and loses its value as an ornamental plant. There are varieties of this form in which the young branches with their leaves are yellow or white. This is, perhaps, one of the most difficult of all conifers to transplant.

By many recent authors the so-called *Juniperus Japonica*, which does not appear to be known in a wild state, has been confounded with the prostrate littoral Juniper of Japan and Corea (*Juniperus procumbens*, Siebold.—*Juniperus Chinensis procumbens*, Endlicher), now usually considered a variety of *Juniperus Chinensis*, although perhaps it will, when better known, be found distinct enough to be given a specific position. This seashore plant forms dense mats on low grassy bluffs fully exposed to ocean gales, sending out for long distances its prostrate creeping stems clothed with bright green scale-like leaves. From seeds gathered near the Aino village of Horobetsu, on the coast of Yezo, a number of plants have been raised in the Arnold Arboretum, but it is too soon to speak of their hardiness.

Another prostrate Juniper (*Juniperus Sabina*, var. *procumbens*) is an excellent garden plant with wide-spreading stems which hug the ground and are clothed with bright green foliage. This is now usually considered an American variety of *Juniperus Sabina*, which is an erect shrub or small bushy tree, occasionally twelve or fifteen feet tall, and is widely scattered through central and southern Europe and Siberia. If it has ever been properly tried in our gardens it has probably not proved hardy. The American plant is distributed from southern Maine to the shores of Hudson Bay, and westward in British America from Newfoundland to the Rocky Mountains of southern Alberta, and through northern New England and New York along the shores of the Great Lakes to northern Minnesota and over the mountain ranges as far as the eastern slopes of the Rocky Mountains in Montana. This is the hardiest and most beautiful of all the prostrate Junipers which can be grown in our gardens, where it might well be seen much more frequently than it is.

The prostrate form of the Himalayan *Juniperus recurva* (var. *squamata*) is a favorite garden plant in Europe, and has frequently been planted in this country. In Massachusetts it is not very hardy, although it can be made to grow in sheltered shady positions; near New York and southward it is, however, perfectly hardy. *Juniperus recurva*, which is widely distributed from Afghanistan to Sikkim and Bootan, is sometimes tree-like, but at high elevations remains shrubby and covers large areas with long decumbent stems running on or just below the surface of the ground and sending up numerous short erect branches.

Considering the number of species and forms of *Juniperus* and the attention which has been given in other countries to preserving all its abnormal forms, the genus has contributed comparatively little to our gardens, and as an ornamental tree for eastern America no other species or variety compares with our native *Juniperus Virginiana*.

C. S. S.

### The St. Croix River.—I.

MAINE AND NEW BRUNSWICK.

IT is a far cry from the western St. Croix River to the St. Croix River on the eastern boundary of the United States, but there is a kindred beauty in the forests which border them.\* The same flowers bloom near them, the dancing foliage of Birches and Rowan, the stern symmetry of Fir and Spruce are similar in both. But there is a quieter stateliness about the Maine river as it opens out into the broad bay of Passamaquoddy, with its myriad islands, and a more majestic flow in its tide, which rises to unusual height from the influence of the Bay of Fundy. There is,

\* See Dalles of the St. Croix, Wisconsin and Minnesota (GARDEN AND FOREST, vol. x., page 330).

too, a richness of red color in its beaches and rocks, which gives the landscape a depth of tone rare in a northern latitude, while the clear atmosphere lends sharpness to outlines and affords a wide perspective. The scene is most beautiful when the soft autumn hazes slightly veil the lofty hills and enhance the mystery of the blue distance. When mingled, as it too often is, with the smoke of burning forests, this haze adds a purple tint to the headlands like the enchanted mantle Vesuvius spreads over the jagged lava crests which encircle the Bay of Naples. To one who sails up and down the river the differing views rival each other in charm. Descending, there is seen the gradual widening of the stream and an increasing dignity in the bluffs which rise on either hand; returning at evening up the slowly narrowing channel, the heads of the high hills are violet against a golden sky. Though there are other scenes more rugged and wildly picturesque, few exceed this in noble, tranquil charm.

Some years ago forest fires and the devastation of lumbermen had left the banks of the St. Croix stripped and desolate, and had thrown into mournful relief their rocky sterile fields and hillsides. Now gentle Nature has re-clothed the dreary wastes. The Devil's Head is green with a young and vigorous growth, above which rise here and there to a great height the gaunt skeletons of burned Pines which show how tall the virgin forest once was. This gradual reforestation of the burnt lands of Maine and New Brunswick is very apparent along the railway from Bangor which leads to the headwaters of the St. Croix. Where ten years ago there was but a blackened waste countless numbers of Ashes, Maples, Birches, Moosewoods, Larches, Hemlocks and White Pines are now springing up, interspersed with stiff young Spruces and Firs. The wet lands and scorched moors are hidden by Blueberry-bushes and Alders, and everywhere the red berries of the Dwarf Cornel glow amid their whorls of foliage. Behind St. Stephen, New Brunswick, are piled high ridges of hills, from which one has a wide view over the broad desolate landscape now fast recurring to woodland. To the eye accustomed to the rounded outline of clumps and masses of trees, the serrated edges of the Firs and Spruces climbing up and down the hills seem strange and harsh. The Balsam Firs (*Abies balsamea*) send their top shoots into the air, and sometimes for two or three yards their branches are so short and widely separated that they are almost as unlike trees as the telegraph poles. The groves of Spruce (*Picea rubra*) are sombre and funereal. The bluer, pale, glaucous hues of the White Spruce (*P. alba*) here and there give a brighter tone to the clearly massed ranks of evergreens, or the Hackmatacks (*Larix laricina*) interweave the dark warp with a woof of feathery lightness. Hemlocks (*Tsuga Canadensis*) abound, and their graceful forms and delicate foliage make them the queens of the forest wherever they appear. Where the sun can reach them, on the hillsides and on the edges of the swamps, wave the serrated leaflets of the Mountain Ash (*Pyrus Americana*), whose tops at this season are gay with shining bunches of scarlet berries.

All these trees are found in profusion on the banks of the St. Croix, many of them growing apparently from the heart of the solid rock. Along the sheer banks of the cliffs which rise directly from the salt tide, I saw blocks of stone cleft by the pressure of the strong roots as if by the tools of a quarryman, lying in square masses where they had been hurled down the slope by the force of the vigorous shoots. What these trees live on, beside the rain from heaven, is always a mystery, but they are undaunted by the hard conditions of climate and soil, and though they grow very slowly they still live and thrive where no one would believe a living thing could find sustenance.

Salmon Falls, a mile above the head of navigation of the St. Croix, were beautiful within my memory, and along the banks of the river at the point where they roar and tumble over the rocks into the basin below, I well remember the conical bark wigwams of the Passamaquoddy Indians which

I used to wonder at in my youth. A remnant of the tribe still haunts the old grounds, but their homes are no longer picturesque. Tumble-down old sawmills vex the course of the stream, and their refuse and sawdust form little islands on which tall bushes, and even trees, grow freely. At Calais the tide rises twenty-five feet, and when it falls leaves but a narrow channel between wide stretches of mud-flats, so that the river's beauty ebbs and flows periodically for a mile or two. But lower down, the pebbly or sandy beaches of vivid red which alternate with the high bluffs of differing shapes, are always fine, even when the tide has receded to its utmost limit.

This river was discovered and named by the French, under Pierre du Guast Sieur de Monts, in 1604. The name Ste. Croix was then given to it on account of the two branching arms made by the mouths of two rivers visible from the little island on which the small garrison established itself and built a fort and houses, which one finds rudely portrayed in *Champlain's Voyages*. One of the arms on the British side is now known as Oak Bay, and into it flows the River Warweig, from the valley of which rises a curious group of round, heavily wooded hills, clustered together in a way that suggests some extraordinary convulsion of Nature, or a Titanic game of bowls, with the balls left deserted in a huddled mass. From the lofty ridge in New Brunswick, which overlooks this singular scene, the view is remarkably beautiful. Landward, great moor-like stretches dotted with woods reach away in every direction to a far-distant horizon line, broken here and there by faint purple hills, and directly below one's feet are seen lying the round or conical dark hills, clustered together and often actually rising from the waves. Over the tops of them in the shadowy distance are visible the blue waters and the far-away shores of the myriad islands of Passamaquoddy Bay. Just above St. Andrews, New Brunswick, the highest mountain of all, Chamcook, lifts a bare red top from a fringe of encircling woods. Its old red sandstone formation shows this hill to have been one of the early upheavals on the continent, and although it is not five hundred feet high, nothing grows upon its summit. From it one has a comprehensive view of all the surrounding region on both sides of the St. Croix, dotted with myriad lakes, and can behold the broad bay with its hundreds of islands of varying extent.

### London Letter.

MISCANTHUS.—We have in cultivation at least three, possibly four, of the six or seven known species of this genus. They are better known under the name of Eulalia, now sunk under *Miscanthus*, a near ally of the Sugar-cane, *Saccharum*. These ornamental plants are useful in the mixed border or as isolated specimens on the lawn. The oldest species cultivated in gardens, *Miscanthus Japonicus*, is now represented by three distinct forms. The type has culms six or eight feet high and three-eighths of an inch in diameter; these are clothed with elegantly curved leaves three feet long and about an inch wide, glabrous above, hairy beneath, the sheaths also hairy, the midrib white, the other portions bright green. In the autumn they bear terminal erect panicles of purplish flowers like those of the Sugar-cane or the male plumes of the Indian Corn. The variety *Zebrina* has leaves like the type, with the addition of broad, irregular, transverse bands of yellow. The third form, called *Japonicus variegatus*, is a plant of especial beauty. Its culms are six feet high and a quarter of an inch in diameter; the leaves are from two to two and a half feet long and from half an inch to an inch wide, glabrous both in blade and sheath, the former green with a central stripe of white and broad marginal bands of creamy yellow. I suspect this is another species, and not a form of *M. Japonicus*, but it has not yet flowered. According to Walters, who collected *M. Japonicus* in Formosa

in 1882, it is grown by the Chinese for fuel and thatching, and is a large stout Reed. *M. Sinensis* is distinguished by its shorter, thinner culms, which at Kew attain a height of five feet and are less than a quarter of an inch in diameter, while the leaves are two and a half feet long, a quarter of an inch wide, channeled their whole length and shining green, with a white stripe along the midrib. The sheath is glabrous and covered with a wax-like bloom, and there is a tuft of long silky hairs on each side of the ligule. This species is a native of China and Japan. It was introduced by the French horticulturists in 1889 under the name of

and other parts of China. Planted in strong deep soil, where they will get plenty of moisture and sunshine, these plants are seen at their best and show to advantage in comparison with those grown under less liberal treatment.

*PHRAGMITIS COMMUNIS VARIEGATA*.—This is a highly decorative variety of the common Reed, the *Arundo Phragmitis* of Linnæus. A small plant of it was presented to Kew four years ago by Messrs. Wallace & Co., of Colchester, and it is now a mass of stems ten feet through and six feet high, clothed with leaves a foot long, an inch wide, and green, striped and margined with creamy white, the sheaths

Fig. 54.—Juniper in Yellowstone National Park.—See page 420.

*Eulalia gracillima*, var. *foliis univittatis*. Under the name of *M. Ogi* we have a third species which was introduced from Yokohama in 1895. It is as hardy as the others, larger than they are, and at least as handsome. In the Bamboo garden at Kew it has formed a cluster of about fifty stems nine feet high and half an inch in diameter, the leaves three feet long, one and a half inches wide, and dark green, with a white stripe along the midrib, the sheaths glabrous and tinged with purple, the ligule bearded. It promises to be a plant of exceptional value in the garden. The specific name looks like Chinese or Japanese vernacular. Possibly it is *M. sacchariflorus*, a native of Peking

partly rose-purple, partly green, and the band round the ligule black-purple. It is by far the most ornamental form of this Reed known to me, and it is an ideal plant for the water-side. It was, I believe, found by Dr. Wallace as a sport from the type, which is common in wet places in this country, and he took it into his garden and found the variegation was permanent. Possibly the stems would grow to a height of eight or ten feet in a warmer situation than the margin of the lake at Kew. It must not be confused with the Gardener's Garters, *Phalaris arundinacea*.

*LAPORTEA CANADENSIS*.—I lately saw a large quantity of this plant under cultivation in the Jardin d'Acclimatation,

Paris, and on inquiry I was told by Monsieur Patry, the superintendent of those exceedingly well managed gardens, that it was being distributed to the French colonies as a silk-fibre plant, and that in this respect it is superior to the China Grass, *Bœhmeria nivea*, and to Ramie, *B. tenacissima*. It has been found to grow more freely and to be less difficult to manipulate than either of these two plants, which, according to Monsieur Patry, have consequently been abandoned in its favor by the French planters. I see that this species is a common weed in various parts of North America, and that its fibre has been utilized for textile purposes. In the *Treasury of Botany* it is stated that *L. Canadensis* is a native of the Alleghany Mountains and that "it has lately (1884) been imported into Germany as a new textile plant; it is perennial and capable of enduring the climate of central Germany, but further experiments are needed ere its commercial value can be determined." In view of the fact that these silk-fibre plants are exciting considerable attention among manufacturers, and of the belief in France that this *Laportea* is better than either of the *Bœhmerias*, it would be worth while for some one in America to investigate its properties. Very little appears to be known about it in England, where fibre plants of all kinds have received considerable attention in recent years.

**TIGRIDIAS.**—What are the natural conditions under which *Tigridia Pavonia* grows in Mexico? Cultivators generally treat this and the other species of *Tigridia* as plants that require a comparatively dry situation. In the gardens of the Earl of Ilchester, at Abbotsbury, however, *T. Pavonia* is grown in a swamp and it thrives amazingly, growing to a height of three feet, the leaves large, healthy and lustrous, and the flowers almost as large again as one usually sees them. It has been in this position several years and has increased rapidly. Possibly this is a case in which the cultivator is more kind to the plant than Nature can afford to be. An instance of this character is *Begonia Socotrana*, which Nature grows in dry hot sand; in the hands of the cultivator this plant is happiest, that is, it grows at least three times as large and bears enormous crops of flowers, when planted in strong loam, freely watered and kept in a hot, moist stove. Another such case is *Stapelia gigantea*, the largest flowered of all the carrion plants. At Kew it is grown in a stove with *Crotons*, *Dracænas*, etc., where it blooms freely, and it is now coming into flower. On seeing our plants a few days ago a Cape botanist exclaimed that this method of cultivation would kill the plant. But, in a house where succulents are grown at Kew, it grew indifferently and never flowered. By the way, cultivators of *Stapelias*, plants which often fail to grow, may like to know that altogether the best method I have tried is to plunge the pots containing them during the summer in cinder-ashes in a frame facing south, where, in warm weather, the lights are taken off. The Kew collection has improved astonishingly under this treatment.

**HOW NEW PEAS ARE RAISED.**—The history of garden vegetables is a subject of absorbing interest. Darwin devoted much attention to them in his *Animals and Plants under Domestication*, a work which, I venture to think, present-day horticulturists might study with advantage. In the course of a lecture by Mr. A. W. Sutton, of Reading, on the progress in vegetable cultivation during the last sixty years, it was stated that a seedling Pea is now generally the result of so much interbreeding that many distinct types will be represented in the ultimate cross. This cross will give a pod containing from six to ten or more seeds, and it is at this point that the work of the hybridist ceases, and that of the selector commences. When sown these seeds will in all probability produce as many distinct seedling Peas, some partaking of the character of the parents and some not. Seed saved from each of these frequently varies in each case to such an extent that the greatest patience is required in order to secure any fixed type at all. Some will be tall, some dwarf; some early, others later; some large podded, some small; some pale green in color, some dark; some curved in the pod, some straight; some pointed at the end and

some square; and last, but not least, some may be round-seeded and some wrinkled. The selector must therefore begin again, and starting from the most promising plant in each row, endeavor to build up a seedling plant which will reproduce itself from seeds without variation, a task often extending over many years. While the garden Pea has been enormously improved during the last sixty years, *Ne Plus Ultra*, raised fifty years ago, is still, perhaps, the best of all tall late marrow-fat Peas. Another popular favorite now is *Veitch's Perfection*, introduced in 1859. American Wonder, introduced by Messrs. Sutton in 1881, is still more extensively grown than any other dwarf wrinkled pea. Mr. Sutton also stated that in order to make their Pea trials comprehensive enough to determine the value of new seedlings, and to test older varieties offered, they find it necessary to sow from 600 to 700 rows annually.

### Notes from Baden-Baden.

**SCABIOSA CAUCASICA** is one of our hardiest perennials in all soils and positions, and it produces its beautiful pale blue flowers throughout summer and autumn. A variety called *Connata* or *Elegans* has larger petals, and is altogether a more robust plant. There is also a white variety, but this is more delicate than the type and capricious as to soil and treatment. I have worked constantly for many years on *S. Caucasica connata*, sowing and selecting the best varieties, even though the variation was slight. This season I have been successful in getting a plant with bright deep ultramarine flowers, and another with pure white flowers. The latter is very robust and much more valuable than the typical white-flowered form.

*Incarvillea variabilis* has been in flower since June, and is a plant well worth growing. It is half-shrubby, making a round bush three feet high and of the same diameter. The main stem branches into many divisions, the ends of the branchlets bearing the flowers, which are bright purple and about the size of those of a florist's *Pentstemon*. The leaves are bright green and deeply cut. It is quite hardy and flowers the first year from seed.

Among *Kniphofias*, a new species, *K. Tysoni*, has flowered here; it is a large stately plant, with rather short bluish green leaves at least five inches broad and two feet long. The flowers, although not gaudy, are bright brick-red, changing to white.

*Crocus pulchellus* was in great beauty some time ago, with soft purple flowers, faintly striped. At this time, October 10th, *C. Marathonisus* is showy, its pure white flowers being brightened by a few orange blotches and the broad orange pistils. *Polygonum sphærostachyum* still throws up its handsome spikelets dressed in bright aniline-red.

Baden-Baden.

Max Leichtlin.

### Ornamental Grass Beds.

IT is rather puzzling to know why so many *Coleus*, *Alternantheras* and annuals are used in our public gardens and parks year after year when there are many other plants of as easy cultivation and much more pleasing. Beds of *Coleus* are little more than patches of gaudy color, with which one is quickly satiated. In this locality there are beds planted permanently with Grasses; these are made to look different each year by introducing various species of moderately tall flowering and foliage plants. In planting with Grasses the tall Reed, *Arundo donax*, is given the central position; next in height is *Erianthus Ravennæ*, and the varieties of *Eulalia Japonica* with *Arundo donax variegata* come next. *Eulalia univittata* follows in this order, and if smaller Grasses are needed, some of the variegated *Arundinarias*, *Pennisetum longistylum*, *Elymus glaucus* and *Festuca glauca*, the last-named being quite a dwarf variety. All of these Grasses are hardy here, and the plants should be placed far enough apart so that there will be no necessity to change them for several seasons.

If it is desired to use only Grasses and allied plants we have *Cyperus Papyrus*, which grows next in height to *Erianthus Ravennæ*. The color of this *Cyperus* is a rich dark green, unlike that of any other Grass. The purple form of the Sugar-cane, *Saccharum officinarum*, var. *violaceum*, can be depended on to grow at least five feet in a single season and form a neat bushy plant. *Cyperus alternifolius* attains a height of from three to four feet, and *Pampas Grasses* from two to four feet,

according to the variety. The lemon-scented Grass, *Andropogon citratus*, soon makes a dense growth several feet in diameter and two feet high. All of these tender plants, with the exception of the *Cyperus Papyrus*, are kept over winter in a half-dormant condition. The *Cyperus* should be kept moving, but only one or two plants need be taken indoors when there is sufficient accommodation for propagating it. The best method is to put some growths with the roots shortened back into the damp sand of a warm propagating-house; they will put out strong working roots in a few days. If potted and kept growing in soil which contains a good quantity of chopped sphagnum-moss, the plants will form grassy growths which should be torn apart and treated in the same way as the parent pieces. From one plant at the start several hundred may thus be had by planting-out time.

If flowering-plants are desired for use with the Grasses the large-flowered *Cannas* are pleasing. These are becoming so abundant in variety that several of the old kinds are almost lost sight of. The old *C. Ehmannii* is unsurpassed for rich leaves and flowers; the large flowers are in nodding spikes, with little or none of the seedy appearance common to most of the newer varieties. This variety grows from four to six feet high. While the common kinds keep well over winter when dried off, *C. Ehmannii* is best wintered when kept slightly moving. *Hibiscus coccineus*, a noble herbaceous species from the southern states, thoroughly hardy here, and probably so in most places if a little protection be given to the roots, should head the list of the most desirable tall-growing herbaceous plants. Specimens with single stems will grow to a height of about eight feet; by stopping the growths early in the season low and bushy plants may be had. The flowers are bright scarlet, larger than those of the forms of the shrubby *H. rosa-sinensis*. The leaves are five-parted on long stalks. Altogether this is one of the best plants to use with the Grasses. In places where it is not hardy, the roots being thick and of a succulent nature, they may be treated similarly to those of the *Dahlia*. For dark foliage plants we have *Black Beauty Canna* from two to four feet in height, and *Strobilanthes Dyerianus*, from one to two feet high.

Botanic Garden, Washington, D. C.

G. W. Oliver.

[It is usually a mistake to grow the various Grass species closely together either in masses or lines, as is too often the practice. The charm of these plants consists mostly in the beauty of form found in the graceful lines of their leaves and stems. While many individual species of Grasses are handsome, hardly any two compose well in garden borders, unless, possibly, when it is desired to clothe the ground with a low-growing Grass or with a *Carex*, under some of the nobler species. But otherwise each species should stand in isolation, for, aside from preventing confusion of form, there are no plants whose lower parts require less masking than the Grasses, Sedges and Bamboos. Even the tall *Cyperus pungens*, which has smooth round stems six or seven feet high, and only a crown of leaves at the top, is much more effective unmasked, and one certainly would not give *Papyrus Antiquorum* a near neighbor to hide its sturdy stems. In fact, the same may be said of all the nobler or smaller Grasses, tender or hardy, and no plants will better repay thoughtful care in the selection of their location in the garden.—ED.]

### Grafted Stock for Roses.

LATELY I have had frequent opportunity for noting the advantages of using grafted stock for Tea and other Roses. The favorable conditions under which Roses have been grown in this country, and the facility and cheapness with which they can be propagated from cuttings have placed grafted plants at a disadvantage. The grafted plants must be bought in most cases, owing to lack of skill and facilities for preparing the stock. Shrewd growers, with the Old World instinct, have never lost sight of the advantages of grafted stock, and the superior quality of the flowers grown by them has led to an increase in the number of grafted plants. Clear practical instructions for working the plants have been given in *The American Florist* by Mr. Robert Simpson. Grafted plants of *American Beauty* show by their increased vigor just how much of the bed is planted with them, and this is true of Tea Roses. The stock exercises an invigorating influence. Perhaps the most notable success has been with grafted plants of Mrs. Pierpont Morgan. Mr. Montgomery, of the Waban Rose Conservatories, thinks they owe their comparative freedom from the dreaded eel-worm to the continuous use of grafted stock,

and cuttings from these plants are less liable to this pest. Only the *Manetti* is recommended for stock for Tea Roses. It is itself much of a perpetual, and on this account is preferred to all others. The *Banksian* has been tried; this is too rank, the plants become soft, and produce poorly-colored flowers, although it is an excellent stock for climbing Roses. The *Brier Rose* follows its natural bent, going to rest in winter.

Grafted plants differ in appearance from Roses grown on their own roots; the dark velvety leaves are more plentiful, and the long stems, which usually come only from the base on plants on their own roots, break from any part of the grafted plant. Where solid benches are used, grafted plants are of further advantage, as with a little trimming the plants can be carried over two or three seasons, a practice rarely possible with plants on their own roots.

Wellesley, Mass.

T. D. Hatfield.

[The points in favor of grafted Rose stock have been strongly stated recently in horticultural journals in this country, but it has yet to be satisfactorily demonstrated that grafted stock produces any better results in the long run in America.—ED.]

## Correspondence.

### Garden Annuals from the Plant-breeder's Standpoint.

To the Editor of GARDEN AND FOREST:

Sir,—Early in 1897, Professor L. H. Bailey sent to the seed firm which he thought catalogued the greatest number of annuals an order for a packet of seeds of every kind of garden annual, hardy and tender. About six hundred different sorts have been growing at Cornell this year, and I have been looking over the whole field from the plant-breeder's point of view. I dare say no one ever goes to a botanic garden and looks for a business opportunity in plant-breeding, as one might investigate any other commercial opening. Doubtless a man gets a reputation for pedigree Pansy seed because he loves Pansies and must grow them for his own pleasure and profit. Cross fertilizing is essentially an enthusiast's work and no one can be hired to be enthusiastic. Then, too, there is greater success to be won in working with popular favorites than in trying to introduce new plants, just as more kinds of Grapes are needed, rather than new kinds of Juneberries. Nevertheless, there are certain results which can be obtained only from comparative study of collections that are as complete as it is possible to make them.

I have made a list of the twenty-four most popular kinds of garden annuals. Half of these I have listed as old-fashioned, and the other half as the popular favorites at this time. Balsams (*Impatiens*), African Marigolds (*Tagetes*), Moss Roses (*Portulaca*), Stocks (*Mathiola*), Candytuft (*Iberis*) and Godetias are all old-fashioned flowers and are likely to be always cherished, though their greatest popularity is probably past. Their horticultural evolution seems to be finished. We have found out their limitations, and they have been so well developed that one may purchase just what is desired in the way of color, form and habit much as one would purchase manufactured commodities. The next six kinds of flowers were perhaps equally popular once, but are now neglected in the reaction against formality and artificial coloring. These are *Datura*, *Prince's Feather* (*Amaranthus*), *Cockscomb* (*Celosia*), *Ageratum*, *Clarkia*, and the summer *Chrysanthemums*. They also seem less versatile than the six first named. Their limitations are naturally closer and the named horticultural varieties are not so numerous. *Prince's Feather* had a general use in gardens, but the species of *Amaranthus*, which are cultivated for their foliage, are, nowadays, with the *Ageratums*, chiefly employed for the special purpose of making beds and borders. Even if the natural school were not in the ascendant, with its restricted and isolated use of flowerbeds, I should feel compelled to exclude bedding plants from the present discussion. Their value is determined by a set of characters (behavior under the shears) which is unimportant in the case of the home garden.

Of the twelve kinds on this list of present favorites all, I think, are by nature entitled to permanent prosperity, and six at least are versatile to the point of bewilderment. Pansies, Poppies, Sweet Peas, China Asters, *Phlox* and the various species of *Dianthus* represent six entirely independent and non-competing types of beauty. Like and dislike, however, are matters of personal liberty, and from the present standpoint I shall try to leave out the element of beauty. Aside, then, from individual preference for one type of beauty, certain ideals of garden cultivation seem to be most nearly realized

by *Phlox Drummondii*. The varieties of *Phlox* are compact and neat in habit, have no untidiness of foliage after blooming, are hardy, easy of cultivation, prolific, continue flowering over a long season, and are lasting as cut flowers. The range of color is wide. In form *Phlox* presents little variation, the typical and the cuspidate being, perhaps, the two kinds commonly recognized. Sweet Peas, which have most of these traits of a popular garden favorite, with the added charm of fragrance, can consistently be placed in this list, although I exclude the Morning Glory and all other climbers, because Sweet Peas are much cultivated in the garden proper, while the fitting place for the Morning Glory is about the house. China Asters would be almost ideal if they were earlier. The general grower has neither time nor money to prolong their season by indoor starting and successive sowings. Whether the species has been pushed to its limits of earliness or not I cannot say. It is said that the China Aster is essentially a cool-weather plant. Of Pansies, Poppies and the Pink or *Dianthus* tribe I shall not try to define the limitations, and I hope they will never lack for appreciation, selection and education. The other half of the present list contains six kinds of plants with narrower limitations, and consequently less versatility, judged by the number of advertised named varieties. The California Poppies (*Eschscholtzia*) have a narrower range of color than the common Poppies, and I fear it is impossible to get them to speak through the glorious reds. Verbenas have about the same range of colors as the *Phlox Drummondii*, with little variation in form and a less desirable habit for ease of cultivation, but the advantage of fragrance. Petunias are also somewhat awkward to care for; their smell and touch are unpleasant to some, and fixation of character can never be as perfectly attained as in the other groups mentioned; and in the case of the double forms hand fertilizing is necessary. Coreopsis and the Corn-flowers have still narrower limitations, but I believe they are among the twelve favorite garden annuals to-day. Most persons will be content if these are not much changed. It is difficult to see any benefit to be derived from crossing three such distinct types as Corn-flowers, Sweet Sultans and *Centaurea Americana*, all of which belong to the same genus. Mignonette, with its special uses and the narrowest limitations of the twelve, completes my naming of the twelve garden annuals most popular at present. The lovers of Dwarf Nasturtiums, Gaillardias, Calendulas, Cosmos, Sunflower and Zinnia will think these deserve a place among the best twelve. I should include them in a list of eighteen.

I do not mean to say that this list of twelve contains the best annuals, but merely those most popular. They are not the twelve which are indispensable for my own garden. I also believe that this list excludes two that are most promising to the plant-breeder. Cosmos is comparatively new to the east, and we do not know its limitations, but all agree that it has great possibilities. The great need with Cosmos is the hastening of its blooming time. Zinnia, once a general favorite, but now neglected, has, I am sure, great possibilities. It must probably always have a deep flower, but it need not be stiff and formal. If the Japanese or the Chinese had had Zinnias to work with all these centuries we should now have some fanciful forms. The Zinnia and the Dahlia were not known outside of Mexico until this century. The tropical climate, it is said, is not suited to double forms, and people of the tropics are not garden lovers. The double Zinnias and Dahlias were among the most consummate expressions of the florist's art at a time when artificial flowers were the craze to the exclusion of forms that are loose, irregular and free. The color range of Zinnias is very wide, and of the yellow series, while China Asters have the blue. Zinnias are earlier than China Asters, and their profusion of bloom, lasting qualities and ease of cultivation are nearly ideal. Nobody wants them for cut flowers, but that is because stiff and formal flowers are out of fashion. Can new forms and new informality be bred into the Zinnias? I believe so. Plant-breeders are experimenting with Dahlias, and both Dahlias and Zinnias have much in common with the varied China Asters and fanciful Japanese *Chrysanthemums*.

Ithaca, N. Y.

Wilhelm Miller.

## The Forest.

### The Forest Reservations of Southern California.

AMONG the forest reservations set aside by executive orders of President Harrison and President Cleveland are three of great importance to southern California. These reservations are known as San Gabriel, San Bernardino and San Jacinto, and aggregate more than two million acres. The smallest is that of San Gabriel, the most westerly. The San

Bernardino and the San Jacinto reservations, each of 737,280 acres, are about ninety miles from the ocean, on the slopes of the Sierras, which separate the fertile cultivated valleys of southern California from the Mojave and Colorado deserts. The longest slopes are toward these valleys, and are traversed by the numerous mountain streams which supply the whole section with water for irrigation and domestic purposes. From the bases of the mountains on the north and east stretch away broken, undulating and barren desert wastes, watered only by infrequent springs and wells.

The San Bernardino and San Jacinto reservations are almost continuous, being separated by the narrow pass of San Gorgonio. Together they form a large and immensely valuable forest reserve, which includes the three highest mountains in southern California, San Bernardino, San Gorgonio (sometimes called Grayback) and San Jacinto. San Gorgonio is the highest of the three, about 11,500 feet, but they are all noble and imposing. On San Bernardino and San Jacinto there is a sparse growth of timber nearly to the summit, but the timber line of San Gorgonio is several thousand feet below the summit, and the gray appearance of its barren crest, covered with masses of broken rock, has given it its popular name. Late in September of the present year I saw on the northern slope of San Gorgonio scattered patches of snow, the remnants of last winter's falling, and a day or two later its summit was whitened by the first light snow of the coming winter season.

The forests of these mountains do not compare in extent and majesty with those of northern California and of Oregon. From the lumberman's point of view they are insignificant, and, at a little distance, the transient tourist who views them only from the south and west, sees no forests worth mentioning and goes away with the impression that the slopes of the mountains are all barren. But when the cañons and the valleys are penetrated that lie between the successive ranges, especially in the north and east, forests are found that are certainly beautiful, if not of great commercial value. At intervals there are stretches where the Pines have crowded out all other trees, and one may ride for miles unimpeded by underbrush among their huge and towering trunks. But most of the forests are composite, principally made up of Pines, Firs, Balsams, Spruces, Larches and deciduous and Live Oaks. The streams are bordered by Willows and Alders. Occasionally a puny Maple is seen, very unlike the handsome Maples of the east, and the Bay-tree flourishes at certain altitudes. The forests of this region are between the altitudes of 4,000 and 8,000 feet.

In places the Chapparal is dense, made up of Manzanita, Buckthorn, wild Mahogany, the Madroña, Greasewood, etc. Some of these bushes are covered with long, silvery, frond-like blossoms or, as the Manzanita, for example, with red or scarlet berries. Holly and Mistletoe are frequently found, and many gay flowers, such as the Golden rod, Clematis and the bright blossoms of various species of Cactus. Where there is moisture there are many varieties of Ferns.

These mountains were formerly overrun with animal life, but the too-ready rifle of the hunter has changed this condition. Grizzly and cinnamon bears and wild cats are still found occasionally in the deepest recesses. Deer are comparatively plentiful and hundreds are shot every season. Gray squirrels abound, although they are by no means as numerous as in former years. Brown squirrels and chipmunks, too insignificant to tempt even the most wanton marksman, are abundant. The streams are full of trout and are kept replenished from year to year from state hatcheries. The same variety, the California brook trout, in the waters of the only lake of this region, grows to enormous size. This lake also affords fine duck-shooting in the winter. The mountain quail, larger and handsomer than the quail of the valleys, is found in numbers. Doves are also plentiful. Among birds not fit for food are blue jays, woodpeckers, owls, hawks and condors. Of reptiles the rattlesnake is the only one of importance. Theoretically this venomous creature is a terror to many, who for this reason are unwilling to enter these regions. Practically, one may ride for days without seeing a single specimen, and the instances of injury from its bite are rare indeed.

A resort known as Seven Oaks is the centre of one of the most beautiful of the park-like districts among these mountains. This is a collection of tent-houses and log-cabins where hospitality is open-hearted and without ostentation, and where good company and good cheer may always be found. Here one may rest and study Nature or may plan and execute a great variety of fishing, hunting and camping excursions. The most convenient route to reach Seven Oaks is by wagon twelve miles from Redlands to a point near the western base of Mount San Bernardino. Thence a mountain trail, nine miles through

the forest, takes the traveler to his destination under the northern base of the same mountain. It is difficult to understand, without actual experience, how completely this day's ride isolates one from the busy workaday world.

On every hand mountains rim the valley in which Seven Oaks lies, with a distance of, perhaps, twenty miles in each direction from ridge to ridge. The Santa Ana River, the most important stream in this section of southern California, traverses the valley from east to west, finding its sources at the greatest elevations and fed by smaller tributary streams. From the heights above these waters one may look down, toward the east, upon the wide stretches of the deserts, broken by ranges of low hills with great variety of color and topography.

The Santa Ana curves to the northern side of this valley and between it and the heights of San Bernardino and Grayback, on the south and south-east, are wooded benches where one may ride for hours in the shade of beautiful trees. Bridle-paths, or trails, traverse them in different directions. Wherever there is moisture from springs or streams, mountain meadows or cienegas are found, and herds of cattle are pastured on these. In spring and summer the grass is abundant and luxuriant. The slopes on the northern side of this valley are less heavily wooded than on the south. On surmounting them the range could be crossed into another valley of less extent and at a higher elevation, about 6,000 feet above the sea, and here would be found Bear Valley Lake, a storage reservoir for irrigation purposes. Its outlet is Bear Creek, which rushes away to a junction with the Santa Ana, and the two, united, sweep on their course to the Orange-groves of southern California, their waters keeping the finest of these in health and productivity. These valleys are among the most important, and are typical, in their general characteristics, of a series which extends from the ocean to the south-eastern slopes of San Jacinto, in a semicircular sweep of more than a hundred miles.

There are no mills for sawing lumber in this immediate vicinity, although there are a few farther westward. There are some mines, but most or all of these are on the desert-side of the range. Here and there a pioneer had acquired title to a bit of arable ground, with an appurtenant water-right, before these lands were set aside as a forest reservation, and some portions had been granted to railroads. All of these vested interests will, of course, have to be protected or adjusted in whatever regulations may be made for preserving these forests, but no intelligent man who has studied the subject at all could hesitate for an instant in his opinion as to the absolute necessity for preserving them. They shelter the sources of the waters upon which depend the prosperity of all of southern California. The orchards which they keep alive are worth not less than thirty-five millions of dollars, which is three times the amount invested in mines in southern California. Irrigation will depend more and more upon storage reservoirs, for the limits of available water-supply under the present system of use are already in sight. If these mountain valleys were denuded of their forests the winter rains would rush down their precipitous slopes in torrents, which would soon overflow the storage reservoirs, and there would be little or no flow of summer waters. Under such conditions Orange-growing in southern California would be a most hazardous occupation, if not impossible.

The deadliest foes to these forests have been not the miners, or even the lumbermen, but the sheep-herders and careless campers in whose wake came devastating forest fires. The sheep have now been driven away and the campers have seemingly been educated or frightened into greater care. It is certain that forest fires have been less frequent during the past summer than formerly. Appreciable efforts are being made to enforce the laws governing these reserves, and are effecting good results.

A new and important interest which will be useful in preserving these forests is that of the companies now being formed and some of them at work, for establishing plants to generate electricity by the fall of the same waters which furnish irrigation. Some of these plants will each be capable of developing as high as 10,000 horse power, which will be utilized in Los Angeles and at intermediate points for purposes of lighting, manufactures and transportation. These interests will be valuable and will help on the rapid development of southern California. But they, even more than irrigation, will demand a continuous supply of water which must not fall below a certain minimum. This flow must be maintained throughout the long dry summers, and every effort will be made to secure the volume of water and to lessen loss from evaporation by expensive systems of tunnels cut through the

solid rock. These are very fascinating projects, and so feasible that they will doubtless rapidly be pushed to completion. Thus private interests may accomplish more in the end than the fear of the law or Government patrol toward maintaining the integrity of these reservations.

But roads will be needed in order that these plants may be constructed and maintained. By these roads these unique mountain nooks will be rendered accessible to the multitude, and their charm of isolation and primitive grandeur will be at an end. When the multitude comes into the forests the mountaineer, to whom they have been sacred, and by whom they have been loved, will have no other refuge than the desert. Progress, which is the greatest good to the greatest number, is destructive of romance and of the refined pleasures of the few to whom Nature in her lonely and rugged moods is a source of constant pleasure. Comparatively few Californians know their own mountains well. They dwell within sight of them, year after year, ignorant of the beauties which so abundantly repay the slight efforts and sacrifices involved in exploring them.

## Recent Publications.

*Life Histories of American Insects.* By Clarence Moores Weed. Illustrated. The Macmillan Company, London and New York. 1897.

In this, his latest book, the author seeks to give in an interesting, readable, untechnical way some account of the transformations and short lives of a few of our common or most conspicuous insects, chiefly those to be found in the northern or middle portions of this country. The book is divided into twenty-six chapters, each one of which treats of some particular species of insect, or a species and its nearest allies, the last two chapters being devoted to true spiders and so-called "harvest spiders." No attempt is made to give a complete history of any species, nor is any claim made to entire originality, although many of the observations are no doubt the result of Professor Weed's own careful studies. In a pleasing, brief, instructive way some of the salient facts in the life history of the insect are touched upon, the end of each short chapter leaving much unsaid that might be told, but giving the reader a desire for more information, and perhaps leading him to the still more pleasant and profitable task of personal investigation. The range of subjects is well chosen to illustrate types or modes of life in the insect world, although wood-borers and some others which come under common observation or speculation are not referred to. A chapter or two each given to water lovers, earth-burrowers, leaf-eaters, leaf-miners, case-bearers, predaceous insects, those which are parasitic, etc., are sufficient to give the tyro a good idea of some of the things he should see in the insect life about him and which too commonly pass unnoticed. It would add greatly to the cause of economic entomology and to the proper understanding of our insect friends and foes if such books as Professor Weed's were more commonly read, for such reading must inevitably lead any thoughtful mind to further study or the desire for it. The chapter on "Sand-wasps and their Victims" must open the eyes of many readers to episodes in insect life occurring commonly about them, facts familiar to entomologists, but scarcely known except by students of that branch of natural science. Much might be quoted here, but such quotations would give but a slight idea of the many interesting observations on insect life presented in an attractive and popular form in this volume.

This book might well be used as a reader in connection with the science-teaching in some of our schools. The pages are abundantly illustrated with original or more familiar figures borrowed from other works; and it is pleasing to add that proper credit is always given to other authors or publishers for any observations or figures which have been borrowed.

## Notes.

A market garden at Gretna, Louisiana, managed by a Chinese company, is briefly described in *The Rural New-Yorker*. Besides Cow Peas, used on old land, a fluid obtained from decom-

posed fish is depended on to fertilize the soil. In the intensive system of cultivation practiced a cupful of this ill-smelling fluid is poured at the root of each plant. Only the Chinese trade is supplied, and the chief vegetables grown are Pumpkins, Okra, Yams, Cabbage and several members of the Cucumber tribe.

It appears from a note printed in the October issue of *The Kew Bulletin of Miscellaneous Information* that the so-called bandoline wood is derived from *Machilus Thunbergii*, a relative of our Sassafras-tree. The shavings and chips of the wood when soaked in cold water yield a viscid mucilage-like matter which is used by Chinese ladies in bandolining their hair. This tree is a native of southern Japan, Formosa and south-eastern China, and is an exceedingly handsome evergreen with elongated leathery lustrous leaves.

The crop of chestnuts is disappointing in quantity this season owing to dry weather in August, when the nuts should fill out rapidly. Sound chestnuts of ordinary size from nearby northern states sell for twenty cents a pound in this city. This shortage is particularly evident in the lack of offerings by Italian vendors on the sidewalks. Hickory-nuts are abundant, and the best shell-barks sell for ten cents a quart. Black walnuts are not yet in market. Butternuts, from Vermont, sell for twenty-five cents a half-peck in their hulls.

In the first issue of *The Plant World*, a monthly journal of popular botany, Dr. F. H. Knowlton, the editor, calls attention to the existence in a swamp near Laurel, Prince George's County, Maryland, of a form of *Lilium superbum* with stems seven or eight feet tall and clear lemon-yellow flowers without spots, but with large bright green triangular markings at the base of the perianth-segments. The leaves are described as similar to those of the common form, although perhaps more scattered, and the flowers are similar in size and shape. Although not abundant, it appears that this plant has been known locally for many years and that a few specimens can be found every year.

A writer in the October issue of *Forest Leaves* describes two White Pine-trees on the farm of Miss Gallagher, in Allegheny township, Cambria County, Pennsylvania, which are believed to be the two largest trees in the state. The trunk of one of these trees is oval shaped, the longer diameter being over eleven feet and the shorter nearly seven feet. About twenty feet from the ground the trunk divides into a dozen branches, the principal one being about thirty inches in diameter and ninety feet high. The smaller tree is seven feet in diameter. A finger-board which formerly stood on the road from Cresson to Loretto at a side road two miles from Cresson bore the legend "This way to the Big Trees."

From a recent number of the *Pharmaceutical Journal* it appears that in November, 1895, an ordinance was promulgated in Corea legalizing the export of Ginseng. For centuries red Ginseng has been sent to Pekin by the overland embassy, the trade being a royal monopoly from which the King of Corea derived the principal portion of his revenue, the export by sea being prohibited. The annual crop is limited in quantity to about 15,000 catties, upon which an excise duty of \$10 a catty is charged under the new regulations, to which is added an import duty of five per cent ad valorem, levied on its arrival at a treaty port in China. Under the new law the King is compensated for his loss of the Ginseng monopoly by an equivalent addition to the privy purse.

In his enthusiasm over the beauty of the form of *Apera arundinacea*, in last week's issue of GARDEN AND FOREST, Mr. Watson did not fully describe the coloring of this handsome Pheasant Grass. The common name is aptly given for its browns and reddish browns, distinctive of the attractive bird, and perhaps no other Grass is so quaintly and highly colored. T. Smith, of Newry, Ireland, introduced this species some years ago, but it seems to have only lately attracted attention. It is one of the handsomest Grasses. While hardy, it seems to require care in removal or transplanting, and springtime appears to be the proper season for planting out. Like all the noble Grasses, this should be grown as an isolated specimen, or, at least, separate from other Grasses.

A writer in a recent number of *La Semaine Horticole* estimates the possible length of life of a number of European trees, basing his calculations on many measurements. Such estimates are, of course, interesting, although the length of life of any tree depends so much on conditions of soil and on immunity from accidents that they must be taken with many allowances. The following are his estimates: Judas-tree (*Cercis Siliquastrum*), 300 years; Elm (*Ulmus campestris*), 335; Ivy (*Hedera helix*), 450; Field Maple (*Acer campestre*),

516; Birch (*Betula alba*), 576; Orange (*Citrus Aurantium*), 630; Cypress (*Cupressus sempervirens*), 800; Walnut (*Juglans regia*), 900; Plane (*Platanus orientalis*), 1,000; Linden, 1,100; Norway Spruce, 1,200; Oak (*Quercus Robur*), 1,500; Cedar of Lebanon (*Cedrus Libani*), 2,000; and Yew (*Taxus baccata*), 3,200 years, while to our Southern or Bald Cypress (*Taxodium*) a length of life of 3,000 years is ascribed.

One of the most delightful American trees in autumn is certainly the Sassafras when it becomes conspicuous in the landscape by the varied tints of the delicate orange coloring of its leaves, and this year it has been unusually beautiful. But it is not in autumn alone that the Sassafras is attractive and interesting; in winter its bright green, lustrous branches make a cheerful note on the margin of the forest; in spring it is charming, with its drooping clusters of delicate yellow flowers surrounded by the enlarged and showy scales of the expanding buds; all summer long its variously shaped fragrant leaves retain their healthy luxuriance; and the fruit, which birds rarely allow to remain long on the branches, is showy, with deep blue berries and much thickened and scarlet cups. Few people plant the Sassafras, perhaps because it is a native tree, and nurserymen rarely offer it for sale. Large plants are difficult to transplant, as the thick, fleshy roots are scantily provided with rootlets, but small plants which can often be found in abundance along fence-rows and wood borders, are easily managed and grow rapidly when set in good soil. With many other common American trees the Sassafras ought to be often planted in American parks and along the margins of American highways.

Of the exotic trees recently introduced into American gardens one of the most promising is the Japanese *Prunus Pseudo-cerasus*, which has for several years proved hardy in the Arnold Arboretum, where it is growing rapidly and has not yet been attacked by insects or fungal diseases. Forms of this tree or of some allied species with double flowers are now rather common garden plants in the United States and Europe, but these are less hardy and of much slower growth than the wild type which appears to be rare in American collections. It is the largest tree of the Rose family in Japan and, next to the Apricot, more cultivated for its flowers by the Japanese than any other tree. In the forests of Yezo, where it is very common and sometimes eighty feet high with a trunk three feet in diameter, it resembles in the appearance of the bark and in habit the wild type of *Prunus Cerasus*, the Cherry-tree of our gardens, and it might be mistaken for that species. In autumn it is particularly beautiful, as the leaves turn deep scarlet and light up the forest before the Maples assume their brightest colors. For centuries this Cherry has been used in Japanese gardens and temple grounds, and near Tôkyô there is a Cherry avenue more than a mile in length along the banks of the Sumi-da-gawa, and at Koganei ten thousand of these trees were planted a century and a half ago in an avenue several miles long. It is a valuable timber-tree in Japan, and, if it proves unattractive to insects in this country, it may prove useful here in forest as well as in ornamental plantations.

Our London correspondent, Mr. William Watson, publishes in a recent issue of *The Gardeners' Chronicle* some interesting notes on the creeping species of *Ficus* now in cultivation. They are *F. radicans* of gardens, although that name has been given by Roxburgh to another plant; *F. stipulata*, popularly known as *F. repens*, with a smaller-leaved form known as *F. minima*; *F. falcata* and *F. barbata*. *F. radicans* is a useful evergreen for covering walls, pillars, etc., in warm houses. There is a variety variegata with leaves marbled and margined with white. *F. stipulata*, or *repens*, is the plant commonly found in American hot-houses. It is a native of Japan and China, and has been cultivated in Europe for a hundred and twenty-five years. This climbing Fig is hardy in the southern states and in California, and in countries of such temperate climates is one of the most useful of all evergreens for covering walls or the sides of buildings. *F. falcata*, which has recently been introduced into English gardens by Low & Company, is a native of the Malayan Peninsula and Archipelago, where it is not uncommon on trees and rocks. By Dr. King, the author of the classical monograph of the Asiatic species of *Ficus*, it is described as "a very remarkable and beautiful species, varying much in fruit and in the shape of the leaves, even in the same plant, the leaves on its small branchlets from the lower part of the main stem being often much smaller than those from branchlets near the apex, and occasionally different in form." *F. barbata*, which is a native also of Malaya, is a more vigorous plant, with hairy leaves often six inches in length, and is occasionally cultivated in European hot-houses to cover Palm-stems and pillars.

## Autumn Work among the Trees.

NOW is the time at the north to prepare for planting trees next spring, for all planting north of the latitude of this city is most safely done at that time of the year. Further south the long autumn enables trees planted when the leaves are ripe to push out new roots and establish themselves before the ground freezes. Where cold weather follows close after the early frosts a tree planted in the autumn has no opportunity to develop new roots and, therefore, loses not only the benefit it would have obtained in a more temperate climate in an early and vigorous spring growth, but is forced to go through the winter without the aid of roots in actual working condition. Trees planted in cold countries at this season of the year do not necessarily die, but they are more apt to suffer than those planted in the spring; they are often blown over unless carefully staked, and they are frequently upheaved by the frost or thrown out of the ground entirely. For all operations, however, connected with the planting and care of trees, except the mere setting in the ground, the autumn is the best time. At this season planting plans should be made and stock selected, and the ground should be made ready to receive the trees as soon as the frost leaves it in the spring. Spring in this latitude is so short and the rush of spring work is so pressing that it is impossible to properly prepare ground for planting unless it is done during the previous summer or autumn. This is the time, therefore, when northern planters should decide what trees they want to use next spring and where they will plant them; it is the time to select and order nursery stock, and here it may be said that better results are always obtained by personal inspection and selection by the purchaser than by leaving it to the seller to fill his orders. If the planter has facilities for protecting plants through the winter in a cold cellar or pit, it is better to obtain them now than in the spring, when nurserymen are crowded with orders and too busy to devote proper time and attention to digging and packing their trees. The ground being prepared, the exact position of each plant determined on and the plants on hand, the mere operation of setting them in the ground takes but a short time. A man, moreover, who is thus

prepared beforehand for spring planting can take advantage of the first suitable weather and get his trees into the ground as soon as the frost is out and it is dry enough to work, while if he waits for material ordered in the spring it will frequently not be received until after the trees have started to grow and warm dry weather has set in. In a climate like that of our northern states, where summer follows hard after winter and where spring is almost unknown, there is no other operation of the farm or garden which demands more carefully planned preparation than tree-planting.

It is wise economy, too often neglected in this country, to prepare the ground thoroughly before trees are planted. Where isolated specimens are required ample pits should be dug for them, and the larger they are made the better it will be for the health and beauty of the future trees. A hole three feet deep and twenty feet across is not too spacious for a long-lived tree of the first class. Into these excavations the loam taken from them should be returned, together with enough peat or good soil added and thoroughly mixed with it to supply the place of the poor subsoil, hard pan and stones, which should be rejected. If it is proposed to plant trees closely over considerable areas, as is sometimes necessary in large parks, the ground should be thoroughly subsoil-plowed and broken up, the large stones removed and the surface as carefully mellowed and enriched with good stable-manure, as if it was proposed to raise a crop of corn on the land. When the land is prepared in this way the surface can be easily stirred and kept free of weeds by horse power until the trees are large enough to shade the ground.

But the care of growing trees is quite as essential as the planting of new ones. As we have often insisted, time and labor are worse than wasted in planting unless the after care is intelligent, determined and ceaseless. Now is the best time for pruning trees, before work among them is rendered unpleasant and unsafe by extreme weather and before their limbs are coated with ice, and every year all young plantations intended to produce ornamental effects should be looked over; too vigorous or unnecessary branches should be checked and all but single leaders removed, that forks of the main stem which are liable to endanger the trees in the future by splitting may be prevented.

This is the best season, too, for studying plantations and marking for removal all trees which are injuring their more valuable neighbors. No tree can attain its full size or its noblest expression, or hope for a reasonable period of longevity, unless it can obtain its share of air, sunshine and food. Many of our public parks and private gardens are disfigured by trees which are left dwarfed or starved, or forced out of shape by aggressive neighbors. Most planters desire to produce an immediate effect with their work, but planting for immediate effect means overcrowding, and when the young trees begin to struggle with each other for mastery, delay in thinning is fatal, for they will begin at once to spindle up or bend toward the light and will soon be ruined as ornamental trees.

These autumn days can be used to no better purpose, therefore, by one who has trees or hopes to have them than by a thorough study of his ground before the snow covers it; by thorough preparation for getting through spring planting without hurry, and by a resolute and determined use of the axe wherever the thinning of trees is necessary to improve the appearance and insure the permanency of his plantations.

## Notes on Cultivated Conifers.—V.

THE genus *Cupressus*, which is distinguished by monocious terminal flowers and subglobose woody cones with scales abruptly dilated, and flattened and furnished at the apex with short central knobs, is widely scattered over the Atlantic and Pacific coast regions of the United States, Mexico and Lower California, and in the Old World

is distributed from south-eastern Europe and the Levant along the Himalayas to China. The seventeen or eighteen species now recognized can be conveniently grouped into two sections—*Eucupressus*, distinguished by its four-sided branchlets, denticulate leaves, and large fruit maturing at the end of the second season, with numerous seeds in several rows under each scale; and *Chamæcyparis*, distinguished by flattened, often deciduous branchlets, entire leaves, and small fruit maturing at the end of the first season, with from one to four seeds under each scale. The genus has made important contributions to gardens, and nearly all its members are handsome and fast-growing trees. To *Eucupressus* belong the Monterey Cypress (*C. macrocarpa*), one of the most picturesque trees of the American forests and the most universally planted conifer in our Pacific states, *C. sempervirens*, in its fastigate form, a chief ornament of gardens in the countries bordering the Mediterranean, the so-called Cedar of Goa (*C. Lusitânica*), a native of India and for more than two hundred and fifty years an inhabitant of Portugal, where it has become naturalized, and the Funereal Cypress of the Chinese (*C. funebris*), a frequent inhabitant of temple gardens and a living monument over many Chinese graves. No *Eucupressus*, however, is hardy in our northern gardens, and in these notes only species of *Chamæcyparis* need be considered. These all grow comparatively near the sea in Atlantic and Pacific North America and in Japan, only five species being known.

The type of this section, *Cupressus thyoides*, is the familiar White Cedar of the eastern states, where it grows in cold swamps on the Atlantic and Gulf coast plain, usually immersed during several months of the year, from southern Maine to northern Florida and the valley of Pearl River, Mississippi, covering them at the north with pure forests of wide extent, and at the south mingling with the Bald Cypress and other moisture-loving species. It is a slender pyramidal fragrant tree often seventy or eighty feet tall, with a stem rarely more than two feet in diameter, thin, spreading branches clothed with open flat fan-shaped spray, and dark, dull blue-green foliage, becoming rusty brown at the north in winter when exposed to the sun. The White Cedar, which is rarely cultivated in our gardens for the reason, perhaps, that it is a common native tree, is, of course, perfectly hardy; and in thoroughly drained or in undrained soil grows rapidly into a slender, shapely, graceful open pyramid. European nurserymen propagate several forms of this tree with glaucous and with yellow-marked foliage, and others with fastigate and pendulous branches. *Cupressus thyoides* Hoveyii is a slender form with short ultimate branchlets forming dense terminal tufts. *Cupressus thyoides* nana is a dwarf compact form with glaucous foliage. The small dense pyramidal bush with erectly spreading glaucous leaves, which turn bronze color or purplish brown during the winter, is now usually supposed to be a monstrous form of the White Cedar; its origin, however, is unknown, and by different authors it has been called a *Cupressus*, a *Juniperus*, a *Retinospora*, a *Frenela* and a *Widdringtonia*. This curious little plant, which possesses little beauty, was much used a few years ago in European gardens and is frequently seen in American collections, although it is not always perfectly hardy in the neighborhood of Boston.

Two species of *Chamæcyparis* (*Cupressus Nootkatensis* and *C. Lawsoniana*) inhabit Pacific North America and are among the noblest and most valuable trees of this continent. The more northern of the two, *C. Nootkatensis*, the Sitka or Yellow Cedar, is a common inhabitant of south-eastern Alaska, where it is scattered through the forests of Spruces and Hemlocks which cover the coast mountains, and ranges southward through western British Columbia and Washington to the valley of the Santiam River, in Oregon. It is the most valuable timber-tree of Alaska, where it sometimes grows to the height of one hundred and twenty feet, with a trunk six feet in diameter. Its light, close-grained pale yellow wood has no superior in our

forests as material for the cabinetmaker, and in its lasting quality when put into the ground. The slender branches of the Yellow Cedar, sweeping outward and upward in long curves and furnished with long, gracefully drooping frond-like bright yellow-green branchlets, make this tree lovely in its native forests; but to develop all its beauties it requires the humid climate of the north-west coast, and in drier regions displays little of the grace and vigor which make it one of the handsomest of our conifers. In gardens, both in the United States and Europe, the Yellow Cedar is usually known as *Thuopsis borealis*, and is still generally seen only in juvenile form with dense pyramidal habit and blue-green foliage. It appears to be quite hardy from New York southward, but east of Cape Cod, although it can often be kept alive for some time, it usually succumbs at the end of a few years to the hardships of its surroundings, and is never really satisfactory in this part of the country. *Cupressus Nootkatensis* is no exception to the rule, that the plants of this group show a marked tendency to seminal variation, and European nurserymen propagate a number of more or less well-marked forms with variegated and glaucous foliage and with pendulous or abbreviated branches. None of them, however, has much morphological interest or horticultural value.

The largest of all the Cypress tribe and one of the great timber-trees of the world, *Cupressus Lawsoniana*, is now a familiar ornament in the parks and gardens of all temperate countries, although it is less than fifty years since its discovery. Its great size, for specimens two hundred feet in height, with trunks ten or twelve feet in diameter, are not rare, the remarkable thickness of its deeply lobed bark, surpassing in this all other members of the Cypress tribe, its graceful beauty in youth, with its delicate feathery branches and drooping leading shoots, and the nobility of its port at maturity, give exceptional interest to this tree. Restricted in distribution to a narrow strip of the southern Oregon and northern California coast, with outlying stations on the headwaters of the Sacramento River, Lawson's Cypress has shown itself capable of supporting very different conditions from those in which it flourishes naturally; and from New York southward it may be seen in a fairly vigorous condition, although it never, perhaps, grows as luxuriantly in the Atlantic states as in western Europe. In New England, unfortunately, it merely survives in sheltered positions, and we shall have to give up the idea of using this tree here in general planting. The tendency of Lawson's Cypress to seminal variation is remarkable, and more than sixty varieties have been named by European nurserymen. One of the most distinct of them, *Cupressus Lawsoniana erecta viridis*, is a strictly pyramidal plant with bright green foliage, which appeared many years ago in the Knapp Hill Nursery, at Woking, in England, and is one of the best of the pyramidal conifers. Other seminal forms are distinguished by pendulous branches, by dwarf habit and by more or less variegated or abnormally colored foliage, but in many of these varieties the divergence from the type is so slight that their names are not worth preserving. Named in honor of Sir Charles Lawson, of Edinburgh, the distinguished rural economist and for many years the head of the nursery firm of Peter Lawson & Son, this tree is universally known in the forests of Oregon and the lumber-yards of San Francisco as the Port Orford Cedar, from the harbor on the Oregon coast, where the lumber is largely shipped to San Francisco. The wood is light, hard and strong, and abounds in a fragrant resin, which makes it exceedingly durable. For many years it has been used in large quantities in California for the interior finish of houses and in boat-building, and from this wood the matches used on the Pacific coast are made.

The *Retinoporas* now familiar to the cultivators of coniferous plants all belong to this section of *Cupressus*, and are all forms of two Japanese trees, *Cupressus obtusa* and *C. picifera*, although some of them appear so distinct that it is sometimes hard to realize until the appearance of a normal branch discloses the secret of their origin, that they

are merely monstrosities that have been cherished and propagated, perhaps, for centuries by the Japanese.

*Cupressus obtusa*, the Hi-no-ki of Japan, is a native of the southern mountain provinces and the most valuable timber-tree of the empire. Sacred to the disciples of the Shinto faith, it is planted in the neighborhood of all Shinto temples, which are built of its wood. It is also cultivated for its timber in the mountain forests of central Japan, where it often attains the height of 100 feet, with a tall straight trunk three feet in diameter near the ground and free of branches for fifty or sixty feet. The wood is light, strong, tough and very durable in contact with the soil, pleasantly fragrant like that of the other species of this section, and white, straw-color or pink. The palaces of the Mikado in Kiôto were made from the wood of this tree, which also serves for the frames of Buddhist temples and the interior finish of expensive houses. In Japan *Cupressus obtusa* is one of the favorite subjects for dwarfing, and is often cut into eccentric shapes, and several abnormal varieties or juvenile forms are cultivated. *Cupressus obtusa aurea gracilis* is a free-growing and beautiful form of this tree introduced into our gardens a few years ago by the Veitchs; and there are dwarf bushy forms in cultivation in this country and Europe, some with leaves of normal color and others with yellow foliage. These are highly prized in Japan, and can be seen in almost every Japanese garden. A distinct form known as *Retinospora lycopodioides* has stout erect branchlets densely clothed with bluntly awl-shaped, very dark green leaves, and another, *Retinospora filicoides*, is peculiar in its long, slender, spreading branches covered with short, broad, light green sprays of quadrangular branchlets.

*Cupressus picifera*, the Sawara of the Japanese, is planted in their forests and temple-grounds with *Cupressus obtusa*, and produces redder, coarser-grained and less valuable wood. The common Golden *Retinospora*, *Retinospora picifera aurea*, is a form of this tree, and is here, perhaps, the most frequently cultivated of the Japanese *Retinosporas*. A more remarkable form is the so-called *Retinospora squarrosa*, in which all the leaves are disposed in decussate pairs and are short, acicular, pale blue-green and spreading or slightly bend toward the branchlets. This is a low, broad, dense bush or small tree with large divided and forked stems. Almost as remarkable is *Retinospora filifera*, another form of this tree with long, slender, pendulous, thread-like branchlets clothed with subulate, acute, dark green leaves arranged in remote alternate pairs; there is a yellow-colored form of this plant. This is certainly one of the most remarkable of all pendulous-branched conifers, but, unfortunately, it is very capricious, sometimes flourishing with great luxuriance, as in Mr. Hunnewell's pinetum at Wellesley, Massachusetts, but more often perishing from the cold of severe winters.

For the north-eastern states, at least, the introduction of the Japanese *Retinosporas* has proved a doubtful blessing. The most beautiful and valuable of them, *Cupressus obtusa*, appears quite hardy, and in its early years makes a handsome plant here, but it soon develops a tendency to grow thin, and well-furnished specimens more than twenty feet high are not common. *Cupressus picifera* is a more rapid-growing, and perhaps a hardier, plant here, but with its loose narrow crown of more upright branches it is less ornamental than the Hi-no-ki. Some of the varieties are morphologically interesting and some of them are handsome; they are uncertain, however, sometimes flourishing for years, and then dying suddenly or gradually becoming thin in foliage and shabby in appearance; and where they do flourish, unless used with caution, they bring too many strange forms and unnatural colors to our plantations.

All the plants of this group can be readily propagated from cuttings, which root easily and grow rapidly; and to bring out all their beauties they require rich well-drained soil, and in this climate partially shaded situations protected from the drying winds of early spring.

In the next numbers of these notes we shall discuss the

horticultural value of the remaining genera of Cupressineæ, *Thuya*, *Thuyopsis* and *Libocedrus* and the Taxodineæ, which give to our gardens *Sciadopitys*, *Sequoia*, *Cryptomeria* and *Taxodium*.

## The St. Croix River.—II.

MAINE AND NEW BRUNSWICK.

NO Oaks are visible near the St. Croix River, though the name Oak Bay indicates that they were once found here; but a few miles inland a rare specimen is now and then seen beside a lonely lake, afar from its kindred and having quite the air of an exotic. They apparently do not sow themselves, for two trees on Boyden's Lake are the only ones I ever saw anywhere near the shores of the river. The fierce winds and driving storms render tree-moving a thankless task, and without great care transplanted Maples and Elms do not thrive, even though natives of the locality, owing to the short summers. Elms planted fifty years ago in the towns of the region are only half as large as they should be after the same length of time in southern Massachusetts. On the other hand, Evergreens flourish, and the White Spruce, which finds lower New England quite too warm for it, grows to majestic proportions, making a good show from the sea in twenty years.

Fields that were quite bare in 1865 are now impenetrable woods in great need of skillful foresting. It is impossible to see the wealth of timber that is likely to go to waste without wishing that there could be some intelligent management of the resources of the country, so that good, well-grown, handsome trees might replace the spindling growths which result from overcrowding. Both the White and Norway Pine abound in this locality, and their commercial value is likely to increase immensely even in a decade, so that if these trees were helped to good smooth growth they might prove of value to their owner more than sufficient to pay the expense of taking suitable care of them. Everywhere, however, one recognizes the danger of fire in the dead underbranches, and in the brushwood rudely cut down along the waysides, and left to dry and ignite from the first cigar stump thrown away by a careless passer-by; for there is no vigilant village improvement society, such as exists at Mount Desert, to use proper preventive measures to avert disasters of this kind.

A lovely feature of the woods along the St. Croix is the prevalence of that exquisite flower, *Linnæa borealis*, whose twin bells greet one with their aromatic fragrance throughout the month of June. This favorite of the great botanist, to which he has given his name, loves the moist mossy shade of the sparse growth along the water's edge, and carpets the ground with its small leaves and perfumed pink flowers. A little later in the season the sheer precipices are hung with Ferns and delicate Harebells, blue and white, which find a secure foothold in clefts and on ledges just out of reach from a boat. Still another ornament of these woods is the Low Cranberry, *Vaccinium Vitis-Idæa*, which makes a foot cloth fit for the dance of Dryads, with its shining dark green leaves rising from a creeping tufted stem, all jeweled with the little red-cheeked berries which nestle among them. In groves that I remember along these salt, wind-swept shores I have often picked up the empty shells of sea urchins, dropped by gulls that fly over the evergreens, which shows how near the trees grow to the home of fishes, and what hard conditions of wind and weather are theirs to struggle with.

The aspect of the St. Croix region is still that of the border settlement. Its navigable length is about thirty miles, and but little of it is occupied. After leaving Eastport, which is a compact little town with houses closely grouped together upon one of the islands of the bay, no village on the American side is visible for eighteen miles. Up the river such dwellings as appear are far apart. St. Andrews, New Brunswick, forms a sort of half-way station, and is the sleepest of provincial towns, feebly galvanized by summer

visitors; yet its situation is very beautiful, with a lofty hill behind it, fine beaches and a breezy invigorating climate. Robbinston, on the American side, once a famous little place for ship-building, has mouldered with the decay of that industry. A few new houses for summer residents, half-buried in trees, are to be seen along the banks of the river, from which there are lovely views, and the walks and drives of the neighborhood are picturesque and interesting.

The active life of the neighborhood settles in the border city, Calais, at the headwaters of the St. Croix. It is connected by a bridge with the New Brunswick city of St. Stephen, and these two are stirring, but slowly-growing places. The two towns together have a population of perhaps fifteen thousand, and besides sawmills at the falls, there is a cotton mill and also a shoe factory. These and other industries bring a rough population, which threatens to replace the more dignified element which first peopled this section of the country.

With a little well-directed and united energy in municipal improvement on the part of its inhabitants Calais might be made a beautiful town, for, owing to the care of the early settlers, the streets were planted with rows of trees which now overshadow them during the summer months. The outlook upon the river is also agreeable. Fences have been removed and many of the grass-plots between the houses and the street are kept neatly mown, but others are sadly neglected. Recently a little park about the Soldiers' Monument, in the centre of the town, has been put in order, and this contains a semicircle of fine old Elms, which make a good background to the armed figure on its pedestal. There is an opportunity for a good open space about the handsome Public Library if some unsightly buildings which disfigure the neighborhood could be removed and the spot they occupy grassed and planted. But the City Council is not endowed with the artistic sense, and the members say the town has only money for what is necessary, and must dispense with ornamental improvements for the present.

It is gratifying to notice among the inhabitants an increasing interest in remedying the long-standing defects of the town, and the efforts of the more tasteful and public-spirited among them will no doubt be imitated as time goes on. The general aspect of the main street is certainly much better than it was ten years ago, and the care of lawns is beginning to be recognized more generally. When the Washington County Railroad is completed, and the inhabitants of eastern Maine no longer have to go through New Brunswick to get home from Boston by land, it is probable that improvements will take a start, and that aesthetic as well as financial progress may be looked for in the Border City.

The natural beauty of the St. Croix should be wisely guarded by those who dwell upon its banks. A stretch of woodland along the river, about three miles below Calais, a small part of which belongs to the city, might be converted into a riverside park of real beauty. The steep banks could be descended by terraced paths so as to reach the beach from the road above, through what is now a tangle of trees and underbrush. There are fine Hemlocks and other evergreens in these groves and plenty of Maples and Canoe Birches, which a little attention would greatly beautify. Vistas opened in the proper places would reveal charming views of the narrows and headlands of the river, and the inhabitants would soon take pride and delight in so valuable a possession if it were only made reasonably accessible. Through the brief summer months the citizens delight in living out-of-doors, and revel in the lovely scenes along the river, which they enjoy from boats and carriages; so some project for a park near at hand might, if skillfully managed, meet with good support, since they have a nucleus to begin with in the piece of woods they own.

Taken as a whole, the St. Croix River is wonderfully beautiful. Its great tides, its broad beaches, its picturesque shores, its red rocks, its sandy coves and bold headlands have a unique character which never fails to impress a stranger,

and they are specially endeared to those to whom they have been from early childhood familiar.

Hingham, Mass.

Mary C. Robbins.

## New or Little-known Plants.

### *Hypericum galioides*.

WE have frequently called attention to the beauty of the shrubby North American species of *Hypericum* and their value as garden plants, and several of them have been first figured on the pages of this journal. They all produce clear yellow flowers at midsummer when comparatively few shrubs are in bloom, and they flower profusely.

One of the most beautiful of the group, *Hypericum galioides*, is figured for the first time on page 433 of this issue, from specimens gathered in the Arnold Arboretum, where it has been successfully cultivated for a number of years, and where it makes a handsome compact broad round bush about three feet in height, with slender stems covered with dark green linear-lanceolate, more or less revolute mucronate crowded leaves an inch and a half long and an eighth of an inch wide, and small axillary and terminal flowers which open at the end of July.

*Hypericum galioides* naturally inhabits wet ground, and is distributed from Delaware to Florida, where broad-leaved forms occur (var. *ambiguum*), and to eastern Tennessee and Georgia.

All the shrubby *Hypericums* can be easily raised from seeds and grow freely in good rich garden soil, and were they better known they would, no doubt, become extremely popular for the decoration of summer gardens.

## Foreign Correspondence.

### London Letter.

ORCHID BREEDING.—A paper on some curiosities in Orchid breeding was read by Mr. C. C. Hurst, an amateur Orchid grower, at the last meeting of the Royal Horticultural Society. Orchids are now receiving so much attention from the hybridizer, and so many surprising crosses have been obtained, that students of evolution will find abundant material among the hybrids and crosses represented in gardens in the Orchid department alone. Too much importance should not be attached to what are termed bigeneric crosses, generic distinctions, especially in this order, being often of the slightest character. A hundred years hence, no doubt, many of the genera of to-day will be known only as synonyms. An analogous case is that of *Pelargoniums*; these plants received special attention from cultivators at the beginning of the present century, and botanists saw no less than twenty genera in what we now know as one, namely, *Pelargonium*. The genus *Aloe* is made to include three other genera by some botanists. A still more striking instance of the artificiality of generic distinctions is that of the botanist who has lately separated the tuberous *Begonias* into a distinct genus, which he has named *Lemoinea*. Mr. Hurst said that hybrids between two distinct species were generally exactly intermediate in character. There are, however, many exceptions to this statement. "There is often a greater or less divergence toward one parent. . . . Many instances can be cited in which the pollen parent has greatly influenced the character of the flower, and the seed parent the vegetative organs of the progeny. On the other hand, the opposite has occurred." (Veitch.) That the same cross may be repeated, and identical results obtained each time where fixed species are used, depends upon the fixity of the species. Mr. Hurst protests against hybrids from the same parents receiving distinctive specific names, however much variation they may show. A list of the hybrids raised with their parentage reveals some extraordinary crosses and shows how little is indicated of what may be termed the blood relationship of species and even of

Fig. 55.—*Hypericum galioides*.—See page 432.

genera, either in characters of size, form or color, or in our nomenclature. While such crosses as *Odontoglossum* with *Phalænopsis*, or *Cypripedium* with *Dendrobium*, are im-

possible, the fact that *Sophranitis* has bred with *Cattleya* and with *Epidendrum*, proves that wide differences in stature and form are not barriers to interbreeding. A good

hybrid Orchid is now worth more than a new introduction ; in other words, collectors value highly the hybrid of artificial origin, and therefore Orchid breeding has come to be a lucrative business. It has also a scientific interest, if only because it throws light upon the relationship of plants. Mr. Hurst pointed out that it was not unusual for Orchids to produce seed-pods and apparently, also, seeds, but the latter may turn out to be chaff. Monsieur Lemoine, of Nancy, who has bred so many fine garden plants other than Orchids, makes a practice of trying to cross almost every plant that flowers with him, and while these are in most cases "fools' experiments," in some the result is successful. Many Orchid growers in England are now making similar experiments, and there is often a keen competition for the possession of a new Orchid or good variety solely for breeding purposes.

DO ORCHIDS DEGENERATE?—This question is now under discussion in English gardening papers ; that is, do they decline in health under cultivation? Every cultivator of experience knows that some do and some do not. There are certain Orchids, I think I may say a large number, which never do become established in our collections. They may last a year or two longer in one garden than in another, but they will not "stay" anywhere. We may now and then discover by accident the secret that leads to success with one or the other of these refractory ones ; generally, however, we must look to the collector to keep up the supply by sending home more plants if we are not to lose them. Luckily, however, we have on the other hand a considerable number of Orchids, which, with ordinary care, flourish for an indefinite time. It has been suggested that the failures are cases of starvation, and chemical analysis of the plants is said to indicate this. Chemical manures are recommended, but how far they may be used with safety is doubtful. Experienced cultivators declare that manure in any form for Orchids is to be avoided.

DENDROBIUM TAURINUM, var. AMBOINENSE.—A plant of this gigantic Dendrobe was shown by Messrs. Veitch & Sons at the last meeting of the Royal Horticultural Society. It had somewhat compressed leafless pseudo-bulbs six feet high, bearing elegant curved racemes a foot long, of flowers with yellow sepals, brown-red petals and lips tinged with purple. Each flower is about two inches across, the segments being strap-shaped and more or less spirally twisted, a character which belongs to several other species from the same region. Messrs. Veitch's plant was brought from Amboyna by Burke, who died recently. The type is a native of the Philippines, where it was found by Cuming ; he sent it to Loddiges, of Hackney, who flowered it fifty years ago. "It is found growing on the Mangrove-trees in the swamps skirting the seashore, where, during severe storms, the plants are sometimes washed by the spray. In such places its pseudo-bulbs often attain a height of ten feet, and produce racemes two feet long" (Veitch). At Chelsea it is grown in a hot, moist stove along with *D. Phalænopsis* and other essentially tropical species. I am afraid its size is against its ever becoming popular, even if it could be obtained in quantity, which from all accounts is extremely unlikely.

CRYPTOPHORANTHUS DAYANUS.—One of the most remarkable of the Orchids belonging to the *Masdevallia* group is this, the largest-flowered of the genus to which it belongs. A plant of it was shown this week by Sir Trevor Lawrence, bearing about two dozen flowers, which in shape and marking are suggestive of a frog's head. They are odd-looking, even for an Orchid, and the curiously windowed sepals must be puzzling to naturalists who try to explain the peculiar structure of flowers. Writing of another species, generally known as *Masdevallia fenestrata*, Darwin, in his *Fertilization of Orchids*, says these windows are intended to admit insects for the purpose of fertilization. But one wonders why the flowers only partially open for this purpose and do not, as in the case of their allies, throw their doors (the sepals) wide open. The habit of *C. Dayanus* is like that of a *Restrepia*, but the leaves are larger

and the short-stalked flowers are about an inch long, pale yellow spotted with purple ; the color of the inside as seen through the windows is buff-yellow. The plant is a native of Colombia and has been known in gardens twenty-five years.

LÆLIA PUIMLA.—I noted in my last letter a form of this plant which had received a first-class certificate under the name of Gatton Park variety. A second plant of it has just flowered in the collection of Messrs. Low & Co., which differs only from the first in having the blotch on the front of the labellum of a deeper purple hue. It was imported among a large batch of the type. For some unaccountable reason the Orchid committee gave this second plant a second-class certificate and renamed it Low's variety.

CÆLOGYNE VEITCHII.—A fine example of this plant was shown this week by Messrs. Veitch & Sons ; it bore six pendulous racemes a foot long of numerous white flowers an inch across. The species was first described in 1895 by Mr. Rolfe from a plant flowered in the Veitchian nurseries, which had been sent from New Guinea by Burke. Dried specimens showed that the racemes are sometimes two feet long. The short column, the absence of markings from the lip and the very short, rather obscure basal keels are quite different from any previously known species. The pseudo-bulbs are fusiform, four inches long and the lanceolate leaves six inches long.

VANDA CÆRULEA.—A white-flowered variety of this noble Vanda is not as beautiful as the type, but it possesses the charm of novelty at any rate. Such a plant was shown this week by Mr. J. Rochford. It bore a spike of flowers which in size and form were medium (there is an exceptional range in these two characters in this Vanda), and although not snow-white the sepals and petals were sufficiently colorless to be called white ; the lip was tinged with dull pink. It received a certificate.

VANDA MOOREI.—This is said to be a natural hybrid between *Vanda cœrulea* and *V. Kimballiana*. It was shown in flower this week by Mr. W. J. Moore, of Bradford, an importer of Orchids from the Shan States, where *V. Kimballiana* is a native. The new plant has broader and more markedly channelled leaves than the last-named species, and the flowers are larger, with broader sepals and petals tinged with lilac, the lip being purple. I do not know if *V. cœrulea* and *V. Kimballiana* are found wild together ; if they are, then possibly *V. Moorei* has originated as suggested. Mr. Rolfe thinks there can be little doubt of its hybrid origin so far as can be ascertained from a comparison between it and its supposed parents.

## Cultural Department.

### Chrysanthemums.

LADY FITZWIGRAM, a very early white Chrysanthemum of recent introduction, bids fair to become one of the best sorts for decorative purposes, either grown in small pots or for cut flowers. It is dwarf, and, as generally grown in sprays, is quite effective. It does not, however, compare in size and substance with later varieties. *Glory of the Pacific* is a superior early pink, also quite dwarf, and an excellent variety for bush specimens. *Midge*, as its name implies, is also dwarf, and well suited for growing in small pots. The flowers are comparatively large, and as they mature the florets become charmingly irregular in their arrangement. Among early yellow-flowered varieties none are superior to *Marion Henderson*. The color is the purest yellow, and the flower, while loose, is full ; the florets become twisted as they mature.

Gradually the season for larger blooms approaches. Among yellow-flowered varieties *H. L. Sunderbruck* is still without a peer in color and size. *Harry Hurrel* is also a flower of deep tone and is compactly built. Among white flowers *Mrs. H. Robinson* is unrivaled in beauty of form and finish. It is compactly incurved, and has been admitted into the select incurved class by the National Chrysanthemum Society of England. The same honor has been given *Major Bonnafon*, an incurved yellow, but both these varieties, which are of American origin, we know to be of the Japanese type. The yellow sport from *Mrs. H. Robinson*, named *Mrs. O. P. Bas-*

sett, originated with Bassett & Washburn, of Chicago. It is one of the best novelties of the season, equal in every way to its parent, from which it differs only in color. In general appearance Philadelphia probably comes nearest to it, but this variety has proved an uncertain grower, and, besides, is subject to a leaf disease which appears to be hereditary.

Evangeline is another new variety which may be regarded as an acquisition, especially when among scores of new varieties it is the only one of its color worth growing again. It is said to be the white Kiota, which term gives some idea of its form; but I should rather describe it as a white Eugène Dailledouze. Its habit is superb. Symphonia is a compactly built pink of good color. In Defender we have a fine new maroon. This color, in which the flowers do not "burn," is rare. As far as I have seen this variety is free from that defect. John Shrimpton is the best of the older varieties of its color, and better than California, William Seward or G. W. Childs, all of which are liable to "burn." President McKinley will be valuable among crimson and old-gold varieties. The hitherto best-known varieties of this color, Robert McInnes and Edwin Molyneux, have proved difficult to manage. President McKinley is robust, with excellent flowers and the foliage well up to the flower on a terminal bud.

Mermaid is still considered a good pink for exhibition purposes, where large blooms are desirable. Madame Galbraith, a new French white flower, will also prove a favorite for exhibition. It is elegant in build, the lower florets interlacing the stem as the centre builds up. C. H. Molin is an attractive bronzy yellow of exquisite form. It is of the Japanese reflexed type. The long flat florets recurve about the stem as the centre expands until the flowers become perfectly oval. J. W. Richardson promises to be a good commercial yellow, of medium height and splendid habit. L. Ermindra is a lovely saffron flower. There are few Chrysanthemums of this color, and this is the best. It makes an imposing specimen plant. Castleton promises to be a splendid white flower for exhibition. It partakes of the character of the old Robert Bottomly, but makes a full flower.

Wellesley, Mass.

T. D. Hatfield.

### Decorative House-plants.

AMONG the pleasant features of modern house furnishing is the general use of so-called decorative plants, which add a touch of natural grace and beauty to even the most artistic fittings. Enthusiasts have always been able to grow plants in the house successfully under adverse circumstances, but the average householder has neither time nor skill to cultivate a collection of plants under the trying conditions in modern furnace-heated houses. Florists, under stress of competition, have produced great numbers of highly decorative plants at moderate prices, and plant furnishing has become so popular that now the average house contains as many Palms, etc., as bicycles. The list of these desirable plants is short. Four or five species of Palms, Pandanus, Araucarias, India-rubber plant, Aspidistra and Ferns cover the usual list of staple plants from which to select for permanent effects or a ground-work, to which other plants may be added as they are available. As plants become endeared to us, like friends, from long association, it is well to select those rather under the full size desired, and thus secure the pleasure of growing them on.

Any of the Palms ordinarily grown are of the easiest possible cultivation, though they may not be able to survive the attention of careless domestics. If Palms are bought in the spring they should be plunged out in a sheltered border where they are not too much exposed to the wind and can have the sunshine for an hour or two daily. Under this treatment they will have hard foliage capable of enduring the winter with little detriment. Palms bought in the autumn, especially if small, have often passed the summer in the florist's forcing-box frames, and are apt to halt in growth in a living room; they should be hardened off by keeping them in a moderately cool and airy place for a while. The Arecas, Livistonias, Chamærops, Kentias—the ordinary list of Palms—may be grown in glazed pots, but it is less risk to cultivate them in earthen porous pots, which may be concealed in fancy jardinières or vases. Any good open soil suits a Palm, which, while not growing rapidly, requires liberal, but not abundant, supplies of water. Palms also benefit by a fair amount of sun in winter.

Palms in the greenhouse are subject to scale insects. When in that condition I loan mine to the house, finding that the weekly cleaning of the foliage causes the vermin to disappear. This cleaning of the foliage is important if the plants are to be kept in health. Nature usually produces a Palm with a single stem, but probably in answer to a demand, the florists now, by

planting two or three together, secure a "well-furnished" plant, which effectually disguises the stem and character of the species. Pandanus Veitchii (variegated) and P. utilis are both capital house-plants, though, owing to the serrated edges of the leaves they are cruel plants to clean. They will endure many unfriendly circumstances, but not water between the leaves, and they should be watered only below.

Ferns are usually the plants most trying to the housekeeper, as they are generally the shortest-lived and the most expensive part of the plant outfit. The reason is not far to seek. The evergreen Ferns used for home-plants are mostly tender perennials, naturally growing in shade and moisture. Moist surroundings, of course, check respiration, and if the plant is moved to a dry atmosphere it respire faster than the roots can supply the moisture. To add to the trouble the small plants used for filling the table ferneries are often grown in small pots which become filled with matted roots, and if plunged in this condition in the pans the roots are so much less fitted for active work. These small ferneries should be filled with sandy leaf-mold, the roots of the Ferns carefully spread and the pans, after planting, kept in a cool, airy place, exposed to good light, but not sunlight, until the roots are active and the plants hardened. Ferneries so prepared will survive ordinary conditions of the house for months. It is well, however, if we have the facilities of a greenhouse, to prepare several spare pans for each fernery, in which fresh plants may be established to replace the ones in use when these show signs of suffering.

Elizabeth, N. J.

J. N. Gerard.

### The Cultivation of Mushrooms.

THIS is an ideal time for preparing to make Mushroom beds, and if there is enough fresh material at hand for the purpose and a place where it may be laid out for a few days to air and sweeten, there will be no trouble now from flies, which give great annoyance earlier in the year, both before and after the beds are made. Our Mushroom beds have always been made up under the greenhouse benches, and those started early in the fall have always brought out a crop of flies that were hard to dispose of and very troublesome while they lasted.

The difficulty experienced in drying the material sufficiently before making up the beds so that the heat will not exceed one hundred degrees, has always caused us much labor. Sometimes a bed has had to be dug up after it was made firm so as to release the heat. We are now careful to have such absorbents at hand as a few loads of dry loam; this is mixed with the fresh manure and turned a few times, and there is then no great heat generated to dispel the ammonia necessary for the sustenance of the crop. The beds are thus easily made firm, there is no danger of overheating, and the heat being preserved instead of dispelled it lasts much longer in the beds. The crop is correspondingly better and of longer duration. We use about one-third loam and two-thirds manure. Some growers use one-half well-decayed manure and the other half fresh, and this seems to give good satisfaction.

After making up the beds the thermometer must be plunged well down and watched for a few days, and if there is no greater heat than ninety-five degrees it is safe to spawn. A greater heat than this will kill the spawn. At the end of a week if the heat does not rise the beds may be soiled over and made firm with the back of the spade. If the heat goes below seventy degrees a layer of hay about eight inches deep should be put over the beds. The warmth will at once be drawn to the surface near the spawn, and after this the heat may be regulated by adding to or taking off the covering.

There is always uncertainty about Mushroom spawn even to a practiced grower. One has to rely implicitly on what the dealer sends, and it is exasperating to find, after much care and labor, that the spawn is of poor quality. It is curious, too, that it is always the spawn that is at fault. If it has white threads visible on the outsides of the bricks the mycelium has started one stage forward. As this process should take place in the beds themselves, the prospects for a good crop are reduced before planting. But with good fresh spawn, such as is imported by reliable firms in ton lots, there is little danger of failure if proper attention is given to the conditions. We have had great success with the cultivation of Mushrooms under the benches in a Carnation-house. In six years we have never had a total loss of crop, though some crops have been much better than others. A warm cellar would be a much better place and furnish better atmospheric conditions. But in the absence of a cellar one need not hesitate to try Mushrooms in the greenhouse at this season.

South Lancaster, Mass.

## Correspondence.

## Trees and Shrubs for Winter Effects.

To the Editor of GARDEN AND FOREST:

Sir,—The autumn tints in foliage have been unusually rich on the Sugar Maples this season, and Dogwoods and Sumachs were also exceptionally brilliant. The absence of boisterous winds until recently helped to prolong the season of autumn colors. The leaves of the Japanese Maple (*Acer palmatum*) keep bright a long time before they fall, and Oak-leaves will continue showy until severe frost turns their rich vermilion tones to rusty brown. The dry leaves of the White Oaks persist until spring, when the swelling buds loosen their hold, and it is not until May that the last can be gathered from the lawn. The rustle of these dry leaves in midwinter is harsh and mournful, and their melancholy plaint seems to intensify the blizzard's force.

Winter effects in the garden do not generally receive the attention they deserve. Willows with yellow bark, the crimson bark of Dogwoods and the green of *Acer Negundo*, rough-coated Cork Elms and smooth Maples, some gray and some red, lend variety and beauty. Among shrubs we have Roses with red twigs and compact brown bushes of *Spiræa Thunbergii*. Evergreens, coniferous trees and shrubs show an endless variety of color and form. The pyramidal European Larch, as well as its American and Japanese relatives of more spreading habit, even though deciduous, are not without beauty. There are coal-black Yews and golden Yews. *Retinosporas* of bluish and of golden tints; graceful Hemlocks and rigid Spruces. The Douglas Spruce is of a rich bronze-green; *Picea orientalis* is almost black; *P. polita*, brown; *P. pungens*, glaucous, besides the many beautiful forms of *Abies concolor* from the western states, such as *A. concolor violacea* and *A. concolor Veitchii*. And these are but a few of the Spruces and Firs.

The climate of no other country is, perhaps, so well adapted for berry-bearing trees and shrubs, and our sunny autumn weather is most favorable for the thorough maturing of the fruit. While in most cases this will ripen and fall, in many instances it remains throughout the entire winter, providing the birds do not pick it. It is not unusual to see the red berries, or drupels, of *Berberis Thunbergii* showing through the new growth in spring. The same may be said of *B. Sieboldii*, a strong-growing species, recently introduced from Japan, on which the fruit hangs in drooping panicles. Both these *Berberis* have attractive autumn-tinted foliage. The Hawthorns (*Crataegus*) are not without charms in midwinter. The fruit, especially on some of our native species, is large and handsome, and would remain for the greater part of the winter if not eaten by birds. It is an old saying in England that a full crop of haws means a severe winter. Probably the most beautiful of these plants is *C. Pyracantha Lelandi*. It is a low-growing, straggling, evergreen bush, unlike other Thorns, and was once placed in a genus, *Pyracantha*. Its scarlet berries are very showy, and as it fruits freely and is of slow growth, it is a first-class plant for the foreground of the shrubbery.

*Elæagnus argentea*, or Silver Thorn, is pleasing when the summer breeze flutters the silvery leaves and in autumn when the trees are loaded with fruit. In the Arnold Arboretum, among thousands of seedlings, there is one more beautiful than any of the others. It is a plant of *E. umbellata*. This Mr. Dawson will propagate by grafting as a sure means of perpetuating the variety. Another reason for this method of propagating is that the species is unisexual, and probably more than half of the plants grown from seeds would be males, and it is doubtful if the fruit-bearing plants would be as fine as this particular specimen. *E. longipes* has recently come into favor on account of its mild acid fruit, which many persons consider palatable; it is a summer-fruited species, and its season is soon past.

Many wild Roses have showy hips; these are large and orange-red in *Rosa rugosa* and *R. rubiginosa*, the Sweetbrier; red in *R. lucida* and *R. Caroliniana*. The fruit of shrubby Honeysuckles is attractive for a short season in the autumn. *Lonicera Morrowi*, noted last spring as one of the most attractive species when in bloom (see GARDEN AND FOREST, vol. x., p. 227), has now new charm in its decoration of amber-colored berries. All the forms of *L. Tartarica* are interesting in their fruits. Both the American and European Spindle-trees (*Euonymus*) are ornamental when covered with panicles of scarlet fruit. Black Alder (*Ilex verticillata*) grows naturally in low ground, and though a common shrub, it is worth a place for its scarlet fruits alone. The round red berries cluster about the upper parts of the twigs, and stay on nearly all win-

ter. Like the *Elæagnus*, it is unisexual. *Myrica Caroliniensis*, the Candleberry, forms a dense shrubbery, and is a capital bush for planting on gravelly banks. The white resinous matter surrounding the seeds, which accounts for its name, makes an excellent polish for furniture, and is, moreover, pleasantly fragrant. *Symplocos crataegoides*, a recent introduction from Japan, is unique in the color of its fruit, being a rich indigo-blue, with a bloom like that on grapes.

Clusters of shining black fruit tip the branches on Privet-bushes. The fruit itself cannot be called handsome, but the plant is worth a place because it adds variety. One plant of the dwarf, spreading *Ligustrum media* in the Arnold Arboretum will be selected out of thousands for propagating on account of its fine fruit. Privets are among our best flowering shrubs in spring, and a large bank of these plants is a feature of one of the parkways in the Arboretum. The flowers have a sweet perfume. Within the past fortnight a thrifty bush of *Symphoricarpos mollis* in the Arboretum was literally weighted down with large bunches of white fruit. Snowberries are old garden plants and this is one of the best species. The American Mountain Ash, *Pyrus Americana*, is one of the showiest of all trees, with its clusters of scarlet-red fruits.

*Gerbera Jamesoni* is flowering in Professor Sargent's garden at Brookline for the first time in this country. It is a south African plant, herbaceous in habit; it suggests a scarlet Dandelion, but is undoubtedly distinct and will be a valuable addition for winter blooming. The flowers last a long time. *G. Jamesoni* suggests the esteem in which the Dandelion would be held if it were not a common weed.

Wellesley, Mass.

T. D. Hatfield.

## Plum-fruit Rot.

To the Editor of GARDEN AND FOREST:

Sir,—The plum crop in the neighborhood of Boston was nearly destroyed during the past season by a fungus which attacked the fruit as it was beginning to ripen. Can you suggest any method by which the ravages of this pest can be checked?

Newton, Mass.

H.

The loss in Plum orchards during the season just ended was caused by unusual attacks of the gray-mould fungus (*Monilia fructigena*). It is easily distinguished from all other fungal troubles of the Plum by its appearing, as a rule, upon the fruit as it begins to ripen. It grows with remarkable rapidity, causing the plums to decay and coating the fruit with a gray mould as smooth to the touch as powdered soapstone. In this spore-bearing condition the plums shrivel, and may remain as mummified fruit upon the trees for months.

The same fungus attacks the stone fruits generally, and often does as much damage to ripening cherries as to plums. It is one of the serious enemies of the Peach, attacking it earlier in the development of the fruit than in the case of the Plum or Cherry. There is probably a better opportunity for the spores to find lodgment upon the fuzzy coat of the young peach, and the adhering moisture helps them to germinate. The skin is less dense, also, and this favors the fungus upon the peach and retards its early development upon the plum and cherry.

*Monilia fructigena* is by no means confined to fruit, but may attack buds, leaves and flowers. It also spreads down the twig, causing it to die and the leaves to turn brown and hang lifeless in their places. Many experiments have been made to check the ravages of this fungus; and with peaches they have been fairly successful. Professor Chester, of Delaware, for example, has fought this pest to good purpose with the standard fungicides. The sprayings should be made with thoroughness and at frequent intervals if there is a rainy season like the past one. The showers not only wash off the Bordeaux mixture or other fungicide, but furnish the best conditions for the growth of the enemy.

In addition to spraying, orchardists, if they wish to reduce the *Monilia* to a minimum, should see that all mummy fruits are removed from the trees and the soil beneath them, and burned. The dead branches and the leaves should also be removed from the trees and burned in early autumn, or, better still, as soon as found.

As a cultural precaution orchardists would do well to

pay more attention to thinning their fruit and to giving more space about the trees for the free circulation of air. With plenty of room about the trees and for the individual fruits upon the branches, the judicious spraying and removal of all mouldy fruits and dead twigs a grower may reasonably expect to be comparatively free from this pest, provided his neighbors take the same precautions and the season is not excessively wet and cloudy.

Experiment Station, New Brunswick, N. J.

Byron D. Halsted.

## The Forest.

### Natural Reforestation on the Mountains of Northern Colorado.—I.

THE traveler through the mountain region of northern Colorado, even though he make only casual observations, cannot fail to be impressed with the extent of the devastation that has been wrought by forest fires. One may ride for miles through regions where the destruction came in very recent years, as is shown by the blackness, the entire absence of living vegetation and the utter desolation. On other areas the general appearance marks the destruction as more remote; many trees are rotting on the ground; from those standing the bark has been worn away, and their bleaching trunks remain, white and ghostly, the last relics of a once grand forest. On these areas other vegetation has started, and some are sufficiently covered with Grasses and Sedges to afford good pasturage for stock. Here and there are thick groves of young Aspens, bordered with scattering shrubs, Elder, Buffalo-berry, Shad-bush, Currants and Gooseberries, or the whole may be covered with a growth of shrubs intermingled with scattering Pines and Spruces. Sometimes this new coniferous growth is scanty, and again it is abundant, covering the whole surface and forming dense forests. Other areas must have been denuded at a still earlier period, and here the evidence of a former forest growth is reduced to a few rotten remnants of stumps or trees. Some of these areas are now timbered with new coniferous growth, others are nearly barren of vegetation.

In addition to these districts that bear evidences of having been at some time denuded of forest growth by fires, there are at middle elevations (7,000 to 8,000 feet) areas of considerable extent that do not now show any signs of ever having been timbered. They are the rounded tops of low mountains, or the exposed plateau-like terraces that lie between them. These are usually rocky, or at least gravelly, and may be entirely bare of timber or sparsely covered with the Yellow Pine. By far the greater portion of the injury to forests has been done in the middle-altitude region (from 7,000 to 9,000 feet), although the effects of fire can be traced in places from the foot-hills at 6,000 feet nearly or quite to timber-line. The forest areas yet remaining intact are mainly those of the subalpine belt, from 9,500 feet up to timber-line. Their escape from destruction is due in great part to the prevailing moist condition of the high zone. The winter snow body is usually heavy, and so slowly does it yield to the summer sun that the saturated condition of the soil holds through the season, and it rarely happens that conditions exist favorable to the spread of fires. The snowfall is commonly less at from 9,500 feet and downward, and it disappears early in the summer, and there follows a period favorable to the spread of fire.

Estimates of the areas that have been devastated in this region are very unsatisfactory. The abrupt and broken contours of the region, the irregularity in the forest bodies and in the burned districts make it exceedingly difficult to form an accurate opinion. Such estimates as I know of are crude approximations, and I may as well pass the question with the general statement that the area is very great.

During the last eight years several trips have been made

through the mountains of Larimer County to the crest of the Front Range, or over the Medicine Bow Range and on across the continental divide west of North Park, and I have noted with much interest the progress of growth in Nature's effort to reclothe the denuded areas. The observations have suggested numerous interesting questions which in the main are unanswerable because of the entire absence of records, or of reliable information as to the time when certain areas were burned. It would be interesting to know with some degree of exactness the time required to start a new forest growth on a burned area, but recorded observations are wanting. Some areas may and do remain bare for long periods, while others will develop new growth within a comparatively few years. The time may thus vary greatly, because growth is so dependent upon local surroundings. Denuded areas in the subalpine region, where the rainfall is commonly greater than below, show the influence of the abundant moisture in the quantity and vigor of the herbaceous vegetation which first follows a fire, but observation leads me to the conclusion that in the higher altitudes the forest trees are much slower in starting, and that they start in less numbers and develop much more slowly than in the lower regions.

That several years commonly elapse between the burning and the starting of new coniferous growth seems indicated by the two following observations, the first in the Cañon of the Cache la Poudre, on a tract that was burned, according to reliable authority, in the summer of 1881. As examined in 1894, thirteen years after burning, grasses were abundant among the dead logs, there were a few shrubs, and a scattering growth of Pines (*Pinus contorta*, var. *Murrayana*), the largest of which was twenty inches high and seven years old. Here it was apparently six years after the fire that the first Pine-tree started. The other observation was made on a tract extending south and west from Chambers Lake, which was burned over in July, 1890. I passed through the burned district a month after the fire, and was greatly impressed with the absolute desolation. No green thing remained; the ground, and everything upon it, was clad in somber black; animal life was absent, and there was something so oppressive in the desolate solitude that I was glad to reach green timber again. A second visit to this tract was made four years later, in July, 1894, and it was with a feeling of keen disappointment that I noted how slight a change four years had wrought. The intense blackness had been subdued in some degree by the action of the elements; some trees had fallen and others were losing their bark, but the general appearance of desolation remained. A very few straggling plants of Grasses and Sedges were the only evidences of returning vegetation.

Colorado Agricultural College.

Charles S. Crandall.

## Recent Publications.

*Flowers and their Friends.* By Margaret Warner Morley. Boston: Ginn & Co. 1897.

We recently spoke favorably of this author's book entitled *A Few Familiar Flowers*, and the present volume, which is addressed to children, and young children, too, apparently, confirms the impression then made that the author knows how to write about scientific subjects in a way to attract those who are addressed. To give children some notion of the ecology, physiology and histology of plants as understood to-day is no easy task, and we can forgive the pursuance of some rather cheap methods if the end is really attained, as it has been, we believe, in this case. Whether in teaching children it is necessary to intersperse so much loquacity we will not consider; but we are sure that some of it might have been omitted in this book with advantage. The teaching itself, so far as we have seen, is correct and modern, and the subjects in some cases so well presented that parents as well as children may find profit in the instruction.

## Notes.

Six medals were recently awarded to Ellwanger & Barry, Rochester, New York, by the Gartenbau Ausstellung, in progress at Hamburg, Germany, for exhibits of fruits. Two of these medals are gold, two are silver and two bronze.

The American Forestry Association invites competitive designs for a corporate seal, these to be submitted to a jury of artists who are named in the announcement. Specifications as to size and other details are also given, and all designs must be entered not later than January 5th, 1898. Mr. George P. Whittlesey, Atlantic Building, Washington, District of Columbia, may be addressed for further particulars.

An exhibition of foliage and flowering plants and cut flowers is announced for November 12th and 13th at the Hotel Astoria, in this city. The exhibition will be managed by the New York Gardeners' Society, under the patronage of ladies prominent in social life and active in philanthropic work. The proceeds will be applied to charity. Exhibits include classes for private gardeners and classes open to all, and prizes will be awarded. J. H. Troy, 365 Fifth Avenue, is the general manager, to whom all communications should be addressed.

A State Forestry Society was organized at Raleigh, North Carolina, on October 21st, with fifteen members. The society elected Mr. W. E. Petty, Carthage, President; Dr. C. A. Schenck, Biltmore, Vice-President; Professor W. W. Ashe, of the North Carolina Geological Survey, Secretary and Treasurer. The main object of the society is to lessen forest fires in North Carolina, which are doing great injury to Pine lands, especially in the south-eastern part of the state, in the valley of the lower Cape Fear River. Methods of improving the condition of lumbered and deteriorated woodland will also be considered, and the reestablishment of waste and eroded agricultural lands in timber.

Of all the Viburnums hardy in northern gardens Viburnum molle retains longest the summer green of its leaves, and this year it is as green and fresh at the Arnold Arboretum in the last week of October as it was at midsummer, although some of the other species have lost their leaves entirely, and the autumn beauty of many others is rapidly passing. The Japanese Viburnum tomentosum, however, is still handsome with leaves partly green or entirely dull bronze-red, and Viburnum Lentago is yet splendid in its deep red coloring. Viburnum molle, which is still little known in gardens, is a southern plant just reaching the shores of Cape Cod, but it is as hardy as any of the more northern species in the neighborhood of Boston. It is a large shapely shrub with ample leaves; the flowers open later than those of the other Viburnums, and are followed by beautiful blue fruits which retain their bright color until very late in the autumn. Altogether this is one of the most desirable garden plants in a group which has given to northern gardens some of its best ornaments.

Pomegranates, from Spain, have been shown in the fancy-fruit stores during the past two weeks, and find a moderate demand at sixty cents a dozen. Fresh figs, from Florida, cost twenty-five cents a quart. Florida and Jamaica oranges, Mandarins and grape-fruits, luscious Japanese persimmons, and large bunches of Black Hamburg grapes, grown under glass in England, are a few of the choice fruits of this time. Green Gages, from this state, Coe's Late Red and German plums and Gros prunes, from California, Idaho and Oregon, are still occasionally seen. Large Abakka pineapples, and Bartlett pears held over in cold storage, are among the most costly offerings. Apples add to the showy effect of every collection of fruit, and among the best sorts in market now are western Jonathans, Virginia Albemarle Pippins, Wine Sap and Johnson's Winter, from the same state, Snow, Northern Spy, Greening and King, from New York. The offerings of fruits by Italian and Greek vendors on the streets are as abundant now in early November as in midsummer, and in the less glaring sunshine of these clear, crisp days, the displays seem even more showy, although many brilliantly colored fruits are no longer in season. Bananas from Jamaica and Central America are sold at from twelve to twenty cents a dozen. Large Beurre Bosc and other late varieties of pears, from California, cost from one to three cents each, and their solid spicy flesh makes them a particularly satisfying portion for a small outlay. The best of the less costly apples, such as Ben Davis, from Virginia and New Jersey, Baldwins, from New York, and Phoenix, from New Jersey, are popular, together with choicer varieties of the grade known as fair in the wholesale trade. Handsome Flame Tokay grapes, from California, cost ten cents a pound, and large, handsome Black Moroccos sell for the same price.

Professor Waugh has recently organized a Horticultural Seminar, which is intended to be a centre of advanced horticultural study in the University of Vermont, and membership is restricted to students taking advanced elective studies in the department. An opportunity is offered in connection with the Seminar to take up lines of individual study. Special electives may be taken in the following subjects, among others: Advanced study in evolution, pomology, landscape-gardening; library courses on special topics; critical study of French or German horticultural works; experimental problems. Mr. John Craig, Dominion Horticulturist, was present at the first meeting and spoke on The Geographical Distribution of Fruits in Canada. At the second meeting Professor Waugh read a paper on Ideals of Horticultural Instruction, and at the third meeting Professor F. C. Sears, of Wolfville, Nova Scotia, formerly of the Utah Agricultural College, spoke on Horticulture in Utah. As stated in his article on Horticultural Instruction in Colleges last winter in GARDEN AND FOREST (see vol. x., p. 89), Professor Waugh regards individual assignments as of special importance. As an example of the scope of the work in the University of Vermont, the following thesis subjects among those prepared for the class in evolution may be mentioned. Abstracts of these theses constituted the programme of a meeting of the University Botanical Club: Alpine Flora of Vermont, its Origin and Distribution; Progression and Degeneration in Evolution; Growth Force as a Source of Variation; The Hereditary Transmission of Disease; Evolution of the Petunia; Cross-fertilization and Hybridization in Rosaceæ; The Inheritance of Acquired Characters; Weismannism, a Study of the Writings of Dr. August Weismann; Naegeli's Philosophy, a Study of the "Mechanisch-physiologische Theorie der Abstammungslehre"; Early Maturity as a Question of Phylogeny; Physiological and Climatological Constants: The Relation of Climate to Plant Phenomena.

Japanese peanuts are a novelty at Davy's, the nut-store on lower Fulton Street which has grown familiar to New Yorkers in the past forty years. These peanuts are of uniform size and considered superior in flavor to the Virginia product. In England Japanese peanuts enter into successful competition with those from our southern states, but this is the first attempt to introduce them into America, at least into the Atlantic coast states. In Virginia and other southern states peanuts are hand-picked, the stems being removed and poor nuts rejected, and they are cleaned of earth and dust in fan-mills. These Japanese peanuts have undergone no special preparation, and so are less attractive. But heavy expense for freight is the most serious hindrance to the establishment of this trade with Japan. Seeds of the Japanese peanuts have been planted in Virginia with a view to obtaining a superior strain for cultivation here. About 85,000 bags of peanuts were marketed in this city during the current year, each containing about four bushels. Most of these come from Virginia, with occasional shipments from North Carolina. Those from the latter state are, as a rule, of smaller size. The new crop is usually on the market by November 1st, and advance shipments are now expected daily, though the season is belated about a fortnight, owing to recent heavy rains in the south. Generally the crop is gathered during six weeks following the middle of October. In an exceptionally forward season new peanuts have been offered in New York on October 16th. Four grades are recognized, known as fancy hand-picked, extra hand-picked, third grade and "pops," the latter being small and empty or poorly-filled shells blown from the mills during the cleaning process. Many of the lower-grade peanuts are shelled by machinery in Virginia for confectioners' use. A small variety, grown from Spanish seed, is most in favor with confectioners. Many years ago one New York house handled about one-twentieth of the entire crop of southern peanuts. But this trade has greatly changed, and the business is now mostly done in Norfolk. Formerly peanuts were sold by the bushel, but during the past twenty years wholesale lots have been handled entirely by the pound. Five cents is a fair average wholesale price for the grade known as fancy hand-picked. Forty years ago one of the Mexican or Spanish silver "shillings" current in this city, and valued at twelve and a half cents, was the retail price of a quart of peanuts. Later, the same quantity cost twenty cents, and at this time, ten cents. A common name for peanuts among the negroes of Carolina and Georgia is goobers, and ground-nuts is a not unusual name south of New York. Peanut-plants, occasionally seen here as a novelty, are singularly interesting to those not familiar with their habit of growth, in the small orange-colored blossoms in the axils of the leaves and the stems which find their way into the soil from this part of the plant, and nourish the fruit, which is borne underground.

New Dangers to Public Parks.

IN praising the man whose recent death means a heavy loss to the readers of this journal, and in noting his long usefulness as the most keen-eyed and devoted defender of the public parks of New York, the daily papers have dwelt forcibly upon the dangers which threaten these parks from the “assaults of the ignorant and vicious.” But the parks are threatened by other dangers, newer than these, more subtle and insidious, less easily recognized as dangers, and therefore less likely to be frankly and forcibly resisted. And the consciousness of this fact greatly augments, among those who keep close watch upon our parks, the regret which every intelligent American must have felt when he heard of the death of Mr. Stiles.

The ignorant and the vicious have long been enemies of the parks—persons who deny their utility because it cannot be translated into terms of dollars and cents; those who are eager to injure them for the sake of giving to the city something, advantageous, perhaps, in its own way, which they think of more “practical benefit”; who wish to exploit them for their own profit or who plan to fill them with ugly objects; who barbarously injure their grass, trees, flowers or monuments for their own mischievous pleasure; or who think they know more about caring for them than their professional superintendents, and therefore try to “arouse the public” whenever a dying tree is cut or any other needful and desirable work proposed.

These people represent the unintelligent, uncultivated and unconscientious elements of the population. They are now recognized as enemies of the public, which in some degree is on its guard against them. Teachers, champions and leaders are still needed to defend the parks from their possible attacks. But the public is now easily roused to oppose their worst efforts; and it is probable that no such bold assault upon Central Park will again be attempted as the effort made a few years ago to run a speedway through it, or the equally horrible one to turn part of

it into a barren parade-ground. And the public may likewise be counted upon, although not so confidently, to forbid the attempts of individuals to dot it with penny-in-the-slot machines or newspaper kiosks, or otherwise to disfigure it and to pervert it from its true service for the profit of personal greed under the pretense of supplying special “conveniences” or “pleasures” to its frequenters.

The danger to our pleasure-grounds from engineers necessarily employed upon them, but devoid of the right artistic feeling and unwilling to abide by the counsels of landscape-gardeners, has recently been dwelt upon in these pages and may for the moment be passed by. What we wish now to point out is that it seems probable that more and more schemes to further definitely intellectual or æsthetic ends will be prosecuted without due regard to the integrity and beauty of our parks as works of landscape-art, and that the patrons of science and literature and of art of other kinds are likely to try to injure our great artistic creations like Central and Prospect Parks. And this is, of course, a very insidious danger, as the schemes may be worthy in themselves, and the people who urge them are those whom the public has been told it should trust most implicitly in intellectual and artistic matters.

It is at least a question whether the new Public Library should have been allowed to claim the site of the old reservoir on Fifth Avenue, which otherwise would have been added to the area of Bryant Park. The Metropolitan Museum should not have been given a site within Central Park, but placed beyond its limits, as the Museum of Natural History was upon its western borders. And the stand which Mr. Stiles took, as Park Commissioner, in opposing the desires of the Botanical Society—which, if carried out, will seriously impair the peculiar beauty of Bronx Park and its utility as a public pleasure-ground—must convince all the readers of this journal, who know of his devotion to botany and horticulture and to the task of spreading an interest in them among the people at large, that here, too, a great mistake has been made, and by just the kind of persons who ought to be trustworthy guides with regard to the right conservation of the public’s park-lands.

These few instances illustrate one phase of apprehension—the danger that buildings for public purposes will more and more absorb the narrow and precious spaces set apart for the people’s refreshment and enjoyment. Each such instance is deplorable in itself and as a precedent for future enterprises of similar kind. Nor is New York the only city which needs to be warned along these lines. The beautiful park which Mr. Olmsted laid out in Buffalo is threatened with the erection of buildings which would be public benefits if placed elsewhere, but public misfortunes as features in a naturalistic park. Even the small and incomparably precious State Reservation at Niagara Falls has had to be defended against a misfortune of a like sort; and there is no town in the United States whose parks are safe in this respect. It is high time that the public should awaken to the fact that no buildings whatsoever, except those absolutely required for park purposes proper, should be allowed within a park, and that the projectors of all others should buy their own sites or, if these must be purchased with public money, that they should be placed outside of park limits.

This is not merely because every foot of open public land is precious as such and should be held sacred to serve the health, the refreshment, and the outdoor pleasures of the people. It is also because, almost without exception, our pleasure-grounds are works of landscape-art in the exact sense—naturalistic parks—and are necessarily injured in their artistic character by the intrusion of buildings even of the most beautiful kinds. This is the point which many artists do not understand, and, therefore—as they are naturally regarded as the highest authorities in artistic matters—the damage which may be done to our parks by those who have not a true comprehension of them is, per-

haps, more to be dreaded than that from any other class of men.

It was hailed as a very good sign when, only a few years ago, American architects began to interest themselves in the environment of their buildings, and to regard it as an integral part of the works of art which they wished to create; but there are many indications that it is not always realized that while in some cases planted grounds must be mere adjuncts to buildings, in other cases the grounds are themselves the primary and important work of art, and that in the latter case no artificial object should be placed within them which does not serve their own proper purposes or enhance their own intrinsic beauty. As yet architects and sculptors do not always understand these truths. Individually and in corporate ways they have recently shown a great interest in the parks; they have done many things to improve them, and have prevented the doing of many things which would have injured them. But they have also proposed, if not achieved, some things which would be of lasting detriment; and the danger is that, as their interest in our pleasure-grounds develops they will more and more come to regard them as mere frames and settings for their own products, or possible exponents of their own gardening ideas. If sculptors and architects ever regard our parks simply as "good places" for the display of monuments and statues, they may grievously wrong the community by defacing its most precious artistic possessions. A man naturally intent upon showing his own work to advantage is easily tempted to think that the best site for it is the place where it will be most conspicuous; and the wide-open areas of a park specially appeal to his desires in so crowded and ill-planned a city as New York; but it is certainly clear that parks like Central Park are in themselves more valuable, even from the artistic point of view, than any object which can be placed within them, and that their beauty is of such a kind that it may easily be marred by the intrusion of an object in itself artistic. An architect may find it difficult to realize that the creation of a formal passage may fatally injure a work of landscape-gardening, planned in accordance with artistic laws less fixed and rigid than those of their own art, but none the less logical and binding, and this point of view sometimes leads him to think he understands the whole subject and is capable of "improving" the best work of such a master as Mr. Olmsted. This is no vague and unsupported assertion. It is well known that one of the most prominent and highly cultivated architects in New York has long declared that a straight boulevard ought to be run all along the eastern side of Central Park, within its borders, and has actually prepared a plan for such a boulevard and wished to have it adopted by the city authorities—a plan for a piece of in-artistic vandalism quite as glaring as the once-proposed speedway along the opposite side of the park.

In short, Central Park and almost all other American parks are naturalistic parks—are works of landscape-gardening, and their artistic value and greatest usefulness will be impaired by the intrusion of any building, however excellent it may be in design or useful in purpose, or of any statue or other monumental work, however great its artistic or historical value. Our great parks are country parks, and they are valuable to city communities not as museums or statue galleries, but as bits of country where the weary and discouraged can draw new breaths of life and hope from country sights and scenes.

THE Twenty-second Annual Report of the Commissioners of the Department of Parks of the City of Boston is before us and shows that up to the end of last year the Department had expended \$6,165,780.47 for land and \$7,568,099.24 for construction, or with \$13,356.10 for betterment expenses, a total of \$13,747,235.81, against which \$361,334.96 has been collected for betterments. The report shows that the work of completing the parks was

industriously carried on during the year. About two millions and a half are still needed to finish them according to the original designs of the landscape-gardeners, including nearly \$300,000 for buildings. The Commissioners suggest, however, that these estimates can be considerably reduced. The most significant thing in the report to those interested in the best development and care of the Boston parks is the announcement that during the year the services of a competent superintendent and general manager for the system have been secured, and that the irresponsible dual management, which has always existed since Boston has had parks, has at last been abandoned.

The following extract from the report of the landscape-gardeners, Olmsted, Olmsted & Eliot, to the Commissioners is of such general interest to all parkmakers that we are glad of an opportunity to reproduce it for their benefit: "There are certain parts of the parks, especially along the borders of waters and in existing rocky woodlands, where we have designed to have unusually wild and natural effects. For the gardener to plant in such situations exotic trees and showy garden shrubs and perennials would go far toward defeating the essential elements of our designs. The roads and paths of 'country parks' are placed in certain positions so as to command certain landscapes or bits of scenery thus and so, and conversely the vegetation, which in this climate makes the scenery, must be controlled, encouraged or modified accordingly. Unless planting, thinning and clearing are thus done sympathetically, the courses of the roads become meaningless and their cost is wasted."

#### Notes on Cultivated Conifers.—VI.

**THUYA**, or *Arbor-vitæ*, is a genus of four species, two being North American and two east Asiatic. It is well distinguished by its erect cones ripening at the end of their first season and composed of oblong, slightly imbricated, acute scales usually with from two to four seeds under each scale. All the species are pyramidal aromatic trees with flattened, lateral, pendulous or erect branchlets disposed in one horizontal plane and forming an open distichous spray, and dimorphic leaves. The species are grouped in two sections—*Euthuya*, to which belong the two American and the Japanese species, and which is distinguished by pendulous branchlets and thin, leathery, oblong, acute, mucronulate cone-scales, those of the two or three middle ranks being larger than the others and fertile, and by its compressed light chestnut-brown seeds with broad lateral wings and minute hilums. The second section, *Biota*, with a single Chinese species, is distinguished by erect branchlets and thicker and conspicuously umbonate cone-scales, the lowest four usually being fertile, and by its much-thickened dark red-purple seeds rounded or obscurely angled on the back and marked by large oblong conspicuous hilums.

The type of the genus, *Thuya occidentalis*, the *Arbor-vitæ* of gardens, is a native of eastern North America, being distributed from Nova Scotia to the shores of James Bay and Lake Winnipeg, and southward through the northern states and along the Alleghany Mountains to southern Virginia. It is an inhabitant of wet ground, often at the north covering great areas of springy swamplands with impenetrable forests or growing on the rocky borders of streams in situations where its roots can obtain an abundant supply of water, while at the south, where it is comparatively rare, it is found only on the banks of mountain streams. Under favorable conditions it occasionally attains the height of fifty or sixty feet and forms a stout much-branched and buttressed trunk sometimes six feet in diameter. Such specimens, however, are exceptionally large, and trees thirty or forty feet in height, with trunks two or three feet in diameter, are much more common. The *Arbor-vitæ* was probably the first American tree cultivated in the Old World, as it was known in Paris gardens before the middle of the sixteenth century, and

Belon in 1558, in the first book devoted to conifers, published the earliest description of it.

Too stiff and formal, perhaps, in outline, when it is planted as an isolated specimen on high ground, where it usually appears out of place and out of harmony with its associates, the *Arbor-vitæ* is admirably suited for massing on the borders of streams and lakes, where it properly belongs and where it harmonizes with its surroundings. It bears clipping well, and its value as a hedge-plant was shown many years ago by Mr. A. J. Downing, who made it popular in American gardens for this purpose. Few trees show a greater tendency to seminal variation, and many forms have been raised and propagated by nurserymen, no less than forty being described in a recent European work on conifers, while there are several others known only in American gardens. Many of these forms show their distinctive characteristics only while young, and soon grow into the normal form, and in some cases several names have been given to the same plant originating independently in different nurseries. It would not be profitable to describe even a few of the most distinct of these plants, for any one who will sow a quantity of *Arbor-vitæ* seeds will be sure to find among these seedlings a number of forms as novel and interesting as any now in cultivation. It is, however, worth stating again, perhaps, that a plant commonly known in this country as the Siberian *Arbor-vitæ* is a form of *Thuya occidentalis* which originated several years ago in Ware's nursery, in England, and that it is correctly called *Thuya occidentalis* Wareana. All the abnormal forms of *Thuya occidentalis* can be propagated by cuttings, which strike readily, and among them are some exceedingly dwarf compact plants which are sometimes useful in small gardens and on the margins of beds of larger conifers.

The plants commonly cultivated under the name of *Thuya plicata* are garden forms of our eastern *Arbor-vitæ*, and must not be confounded with the *Thuya plicata* of Don, which is more frequently known as *Thuya gigantea*, although Dr. Masters has recently clearly shown that *Thuya plicata* is the older name. This is the *Arbor-vitæ* of north-western America, the Red Cedar of Oregon and Washington, the greatest of all the *Thuyas*, and a veritable giant among conifers. Near the shores of Puget Sound it is a common occurrence to see this tree 200 feet high with a massive trunk gradually tapering from a base fifteen or sixteen feet in diameter. As it grows in its native forests it is one of the most beautiful and graceful of the American conifers, with bright cinnamon-red bark and a narrow spire of branches, which sweep out gracefully from the stem, and are clothed with great Fern-like, pendulous, yellow-green branchlets. Nowhere forming pure forests, the western *Arbor-vitæ* grows singly or in small groves generally on low, moist bottom-lands or near the banks of streams, and less commonly on dry ridges and mountain slopes, which it sometimes ascends in the interior to considerable elevations, although it is only at the sea-level and under the immediate influence of the ocean that it grows to its greatest perfection. Ranging along the coast from southern Alaska to northern California, it penetrates also eastward along the banks of mountain streams through southern British Columbia and Washington to the western slopes of the northern Rocky Mountains, and is abundant on the Bitter Root and Cœur d'Alene ranges and in the territory north of Flat Head Lake. Plants obtained several years ago from this interior and comparatively dry region have proved hardy in the Arnold Arboretum, and in Mr. Hunnewell's Pinetum, where they are now growing rapidly, and promise to become large and handsome trees. In western Europe *Thuya plicata* flourishes, and large specimens are now common in European collections, in which a few seminal varieties with abnormally-colored foliage are preserved.

The Japanese *Arbor-vitæ*, *Thuya Standishii*, is a rare inhabitant of the mountain forests of the main island, and occurs only on the borders of streams and lakes usually at elevations

of 4,000 or 5,000 feet above the level of the sea. It is a small pyramidal tree occasionally thirty feet high, and very like our eastern *Arbor-vitæ* in coloring, but of more open and graceful habit. For thirty years it has been an inhabitant of American and European gardens, where it is much more generally known as *Thuyopsis Standishii* than by its true name. There is a well-formed and perfectly healthy specimen of this tree about eighteen feet high in Mr. Hunnewell's Pinetum.

The Chinese *Arbor-vitæ*, *Thuya orientalis*, the type and only member of the section *Biota*, is a small bushy tree with bright green foliage, and an inhabitant of the mountain districts of central and northern China. Long supposed to be a native of Japan, where for centuries it has been a favorite garden plant and where a number of abnormal forms have been perpetuated, it was probably one of the numerous plants carried by Buddhist priests from China to that empire, whence it found its way to Europe a hundred and fifty years ago, and now in all temperate countries it is one of the most commonly cultivated conifers. Hardy in sheltered positions as far north at least as eastern Massachusetts, the Chinese *Arbor-vitæ* is more common and far more vigorous and beautiful in southern than in northern gardens. Many varieties of this plant are propagated in European nurseries, but none of them is as hardy here as the typical form. The most remarkable of these varieties, perhaps, is the plant with long slender, flexible pendant branches (var. *pendula*) found by Thunberg in Japanese gardens and once believed to be a distinct species. In English and French gardens a dwarf globose and compact form (var. *aurea*) raised many years ago in the Knapp Hill Nursery, at Woking, is a favorite ornament. This plant has not proved hardy at the north, although south of New York it can be successfully cultivated. On this form the early spring growth is rich golden yellow, changing late in the season to the normal light green of the species. *Thuya orientalis*, *Meldensis*, which originated at Meaux, in France, in 1853, and was formerly considered a hybrid between *Thuya orientalis* and *Juniperus Virginiana*, is a juvenile state of the Chinese *Arbor-vitæ*, with acicular spreading leaves. All these plants, like all other *Cupressineæ*, can be propagated by cuttings which usually root rapidly.

*Thuiopsis* chiefly differs from *Thuya*, to which some authors unite it, while others consider it a *Cupressus*, in its ligneous cone-scales, much thickened and dilated at the apex, each bearing five seeds. The only species, *Thuiopsis dolabrata*, which is one of the most beautiful conifers of Japan, is easily recognized by its broad coriaceous leaves, which are convex and bright green above and concave and silvery white below, and are arranged in four ranks in opposite pairs, those on the upper and under side of the branchlets being closely appressed against the stem, while the lateral leaves are more or less spreading. In central Hondo this tree is common between five and six thousand feet above the sea-level, growing as an under-shrub in the dense shade of Hemlock forests, and every year buried in snow during four or five months. Sometimes it rises, however, when its crown reaches the light, to the height of forty or fifty feet, with a slender trunk covered with bright red bark, long, graceful drooping branches and a narrow pyramidal top. It is a tree which evidently requires shade and protection, at least while young, and in its native forests even the largest plants are surrounded and overtopped by taller trees.

In western Europe *Thuiopsis dolabrata* grows admirably, and there are already handsome, well-formed specimens in many of the gardens of southern England and Ireland and western France, but in this country it suffers from summer drought, and unless it is protected from the winter sun it soon perishes or becomes shabby and unsightly, although in sheltered positions it is hardy enough in eastern Massachusetts, and if winter conditions similar to those it enjoys in Japan and sufficient summer moisture could be given to it here, it might be expected to succeed. A form in which the

tips of some of the branchlets are white (var. *variegata*) has come from Japanese gardens, which have also given us a compact form with rather more slender branches and lighter green foliage than those of the ordinary form (var. *nana*), and there are one or two other varieties represented by names, at least, in European collections.

*Libocedrus* bears in many respects a close resemblance to *Thuja*, from which it chiefly differs in the structure of the fruit, which is composed of four or six scales, those of the lower pair being thin, reflexed above the middle and much shorter than those of the next pair; these are thick, woody, and wide-spreading at maturity, while the two inner scales when these are present are confluent into an erect woody septum. Eight species of *Libocedrus* are now known. One of these species is a native of semitropical south-western China; two are scattered through the mountain forests of western South America, from Chili to Patagonia; two inhabit New Zealand; two New Caledonia, and one western North America, where it ranges from southern Oregon along the mountains to Lower California. This, the *Libocedrus decurrens* of botanists, is a noble tree often one hundred and fifty feet in height, with a tall, slightly lobed trunk covered with bright cinnamon-red bark and sometimes seven or eight feet in diameter, and slender branches which are clothed with flattened pale yellow-green frond-like branchlets and which, erect above, and below sweeping downward in graceful curves, form for a century or so a narrow, open feathery crown which later becomes irregular in outline by the greater development of some of the branches which from horizontal become upright, and secondary stems.

*Libocedrus decurrens* has been cultivated in Europe for more than forty years and has already grown there to a considerable size, promising to become a long-lived and large tree. In the city of Washington there are good, healthy specimens in the grounds of the Department of Agriculture and of the Soldiers' Home, and this tree appears to be hardy near Philadelphia and New York. In New England it has not been sufficiently tested yet, but as its range is coextensive with that of the Sugar Pine, which is hardy in eastern Massachusetts, it is possible that it can be made to thrive in this part of the country if it is obtained from a cold, dry region like that at the eastern base of the Cascade Mountains of southern Oregon, or from northern California. It may be worth mentioning that in at least nine out of every ten European nurseries, owing to the mistake made by one of the early seed collectors in western America, *Libocedrus decurrens* is sold as *Thuja gigantea*, while the true *Thuja gigantea*, or, as it is now called, *Thuja plicata*, is sold as *Libocedrus decurrens*.

## Plant Notes.

### *Spiræa arguta*.

THIS plant, one of many hybrid *Spiræas* raised at the Forest School at Munden by Dr. Zabel, is a decided acquisition as a garden plant, and one of the most beautiful *Spiræas* in cultivation. It is described by Dr. Zabel\* as a hybrid between *Spiræa multiflora*, itself a hybrid between *S. crenata* and *S. hypericifolia*, and *S. Thunbergii*. Flowering very early with *S. Thunbergii*, it surpasses that plant in the gracefulness of its arching branches, its more abundant and larger flowers, and in its greater hardiness, the ends of the branches of *Spiræa Thunbergii* being almost invariably killed by the cold of northern winters, which occasionally also destroys a large part of the flower-buds.

*Spiræa arguta* in the Arnold Arboretum, where it has been growing since 1893, is now about four feet high, with slender stems covered with lustrous red-brown bark and furnished near the extremities with numerous elongated,

clustered, arching wiry lateral branches, which about the first of May, just as the leaves are unfolding, are covered on the upper side with crowded umbels of pure white flowers a quarter of an inch in diameter, and raised on slender pedicels about half an inch in length. The pale green leaves are oblong-ovate, entire below and coarsely toothed at the acute apex.

Our illustration on page 443 of this issue, from a photograph made at the Arnold Arboretum by Mr. James F. Codman, represents the end of a stem of *Spiræa arguta* with its numerous lateral flower-bearing branches which, erect in the illustration, are pendent on the plant.

## Foreign Correspondence.

### London Letter.

**NYMPHÆA O'MARANA.**—Kew is indebted to Mr. H. A. Dreer, of Philadelphia, for a tuber of this hybrid Water-lily, and the plant has been an attraction among the tropical aquatics for the greater part of the summer. It was described in *GARDEN AND FOREST* (vol. viii., page 96), where its origin is stated to be due to a cross between *Nymphæa dentata* and *N. Sturtevantii*, the latter a hybrid of rare quality, but, with us, not free-flowering. In its bright rose-pink color, with an almost pure white stripe down the middle of each of its two dozen or so broad petals, *N. O'Marana* differs from all other tropical *Nymphæas*. Mr. Dreer states that with him the flowers were from twelve to fifteen inches in diameter. At Kew they have not exceeded nine inches. Probably, however, the flowers are larger when the plants are grown in full sunshine. In my opinion this is one of the three best forms of *N. Lotus*, the other two being *N. dentata* (white) and *N. Devonensis* (red). If we add to these *N. Zanzibarensis* (blue-purple) we have a quartette of the best tropical *Nymphæas*.

**CRESTED-FLOWERED BEGONIAS.**—The latest "freak" of the tuberous Begonia is the development of a plumose crest on the inner surface of the petals, not unlike that developed by the Persian Cyclamen. This crested Begonia originated in a Continental garden, the stock being secured by a nurseryman who has lately distributed seeds from which a large proportion of the plants raised has possessed this crested character. It is noteworthy that sports of this nature are hereditary, for Messrs. Low & Co., to whom we owe the origin of the crested Cyclamen, found that ninety per cent of the plants raised from its seeds had crested flowers. At present the crested Begonia is merely a curiosity; some growers call it a disfigurement, but there is no saying what it may lead to. A Begonia with flowers like a Cockscomb *Celosia* would no doubt find many admirers. "The case of cresting shows that the plant possesses the power to strike out a new line and to develop characters which would even be regarded as having specific value," has been said.

**BEGONIA GLOIRE DE LORRAINE.**—One of the most charming exhibits recently seen at the meetings of the Royal Horticultural Society was a group of about thirty plants of this Begonia. Each plant grew in a five-inch pot and was eighteen inches high and wide, forming a compact ball-like cluster of bright green leaves and elegant rose-pink flowers. They were grown by one of our cleverest market nurserymen, Mr. May, of Edmonton. I mentioned this hybrid in a letter last December, but, good as the plants were that I had seen then, they are eclipsed by those now noted. Some of the *Socotrana* hybrids are "miffy"; indeed such plants as *Winter Gem* and *John Heal* may be described as difficult to manage, but *Gloire de Lorraine* is as easily grown as *Begonia Dregei*, one of its parents. In addition to its good qualities of freedom of growth and charm of flower it has also that of durability, plants in flower in October remaining in beauty until February or March, the racemes gradually extending in length until they have long flexuose stalks. It is a most valuable winter-flowering plant for the warm greenhouse.

\* *Die Strauchigen Spiræen der Deutschen Gärten*, 22.—*Gard. Chron.*, ser. 3, xxii. 3, t. 1.

**STREPTOCARPUS**.—We have now a great range of flower color among the hybrid *Streptocarpus*, and along with it a habit and leafage which commend the plants to the grower of decorative plants more than the earlier crosses did. It is now generally known that several species were originally crossed to produce this race, the species used being widely different from each other. This fact makes it very remarkable that the crosses are now so far fixed in character that the various colors will come true from seeds. In the case of *Primula Sinensis*, the garden *Cineraria*, and the Persian *Cyclamen* the colors generally are reproduced from seeds, but I do not know of another instance where distinct species have been crossed for the progeny to be thus exactly reproduced. In the *Gladiolus*, *Begonia* and other genera seeds are of no value for purposes of propagation if the reproduction of the characters of the seed-bearer is desired.

those of size, and there are specimens in the Kew Herbarium of *P. involucrata* quite as large as his plant. The dimensions of this are: Breadth of tuft, twelve inches; length of leaf, including oblong blade, six inches; flower-stems, of which his plant produced ten, sixteen inches; umbels three to six flowered. It is a charming Primrose for a cosy corner of the rock garden.

**CALLISTEPHUS HORTENSIS**.—This is the plant popularly known as the China Aster, the *Aster Chinensis* of Linnæus. It was introduced into the Jardin des Plantes, Paris, from China, about a century ago. The many changes wrought in its character, amounting to racial distinctions almost, we owe chiefly to French breeders, first among whom we may mention Monsieur Vilmorin. The type had long ago disappeared from cultivation, and so far as I can gather, no colored picture of it existed, so that we knew little of the

Fig. 56.—*Spiræa arguta*.—See page 442.

Messrs. Veitch & Sons have now many new hybrids of this genus.

**PRIMULA TRAILLI**.—This is a form of *Primula involucrata* (Munroi), one of the many species of *Primula* found on the Himalaya, where it grows at an altitude of from 12,000 to 15,000 feet. Forms of it are also found in Europe, northern Asia and Arctic America. It is hardy at Kew and is remarkable for its tall scapes bearing nodding umbels of about half a dozen pure white, very fragrant flowers. A figure of the type will be found in Lindley's *Botanical Register*, 1846, t. 31. Mr. G. F. Wilson, who has lately raised, flowered and exhibited plants of *P. Trailli*, is of opinion that it differs specifically from *P. involucrata*, but the differences as set forth by him in *The Gardeners' Chronicle* this week, where his plant is figured, are only

character of the progenitor of the China Aster beyond what herbarium specimens showed. Now, however, thanks to a French missionary in China and Messrs. Vilmorin & Co., we have the type again in cultivation, and a batch of plants raised from seeds supplied by the latter and grown in a border at Kew reveal it as a plant of decided beauty, "far more elegant in habit and beautiful in flower than any China Aster I have ever seen," was the remark of a gardener-artist who saw the Kew plants. These formed an irregular group from twelve to eighteen inches high, branched freely and clothed with healthy dark green toothed leaves. The flowers were from three to five inches in diameter, with a broad yellow disc surrounded by a single row of broad strap-shaped ray florets, colored pale mauve. The charm of the flowers was in their elegant

pose, their singleness and pleasing colors. Unfortunately, the plants have not seeded at Kew, but probably they have done so in the nursery of Messrs. Vilmorin & Co. in the south of France. The original China Aster is as certain to find admirers as the single Dahlia and the single Chrysanthemum.

**CHRYSANTHEMUM NIPPONICUM.**—I recommended this new Japanese Daisy last year as a pot-plant to flower in winter. Some plants of it grown at Kew out-of-doors with the common Chrysanthemums have made compact bushes a foot high and are now bearing erect daisy-like flowers with yellow disc and white ray, each flower being three inches across.

**A MODEL NURSERY.**—The late Mr. Bause was one of the most successful breeders and growers of indoor plants in Europe. After having served some of the principal London nurserymen he started a nursery for himself at Norwood, near Sydenham, about fifteen years ago. He died two years ago and his nursery is now controlled by his son, a young man, but a worthy successor of his father. I saw his nursery a few days ago and was so struck by the order, cleanliness and first-class cultivation there that I venture to call it a model of what a plant factory should be. The plants grown are all tropical and the houses are span-shaped, of various lengths, fifteen feet wide, the sides three feet, the central ridge eight feet high. The stages are formed of slates resting on iron battens and these are covered with a thin layer of cocoa-fibre or cinders. There is a wide central, and two narrow side stages, the paths being two feet wide. Seven rows of four-inch hot-water pipes afford the necessary heat. The stages are packed with plants of various sizes, all in the most perfect health, while on the hot-water pipes are rows of shallow boxes containing Palm seeds. Mr. Bause's specialties are *Cocos Weddelliana*, *Geonoma gracilis*, *Kentia Fosteriana*, *Phoenix rupicola* and *Livistona Sinensis*. Of each of these he sells from ten to twenty thousand plants a year, mostly from two to three feet in height. The cultivation is so excellent that almost every Palm bears every leaf it has developed from the seed to its present three, four or five year old condition. "My customers would not stick to me if my plants were not as perfect as I can make them," said Mr. Bause. *Dracæna terminalis* and all the very best of the *Dracænas* of that section are grown in large numbers and in the most perfect manner, every leaf as clean, well formed and richly colored as possible. Mr. Bause, senior, raised nearly all the best of these *Dracænas* during the time when he was manager to the General Horticultural Company. *Crotons* are grown on an equally large scale and to the same degree of perfection. *Caladiums* are another specialty, Mr. Bause having raised a large number of beautiful seedlings, most of which have been sent out by Messrs. J. Veitch & Sons. *Nepenthes* are grown suspended from the roof in almost every house, perfect little plants in teak baskets, each bearing perhaps half a dozen matured leaves, from each of which hangs a large, well-colored pitcher. Mr. Bause grows all the best sorts, including such rarities as the true *N. sanguinea*, and even a plant or two of *N. Rajah*. I asked what special manure was used. "None," said Mr. Bause, "but we get the best soil we can and take special care as to the water, shading and ventilation." This is one of dozens of plant factories in the suburbs of London whose special function it is to grow the best plants in the best manner for the supply of the big nurseries.

London.

### Carnation Notes.

WE are now in the height of the Chrysanthemum season, and while these are at their best Carnations and other less showy flowers are liable to suffer some neglect. But though Chrysanthemums are supreme for a few weeks, Carnations, with proper attention, bloom satisfactorily during the whole year. Chrysanthemums are unquestionably the popular flower during part of October and November, but the public soon grows weary of them, and Carnations are assuredly

the flower of the masses and are a close rival of the rose in popularity.

The weather this autumn has been remarkably clear and warm and especially delightful during October. There have been but light frosts up to this time, and summer-flowering Carnations are still blooming quite freely, although these flowers, naturally, compare unfavorably with those now growing under glass. Few private places have special houses devoted entirely to Carnations. Chrysanthemums usually occupy some of the bench room at this time, and the temperature and atmospheric conditions have to be regulated to suit them. No particular harm is done to Carnations so early in the season by a slightly lower temperature; the nights are not yet sufficiently cool to render much fire-heat necessary, and as the houses become well warmed during the day Carnations open quite rapidly. The plants are now growing freely and the flower-stems are appearing abundantly on all varieties. No time should be lost in providing the plants with supports. We formerly tied up the plants loosely to wire rods held in position by wires drawn along the rows. While this system produced a neat effect, it had disadvantages. Some varieties of recumbent habit, like Daybreak, were difficult to tie, and unless the ties were loosened from time to time as the plant grew, many shoots near the centre became weak, spindling and almost blanched. A Carnation support which will give satisfaction to everybody has not yet been invented. All the air and light possible should reach every part of the plants. This is impossible when they are tied up in a bunch, as we too often see them, with a piece of white twine or raffia. We have just gone over our plants and cleaned them, and instead of staking them up have cut up a quantity of small-mesh wire netting (commonly called chicken wire) into strips eighteen inches wide, doubled this into an acute arch, and stood it between the rows, which extend across the bench. This keeps the plants from crowding each other and allows sunlight and air to strike between the rows. Stretches of wire may be drawn along the sides of the bench to hold up the shoots and prevent them falling over. As the season advances and the stronger stems appear stretches of white twine should be drawn a few inches apart from each side of the bench and crossed at right angles; this will support the flowers. One advantage of this system is that the pieces of netting can be lifted out at any time when it is desired to stir the ground lightly and clean the plants, and this method is also advantageous in watering, as a hose can be passed inside of the arched netting. As to neatness there can be no question, for the plants practically hide the netting from view.

Rust is still more or less prevalent, but it appears to give less concern to growers than when it made its appearance a few years ago. A moist atmosphere, crowded, unclean and unsupported plants and uneven temperature will cause this disease to spread rapidly. Overhead watering must be avoided, since the water does injury by lodging in the axils of the leaves, and washes off the bloom of the foliage provided by Nature as a protection against spores. On the other hand, a comparatively dry atmosphere, careful watering and ventilation, picking off dead, decaying and diseased leaves, and keeping the house perfectly clean, with no rubbish thrown under the benches, will all tend to keep rust in check. Some growers find a dusting of air-slacked lime keeps rust from spreading, and we have used this preventive with success. A syringing with the arsenical solution on badly affected plants once a week has proved beneficial. Probably the Carnation which has rust in the most virulent form this year is the fine yellow variety, *Eldorado*. It was attacked last year to some extent, but not sufficiently to impair its flowering qualities. This season our plants were so badly affected that we threw them away, and the stock of other growers in this vicinity is more rusty than usual. It is unfortunate that *Eldorado* should be the victim of this disease, for it is the best yellow Carnation we have ever grown. Such varieties as *Buttercup*, *Louise Poroeh*, *Goldfinch* and *Bouton d'Or* are not worthy to be included in the same class with it.

We are trying a few plants of the *Mayor Pingree* this season, sent out last spring by John Breitmayer & Sons, Detroit, Michigan. This proves to be a vigorous grower and throws up wonderfully strong flower-stems. The flowers thus far produced are large and of fine form. This is a promising variety which we shall watch with interest. William Scott, notwithstanding all that has been written about its failing popularity in the flower markets, is still planted as largely as ever by growers in this section. The variety which is to supersede it has yet to be introduced. Sorts like *Edna Craig* and *Grace Battles*, which were widely boomed before being sent out, are now never seen. *Madame Diaz Albertine* is almost altogether

discarded, William Scott being so much better. Bridesmaid is of little value, except when a few fine exhibition blooms are desired. Triumph, good in some parts of the west, has proved of no value as a persistent bloomer. Nicholson has had its day and appears quite run out. Rose Queen is only now and again met with. Abundance is a neat little plant for a side bench. Victor, one of the 1897 novelties, proves disappointing thus far. None of these varieties succeed except in certain localities, while William Scott seems to do equally well from the Atlantic to the Pacific, and is probably more extensively grown than all other varieties of its color. Among white varieties decidedly the best of the new sorts we have tried is Flora Hill, introduced by E. G. Hill & Co., Richmond, Indiana. The flowers are very large, freely produced and have a delightful odor. The plant is the most vigorous grower of any kind we have. Harrison's White, the so-called white William Scott, has proved disappointing; the flowers are few and of medium quality. Edith Foster is a very promising variety, with stiff stems and flowers of good size and form. Alaska is grown to some extent by commercial growers, but the small flowers do not usurp the place of those of Lizzie McGowan, which we still find to be the most prolific and best all-round white Carnation. This variety does not appear to be popular in the Boston market. The leading Carnation growers for that market seem unable to grow it successfully. In many New England cities hardly any other white variety is to be seen. Occasionally Mrs. Fisher is grown, and one cultivator in this vicinity has two houses devoted to it and refuses to grow any other kind. For summer flowering it is unapproached. Nivea, a slender-growing sort introduced by Mr. H. A. Cook, Shrewsbury, Massachusetts, is largely grown here this season, but it is not equal to some other sorts up to this time. F. Mangold is still the leading crimson. Meteor is generally discarded. Now and then a small planting of Sebec is seen; this is a good crimson Carnation and flowers finely outdoors in summer. It lacks a stiff stem, however, such as F. Mangold has. The new variety, Mrs. George M. Bradt, as seen in one of the houses of Mr. W. Nicholson, Framingham, Massachusetts, a few days ago, looked specially well; this is, without doubt, now the finest striped variety; the color is white, striped with scarlet. The flowers do not fade out as many of those on Helen Keller do, and it is far more prolific than Minnie Cook. Della Fox proved unpopular in the markets here last season and is generally discarded. Daybreak still holds its own as one of the most popular market varieties and continues to do well. Its habit of growth is not of the best, but no other kind has yet been sent out which will take its place. Maud Dean, white, with a blush centre, is a neat, compact-growing sort, but its color is not of the delicate shrimp pink color which gives Daybreak its popularity. A first-class scarlet is still needed. Morello is a promising kind, but I think not so good as Jubilee. We still raise Hector, although it is not by any means an ideal grower. Such small varieties as John's Scarlet, Portia and E. G. Hill continue to be the leading market sorts here, and will probably be so until a scarlet variety with the many virtues of William Scott or Lizzie McGowan is introduced. Portia is perhaps the oldest commercial variety, largely grown for cut flowers, now on the market, as it is the healthiest.

Taunton, Mass.

*William N. Craig.*

### The Storing of Bulbs.

**B**ULBOUS and tuberous-rooted plants are indispensable for the garden in summer, and each autumn the best method of storing the bulbs and tubers must be considered. A great number of these plants rest annually at this period, and unfortunately, the plants that are taken the best care of while growing are often sadly neglected when at rest. They are frequently put to one side after they have flowered, as if they did not need further attention until it is time to plant them. But it takes a bulb longer to recuperate after flowering than it does to produce a crop. Often the flower-stem and leaves may be found within the bulb seemingly ready to start and come into bloom in a few weeks; but months of preparation are necessary for this growth to be possible. The Hyacinth and Narcissus are instances. What are known as Holland bulbs are for the most part spring-flowering, and are now in a cool cellar buried in sand and ripening for planting. Most of the south African bulbs and others from various parts of the globe are inclined to take their rest at this time, fortunately, and we thus have a store to draw upon when winter and spring bulbs are past.

Amaryllis are steadily increasing in popularity. These plants

are admirably adapted to house decoration and are easy to cultivate. Our stock has become so large that it is each year more difficult to store it. A cellar is not suitable, for at this time these bulbs need light and warmth to mature them. Much of the foliage is yet green, indeed *A. aulica* and its offspring are evergreen. It is unwise to cut off the stems and leaves, and these must die naturally. When the bulbs are perfectly at rest they may be stored under the benches or on shelves in the greenhouse; care must be taken that they do not become dust-dry or soaked with water. Amaryllis are for the most part deciduous, but a few roots will remain through the winter, and these are a great aid to the production of strong flower-spikes if they are properly taken care of and not allowed to rot or dry off. We are now starting a few of the bulbs which have matured earliest for an early display, and at the beginning of the new year all will be started. The only way to make up a collection of Amaryllis is to raise them from seeds of a good strain. Seedlings, however, are evergreen until they have reached maturity; that is, at the beginning of the third winter after sowing the seeds they begin to lose their leaves and should be treated like the older bulbs.

Gloxinias are, perhaps, the most showy of summer-flowering bulbs and are grown in large numbers. They are slow to go to rest if well grown and not neglected after blooming. We hesitate to dry off Gloxinias even at this time if they show no signs of drying, but give moisture as long as it is necessary to support the leaves that are building up the bulb to greater dimensions and vigor. After Gloxinias are dried off it is preferable to store them in the pots they grew in during summer. We frequently have not room enough to keep them in this way and they are shaken out and stored in boxes, soil being sifted in between the bulbs. Tuberous Begonias are treated in exactly the same way. If they have been used out-of-doors and have been cut off by frost they must be lifted and laid in an airy place until the stems part readily from the bulb, and then they may be put away in boxes. Both Begonias and Gloxinias are apt to suffer from what is known as dry rot in winter. A little moisture should be supplied to keep the bulbs plump, and then many of the root fibres will survive the winter and be an advantage in spring. It is often said that a place where potatoes may be safely wintered is suitable for storing Begonias and Gloxinias. I prefer a place with a little more warmth; a minimum of forty-five degrees is advisable, and certainly not more than fifty degrees as a maximum for any length of time if it is desired to have a late summer display.

At this time we shake *Achimenes* out of the soil in which they grew and use the pans for other bulbs. These bulbs may be picked out of the soil, placed in dry sand and kept perfectly dry during the winter if stored on a cool bottom in a cool house. We take the precaution to put a board under the pots or moisture would be drawn up by capillary attraction sufficient to start them too early, or at an inconvenient time. Our last *Achimenes* are just going out of flower; we find that these plants flowering late in September are a pleasing feature in the cool house; in the hottest summer months the flowers wilt at midday and the display is then short-lived.

We grow a large number of Japan Lilies for summer decoration, mostly of the *L. speciosum* type, and these have just been cut down and put in a cellar. There are no more valuable plants for use in late summer. To have them late it is advisable to store the bulbs in a cellar where there is moderate freezing. This will keep them dormant until it is safe to put them outdoors. If stored in a cellar that is frost-proof they will certainly start to grow before it is safe to have them outside, and in a glass structure their flowering period is hastened at least a month, and they will not last until the Japanese *Anemones* come in to take their place.

*Nerides* are valuable autumn plants and would, no doubt, be seen oftener if they did not take up so much valuable space in winter. As they flower first and then produce foliage they need care now. It is a mistake to repot them before they bloom, as we have found to our cost, but it may be safely done now. If it is not desired to increase the stock all the young bulbs may be taken off and thrown away. The point is to take the strain of support from the flowering bulbs or the display will be poor the next season. They should be potted according to their size, five or six bulbs in each pot. They should not again be disturbed for two years. With this treatment we have had a fine display this fall, and a good growth is now being encouraged.

Where summer decoration is required few plants lend themselves more kindly than the ornamental-leaved *Caladiums*. The set of Brazilian sorts shown at Chicago in 1893 has greatly increased the popularity of these plants, and they are becom-

ing better known each year. These are truly tropical bulbs, coming from under the equator, and cold is fatal to them, even for a short period. They must never be stored in a place where the temperature falls below fifty degrees, but above this degree of temperature there seems to be no limit. A friend winters his *Caladium*-bulbs on the pipes in a house where tropical Palms are grown; they are stored in the pots and soil in which they grew. A better plan is to shake out the bulbs at this time if the leaves have died off, and after cleaning off all decayed particles that are sometimes found at the base of the tubers, they should be placed in dry sand, new labels written for them, and stored in the boiler-cellar, as it is generally warm there. If decay is seen to have penetrated the tissues of the tuber, this must be cut away and some dry charcoal-dust mixed with a little sulphur be placed directly under the cut and filled round with sand. There will be no danger of losing valuable kinds if the bulbs are attended to in time. The newer English dwarf kinds are, without doubt, among the finest achievements of the hybridizers' skill, and reflect great credit on the raiser and distributors. Unfortunately, their price is almost prohibitory; but we have noticed that these highly-colored varieties are slow to increase, their vigor in this direction being dependent on the amount of green coloring matter contained in the leaves.

*Gladioli*, *Acidantheras*, *Tritonias* and *Montbretias* are all of the same nature from a cultivator's standpoint. They should be lifted in autumn as soon as frosts have killed off the tops. The new bulbs are then cleaned free of old roots and the old bulb that adheres to the base of the new one. After being laid out to dry for a few days in an airy dry place they are best kept in strong paper bags such as Holland bulbs come in. These should be suspended in a dry cool cellar free from frost. If care has been taken to free them from moisture they can be safely left until the next midsummer for the latest planting. We separate *Gladiolus*-bulbs into two sizes, many of the largest being set apart for early use in pots. These are started in the greenhouse soon after January, and flower in the pots in May, being planted out in the border to mature. Some of the largest bulbs are also kept for late planting. Cultivators of large quantities of *Gladioli*-bulbs find that the best way to winter their stock is to suspend it in a cellar as already described, except that when many bulbs are stored coarse bags are used, so as to admit air and let the moisture escape. If the bulbs are moist root-action will begin long before planting-time, and the contents of the bags will be a mass of roots that must be broken to separate the bulbs.

This year we have planted out our *Gloriosas*. They promise to be of more value outdoors than in the greenhouse, as their liability to insects in heat makes it difficult to succeed with them. When planted out there is no trouble of this sort and they flower freely. They may be lifted and stored like the *Caladiums* after frost has killed them back. It will be found best to start them in heat to bring them forward, or they are likely to remain in the soil half the summer before they begin to grow. Both *Gloriosa superba* and *G. Plantii* give satisfaction when used in this way.

*Dahlias* and *Cannas* may be stored in a frostproof cellar. *Cannas* must be placed on a perfectly dry bottom and most of the earth shaken out, or decay from moisture will follow. We once lost our whole collection from this cause. *Cannas* really need a little warmth to do them justice, especially the newer ones, as they seem to have a tendency to be evergreen. *Cannas* will also winter perfectly under the benches in a cool greenhouse if boards are placed under the roots. If they are moist they will start to grow before the proper time, and too much space is taken up in the houses when it can least be given. We prefer dry storage in a cellar that would be considered warm.

South Lancaster, Mass.

The Forest.

Natural Reforestation on the Mountains of Northern Colorado.—II.

IN noting the conditions that seem favorable to the starting and development of new forest growth, I have frequently seen confirmation of the often repeated and generally accepted statement that north slopes are more quickly covered by new growth than southern. There are occasional exceptions, however. The reason for the difference of growth on the slopes rests, apparently, in the more vigorous action of the sun upon the south slope; the nearly perpendicular rays melt the winter snows,

exhaust the soil moisture and parch the vegetation very quickly. Differences in the two slopes are apparent even at the time of burning, and, owing to the greater dryness, vegetation on the south slope will burn more completely. On the north slope the tangle of unconsumed remnants serves as a protection to the young growth and nurses it beyond the critical stage, while on the south slope the young plants, unprotected from the fierce rays of the sun, succumb quickly, and the slope remains barren.

In the lower mountains, at from 7,000 to 8,000 feet, there are several large and a greater number of smaller bodies of young timber that are attractive. The species is almost exclusively *Pinus contorta*, var. *Murrayana*, the Lodge Pole Pine. The trees stand thickly together, and the main body of any particular group as seen from a little distance will show a height of from fifteen to twenty feet. Penetrating to the interior of any of these bodies of timber we find that the trees, now green and vigorous, constitute but a small proportion of those that started in the race. The first growth of seedlings must have been very thick, and it seems from observations made that seed continued to germinate for several years after the main body started. Here are found the remains of thousands of young trees that, starved out by their more vigorous neighbors, have died and are slowly returning to the earth from which they came.

Well in from the border of one of these forests, in a spot where Nature's methods had met with no interference, I chose four trees to represent the best development of the forest, not taking the largest, but such as represented the largest number of thrifty trees. The average of these equaled a tree nineteen feet high, 3.8 inches in diameter at the ground, and fifty-two years old, as ascertained from a count of the annual rings. The rate of growth of this average tree for the first fifty years would be as follows:

	Diameter. Inches.	Gain in diameter by decades. Inches.	Percentage of gain by decades.	Percentage of whole by decades.
At ten years, . . .	1.			27.6
At twenty years, .	2.	1.	100.	55.2
At thirty years, .	2.69	.69	34.5	74.3
At forty years, .	3.19	.5	18.5	88.1
At fifty years, . .	3.62	.43	13.4	

One other tree was taken at this point, chosen for the smallest diameter in proportion to the height. It measured eleven feet eight inches high, was one inch in diameter at the ground, and was by the annual rings thirty-five years old.

Its development by decades was as follows:

	Diameter. Inches.	Gain in diameter by decades. Inches.	Percentage of gain by decades.	Percentage of whole by decades.
At ten years, . . .	.25			28.6
At twenty years, .	.59	.34	137.5	67.8
At thirty years, .	.87	.28	47.4	

A further observation in this forest, bearing on the thickness of seedlings, and the dying away from starvation, was as follows: From a ground space six inches square grew six trees. The largest was ten feet eight inches high, and 1.38 inches in diameter at the ground, apparently thrifty and vigorous. The next smaller was six feet six inches high, and .75 inches in diameter at the ground. This tree was living, but was plainly less vigorous than the larger one. The next smaller was four feet eight inches high, and .50 inches in diameter at the ground, and was dead. The next smaller was three feet six inches high, and .50 inches in diameter at the ground, living, but weak, and evidently growing weaker, as indicated by the yearly growth. The next was dead and had been broken off at three feet above

the ground. The diameter at the ground was .50 inches. The sixth tree was dead, two feet high, and .25 inches in diameter at the ground.

The areas of young forest here spoken of offer splendid opportunities for the spread of fires when once started, and there is abundant evidence that many such tracts have been entirely destroyed. Timber bodies that have been partially burned are common, and in a few places I have noted evidences, living or dead, of three generations. In one locality examined, the ground under the new growth was thickly covered with the rotting trunks of young trees, and the average of several counts made of the rings of these dead sticks indicated an age of thirty-two years at the time of burning. This would point to 1878 as the probable year when the last fire occurred there. The new growth averaged twelve years, so that in this case six years would appear to have elapsed between the burning and the germination of the seeds in the ground. Four specimens, chosen as being the smallest cone-bearing trees present, gave figures as follows :

	Height. Inches.	Diameter at ground. Inches.	Annual rings.
No. 1, . . . . .	18	.35	12
No. 2, . . . . .	14	.40	12
No. 3, . . . . .	17	.35	10
No. 4, . . . . .	17	.35	12

The starting of new growth has here been tardy and scanty. The scattering living trees are from twelve to fifteen years old, and I should place the date of burning as at least twenty-five years ago.

Natural processes for reclothing these denuded areas appear from our observations to be very slow ; but, unmolested, the task would in time be accomplished. The trouble seems to be that the destructive agency of fire, let loose by the carelessness or viciousness of man, tears down rather faster than Nature can build up, so that, instead of advancing toward a more extended forest area there is a constant retrograde movement. Fires of greater or less magnitude occur every year, and it seems likely to be a matter of a comparatively few years when the whole region, except in much-favored spots, will be stripped of its forests.

Colorado Agricultural College. Charles S. Crandall.

Exhibitions.

Chrysanthemums in Boston.

UNFAVORABLE weather during the early part of last week, at the time of the opening of the Chrysanthemum Show in Boston, somewhat lessened the number of exhibits. The two halls were well filled, however, without the usual crowding, and the exhibits were thus placed to good advantage. The size of pots for specimen plants was limited to ten inches, and the specimens were smaller than in former years. This is a step in the right direction, and all plants were uniformly well grown, more even in size than heretofore, and none were of abnormal size. The prizes for plants in pots were about equally divided between Mrs. B. P. Cheney and N. T. Kidder, Esq., and in some instances it was difficult to decide which really excelled. Mr. Kidder secured first prize in the class of twelve plants, and Mrs. Cheney was awarded first honors in most of the other classes. Prizes for plants were also awarded to Mrs. A. W. Blake, for twelve different varieties grown to one stem and one bloom ; to James L. Little, Esq., and to Dr. C. G. Weld.

The class of plants with a single flower, grown in a six-inch pot, was well contested this year. A number of exhibitors showed excellent flowers on dwarf plants, such as are specially useful for decorative purposes ; all the leading varieties were grown in this way, and were much admired.

The circular groups of Chrysanthemums, arranged for effect, attracted general attention. The group shown by Mrs. A. W. Blake was declared the best, and other exhibitors were Dr. C. G. Weld and J. L. Gardner, Esq. Foliage plants were used among the Chrysanthemums with admirable effect.

Messrs. E. M. Wood & Co., of Natick, had a striking exhibit of cut flowers in vases, ten blooms of one variety. The new Evangeline, white, was conspicuous, not only in this class, but was one of the most admired of all exhibits. The flowers were remarkable for purity of color and solid texture. Mrs. Perrine also showed to advantage. This is, without doubt, the purest pink chrysanthemum in commerce and was notably good in most collections in the exhibition. Messrs. Wood & Co. were also winners in the class of twenty-five blooms. David Nevins, a comparatively recent exhibitor, was among the winners in many classes, and his exhibits this year showed remarkable advance over those in former seasons. Cornelius Vanderbilt, Esq. (Mr. Robert Laurie, gardener), sent some remarkably good flowers from the gardens at Newport. The vase of Peter Kay, a new yellow incurved Chrysanthemum, similar to Major Bonnafon, won first premium as the best new yellow now in commerce. It was recently accorded 87 points in New York by the Chrysanthemum Society of America. A vase of Inter-Ocean, also shown by Mr. Laurie, won first honors among pink flowers. Joseph H. White, Esq., exhibited a new pink incurved flower which resembles Ada Spaulding, but is larger and of deeper color. It has been named Mrs. Gertrude Brydon. This was declared the best incurved Chrysanthemum not in commerce. H. McKay Twombly, Esq., Madison, New Jersey (Mr. A. Herrington, gardener), sent two fine vases of flowers. One of these contained blooms of Frank Hardy, the most sensational flower in the show ; these are very deep, the petals being creamy white and somewhat twisted. This novelty is of English origin, and, unlike most English Chrysanthemums, seems well adapted for cultivation here. Another good novelty was Pennsylvania, apparently a sport from Philadelphia, it being identical with that variety in shape, but a beautiful shade of clear yellow. It won a first-class certificate for the exhibitors, Hugh Graham & Son, of Philadelphia. Another notable seedling was a pink incurved Japanese flower shown by Mr. Frederick Cole, gardener to Arthur Hunnewell, Esq. A new primrose-yellow sport from Mrs. H. Robinson was shown by E. M. Wood & Co., of Natick ; this has been named Mrs. O. P. Bassett. But few incurved or anemone-flowered kinds were shown. Other winners of prizes for cut flowers were John Simpkins, Esq., Mrs. Cheney, E. S. Converse, Esq., James L. Little and Charles H. Souther.

A table of Orchids, tastefully arranged, was exhibited by Mr. J. S. Bailey. This comprised well-grown examples of Cattleya labiata, Oncidium Rogersii and a superb variety of Miltonia Morelana, called atro-rubens. The latter was awarded a certificate for its unusual depth and richness of color.

A creditable display of early-flowering Carnations was made by Mr. Nicholson, of Framingham, his vase of Mrs. George M. Bradt being the finest fancy variety shown ; it is similar to Helen Kellar, but superior to that fickle sort, and is, no doubt, the best fancy Carnation of that color. Mr. Peter Fisher also showed a new variety called Mrs. T. W. Lawson, a bright rose-pink. This is not yet in commerce, but has been tried for three years, and has proved its good qualities. It is altogether the brightest carnation in this color. Better names are needed for new Carnations ; the commemorative and descriptive titles are apt to be cumbersome, are soon abbreviated, and lose their original significance.

Gratuities were awarded for flowers to Mrs. E. M. Gill for chrysanthemums ; to William Nicholson for chrysanthemums and carnations. J. J. Van Alan, Esq. (Arthur Griffin, gardener), received a silver medal for the hybrid Begonia semperflorens. A first-class certificate was awarded to Peter Fisher for carnations. A. Roper received Honorable Mention for carnation Mayor Quincy, and Joseph Hilbert, Nyack, New York, for a sport of Swainsonia.

Notes.

Ben Davis apples, considered inferior here, seem to have won favor in Germany through their showy color and good-keeping qualities, and a sale of American fruit of this variety is reported to have realized \$6.01 a barrel, wholesale, on November 2d, in Hamburg.

Among the plants which assume brilliant coloring late in the autumn none equals, perhaps, our common high-bush Blueberry, Vaccinium corymbosum, which early in November lights up many northern swamp borders with its flaming foliage. The value of this Blueberry as a garden plant has been often insisted on in the columns of GARDEN and FOREST, but we cannot refrain from repeating that it is one of the most beautiful of all hardy shrubs. Beautiful in early spring with

its waxy-white bell-shaped flowers, beautiful in summer with its bright blue fruit, and especially beautiful now after the leaves have turned. It is a tall shrub and in good soil soon grows into a shapely specimen.

The change from northern-grown to southern fresh vegetables has gradually taken place in our markets, while the weather in this section is yet delightfully bright and mild, with hardly any suggestion of approaching winter. Peppers, cucumbers and the first tomatoes are now coming from fields in Florida. Eggplants and okra come from the same state, and green peas from Virginia. The supplies of string beans are received from Virginia and from North and South Carolina.

*Prunus subhirtella* is another Japanese Cherry which promises to become a valuable ornamental plant in our northern gardens. Like *Prunus pendula*, which it resembles also in the structure and size of the flowers, it blooms before the appearance of the leaves. In the Arnold Arboretum, where *Prunus subhirtella* has proved hardy and flowered abundantly for the last two or three years, it is now a broad bush with slender erect branches and ovate-acuminate dark green leaves from two to three inches in length. About the first of November these turn deep rich purple-red, making this plant a beautiful object at this season of the year. Altogether, *Prunus subhirtella* is one of the hardiest and most promising of the small trees recently introduced into our gardens. It was figured a year ago in *The Botanical Magazine* (t. 7508) from a plant sent in 1895 by the Arnold Arboretum to the Royal Gardens at Kew.

The two native species of dwarf *Pyrus*, or Choke-berries, *Pyrus nigra* and *Pyrus arbutifolia* (see GARDEN AND FOREST, vol. iii., p. 416, f. 52), are both good garden shrubs. At this season of the year, when the former has already lost its leaves, and its fruit, although still hanging on the branches, is much shrunken, *Pyrus arbutifolia* is the more attractive plant. It is a tall, slender bush with oblong or oblanceolate leaves, abundant white flowers which open about the 1st of June, and small fruits which do not ripen until the end of October, when they become bright scarlet and remain on the branches without loss of color or brilliancy until well into the winter. The leaves turn dark red about the time the fruit becomes ripe, and at this season this is one of the most attractive of our native shrubs. The habit is not as good as that of some others, but, in spite of this drawback, *Pyrus arbutifolia* may well find a place in any garden for the beauty of its autumn colors and the winter effects produced by its fruits.

Oranges from Louisiana and from Jamaica are now in this market, and the celebrated Indian River oranges, from Florida, are seen in considerable quantity for the first time since the ruinous freeze in that state in 1895. Several carloads of high-grade Florida oranges from the section about Arcadia have been forwarded to this city during the past few days. A carload of new-crop Navel oranges is already on the way from California to New York, having been started across the continent on November 6th, and is due here ten days later. It is said to be the first carload of this fruit shipped from that state this season. Besides Messina and Malaga lemons, from the Mediterranean, new-crop lemons of choice quality are arriving from California. Twenty-six carloads of so-called deciduous fruits, from California, were sold in this city last week. Grapes constituted almost the entire bulk, the principal varieties being Flame Tokay, Muscat, Cornichon, Verdell and Black Ferrera. Delaware and Niagara grapes, from Lake Keuka and more westerly parts of New York, are passing out of season, together with Concords. Keiffer, Beurre d'Anjou, Lawrence, Vicar of Wakefield, Beurre Bosc and Seckel pears, from near-by orchards, are still fairly plentiful, the latter costing more than twice as much as any of the other sorts.

In a paper read before the last meeting of the Society for the Promotion of Agricultural Science, on The Weights of Bees and the Loads they Carry, Professor Clarence P. Gillette, of the Colorado Agricultural College, reported that in his examinations of hundreds of pollen-bearing bees he had never found one heavily laden with honey, though these usually have a little honey, as do most working bees when leaving for the field. A carefully compiled table included in Professor Gillette's paper shows that the honey-carriers return to the hive a trifle more than one-half heavier than when they leave it, but the pollen-carriers, on an average, only increase their weight about one-tenth by the load they carry. The same table demonstrates that the bees from an issuing swarm are considerably heavier than bees coming to the hive laden with

honey, proving that they take as much food as possible with them when swarming, to guard against starvation before it is possible to again gather in stores for the new home. According to this table there are in one pound, on an average, 5,578 unloaded worker bees, and for the same weight 3,532 honey-laden bees are necessary. As many as 5,060 pollen-bearing bees or 5,447 unloaded pollen-bearers are required to weigh one pound, or 5,394 idlers; 2,206 drones; 10,965 loads of honey; or 40,580 loads of pollen, this amount representing the quantity of pollen carried on both legs by the bees.

In a recent number of *The Botanical Magazine*, Sir Joseph Hooker describes and figures (t. 7522) under the name of *Wistaria Chinensis*, var. *multijuga*, the *Wistaria* with long racemes which is so commonly cultivated in Japanese gardens and which has been grown in this country for the past twenty-five or thirty years. There is considerable confusion still with regard to the names of the Asiatic species of this genus; but this question need not be discussed here, and the object of this note is merely to call attention to a beautiful hardy vine which is not as well known as it should be. It differs from the ordinary *Wistaria Chinensis* in its narrower leaflets, much longer and looser racemes of very fragrant flowers and in their lateness, as the flowers of this plant open two or three weeks later than those of *Wistaria Chinensis*. In the autumn the two species can be readily distinguished, as the leaves of *Wistaria multijuga* turn clear yellow comparatively early, while those of *Wistaria Chinensis* remain green so late that they are almost invariably destroyed by frost before changing color. *Wistaria Chinensis* is a common Japanese forest plant and is also a native of China. *Wistaria multijuga* does not appear to be indigenous in Japan, and, judging from the fact that it is much hardier than *Wistaria Chinensis*, it probably came originally from northern China, and is one of those favorite garden plants of the Japanese introduced to them by the Buddhist priests. Whatever the right name for this handsome plant may be, it is evidently in every way entirely distinct from the common Japanese *Wistaria*, the plant universally cultivated in this country and Europe as *Wistaria Chinensis*.

In a paper on Thinning Fruit, recently read before the Hudson Valley Horticultural Society, Professor S. A. Beach gave an account of experiments in thinning fruit on Apple-trees. In the first experiment two heavily-fruited Baldwin trees were selected, and all the knotty, wormy and otherwise inferior fruit was picked off one of the trees, leaving but one fruit of a cluster. Of marketable fruit the thinned tree yielded nine and four-fifths per cent more first-grade, and four and one-half per cent less second-grade fruit than the unthinned tree. Six Baldwin and six Greening trees were used in the second experiment. Three trees of each kind were thinned by taking off all poor fruit and leaving the fruit on the trees at least four inches apart. The Baldwin trees which had been thinned gave twenty-six per cent less of marketable fruit, but twenty-two per cent more of it graded No. 1 than of the fruit from the unthinned Baldwins. Or, differently stated, although the unthinned trees carried above a fourth more fruit altogether, they actually each yielded one and a quarter bushels less No. 1 fruit than the thinned trees. With the Greenings this difference was even more marked, for the thinned Greening trees on an average produced two and one-quarter bushels more No. 1 fruit than the unthinned trees. Two trees of Hubbardston were used in the third test. On one tree the fruit was thinned to at least six inches apart. The thinned tree bore seventeen and four-tenths per cent more of No. 1 apples than the unthinned tree, and seventeen and one-tenth per cent less of No. 2 grade. In all these tests fewer apples dropped from the thinned trees, and their fruit was superior in quality and more highly colored, and was worth from ten to fifteen per cent more in market. The thinning and picking took about twice the time required for picking alone. The second method in these tests proved superior enough to the first to more than pay for the extra work involved; that is to say, the work paid best where it was thoroughly done. From the figures now at hand a satisfactory comparison of the second and third methods cannot be made, nor of the effect of thinning the fruit on the succeeding crop. In a season of an enormous crop, as in 1896, when many growers did not realize returns sufficient to cover the cost of packages and of picking and handling, thinning early in the season might be expected to decrease the yield of low-grade fruit and increase the amount of first grade, with a consequent advance in prices. Relieved of the drain of excessive bearing, the trees could ripen a fairly large crop of superior fruit, and better develop fruit-buds for the following year.

Wodenethe.

THIRTY years ago Wodenethe was a name well known to all Americans who loved gardens or were interested in the progress of American horticulture. Its history dates from 1840, when Mr. Henry Winthrop Sargent, a man of wealth and leisure, bought a country house on a plateau covered with White Oaks, Hickories and flowering Dogwoods on the east bank and somewhat above the Hudson River, nearly opposite the city of Newburg, and inspired and instructed by his neighbor, A. J. Downing, then at the height of his brilliant career, began to lay out a garden. This soon became distinguished in the art which heightened the natural beauties of the spot and the distant views obtained from it, and in its collections of exotic trees, especially of conifers, in which Mr. Sargent became deeply interested. To the late editions of Downing's *Theory and Practice of Landscape-gardening*—a work still without a rival in the English language—Mr. Sargent added a supplement in which is described the making of Wodenethe and the horticultural value and prospects of many of the trees which were first tested there in the United States. Mr. Sargent died fifteen years ago, but loving hands have preserved and increased the beauties of Wodenethe, which is still unsurpassed in its broad and lovely vistas, on the one hand stretching across the Hudson teaming with commerce to the hazy outlines of distant hills, and on the other to the nearer and bolder slopes and crags of the Fishkill Mountains.

Wodenethe, however, is no longer a trial ground for new trees. The limits of the usefulness of its twenty-two acres for work of this sort were reached many years ago, but the lessons which it can teach to-day are more valuable, perhaps, than at any previous time in its history, for at Wodenethe it is now possible to form a good idea of the true ability of many exotic trees to flourish in the northern and middle states. The hot dry summers and cold winters of the Hudson River Valley, the hungry soil, strongly impregnated with lime, and excessive overcrowding, sooner or later have destroyed most of the trees planted at Wodenethe, but some remain, and a brief mention of the most important may prove instructive to those who would plant exotic trees for the benefit of posterity.

To begin with the conifers, for in these Mr. Sargent was chiefly interested, *Pinus Strobus*, the White Pine of our eastern forests, easily surpasses its companions in height and in beauty of stem and crown, although the European Larch has grown nearly as tall and is in equally good health. Of many Norway Spruces only one is in presentable condition, and this begins to show that thinness of top which in this tree is a sure indication of decrepitude. The Oriental Spruce (*Picea orientalis*), although much younger and smaller than its European relative, is still vigorous and healthy, confirming the now generally accepted belief in the permanent value of this fine tree in our climate.

Of the *Abies* which have grown to a large size the most conspicuous and best preserved is the European *Abies pectinata*, represented by a good specimen fully seventy feet in height. A specimen of *Abies Cephalonica*, although badly crowded by its neighbors in a border plantation, shows that this tree is not only hardy in this climate, but may retain its beauty longer than many of the other Silver Firs. The Caucasian *Abies Nordmanniana* appears in several specimens from forty to fifty feet in height still densely clothed with branches and perfect in form and color. The west American *Abies concolor* is represented by a number of specimens which display several of the different forms of this tree. The largest individuals, which are from forty to fifty feet in height, have already passed the period of their greatest beauty and are thin in foliage and rather unhappy in appearance. Smaller plants, including the dark-leaved California form, known in England as *Abies Lowiana*, are still perfect. *Abies nobilis* has grown slowly and not very luxuriantly; appearing to be hardy, it gives little promise of attaining a large size.

The Scotch Pines have disappeared, but a single Austrian Pine, which, judging by its size, must have been one of the first trees planted by Mr. Sargent, has escaped the ordinary fate of this tree in the United States and is still in good health. The remarkable specimen of *Pinus ponderosa* with pendant branches (see *GARDEN AND FOREST*, vol. i., p. 392, f. 62) has suffered from the attacks of the fungus which generally prevents the successful cultivation of this tree in the eastern states, and is reduced to a few sparse branches at the top of a naked stem, while a smaller specimen of an ordinary long-leaved form of this Pine, about thirty years planted, begins to fail in the upper branches. There is no other California Pine left in the collection, nor any Asiatic representative of the genus, although most of the Californian and many of the Indian and Japanese species were planted by Mr. Sargent.

A good blue-leaved specimen of *Picea pungens*, raised from Dr. Parry's seeds collected in Colorado in 1862, is still in excellent condition and does not show yet the unfortunate tendency of this tree to lose its lowest branches. Two specimens of the Cedar of Lebanon, showing in stunted and contorted stems the evidences of a long struggle against adverse conditions, have now commenced to grow upward, and seem destined to long life. *Cupressus Lawsoniana* appears in two or three healthy, handsome plants. *Retinosporas*, on the whole, have done well, although the summer climate at Wodenethe is too dry for them, and there are in the collection a number of good plants of *R. filifera* and of *R. pisifera aurea*. Many specimens of *Biota* in different forms show the power of the Chinese *Arbor-vitæ* to adapt itself to our climate; and small plants of *Sciadopitys* and of *Tsuga Sieboldii*, from twenty to twenty-five years old, testify to the hardiness of these Japanese trees in this climate. Of the hundreds or perhaps thousands of conifers planted by Mr. Sargent during the years of his greatest activity, when he ransacked every nursery in Europe for species and abnormal forms, those which we have mentioned are now the only ones which are conspicuous for their size and healthy condition.

The Yew family has, on the whole, done better at Wodenethe than the true conifers. A *Ginkgo* just beginning to emerge from its juvenile form promises to become a long-lived and large tree. The European Yew seems entirely

at home at Wodenethe, where there are a number of noble specimens with green and with yellow foliage in perfect health. The Torreyas have all disappeared, but *Cephalotaxus* is well represented by the Japanese *T. drupacea*, and by the Chinese *T. Fortunei*, which has grown into a low bushy tree of dense habit and brilliant foliage, and is now one of the most beautiful plants in the whole collection.

Of the exotic trees with deciduous leaves the most remarkable, perhaps, is a specimen of *Magnolia macrophylla*, a perfectly-balanced tree, about fifty feet high and fully fifty feet across the branches. The European Beech shows its value in our climate by large and healthy specimens of the Weeping and the Cut-leaved varieties. The yellow-flowered Buckeye (*Æsculus octandra*), a native of more southern forests, is perfectly at home at Wodenethe, as are the *Kœlreuteria*, the Yellow Wood, the European Linden (*T. platyphyllos*) and the *Gleditsia*. The form of our southern Bald Cypress (*Taxodium*), which in gardens usually passes as *Glyptostrobus pendulus*, has grown well and appears perfectly healthy, and large masses of the Chinese *Magnolias* show the permanent value of these trees in the northern states.

It has been seen that the list of exotic trees which, surviving at Wodenethe for more than forty years, have proved themselves really satisfactory there is not a long one. In the shortness of the list is to be found, however, the true significance and the real value of Mr. Sargent's dendrological experiments, which seem to show clearly that American trees are the best for America, and that the most permanent living ornaments of our parks and plantations must be sought in the American *silva*, with such foreign trees as experiments like that at Wodenethe may from time to time show to be long-lived in our climate.

MR. T. JEFFERSON COOLIDGE, of Boston, the treasurer of the Amoskeag Manufacturing Company at Manchester, New Hampshire, which is one of the largest companies of its kind in the world, calls attention, in his last report to his stockholders, for the second time to the present and increasing disposition of the Merrimac River, on which his company is largely dependent for its power, to run in the extremes of sudden freshets and very low water, caused, he believes, by the denudation of the hills and mountains about its sources. The whole question of preserving the forests in northern New Hampshire, and especially in the White Mountain region, is important and difficult. In this elevated region head many of the streams, which become the principal sources of power for mills in New Hampshire, Connecticut and Massachusetts, and their preservation would clearly benefit the manufacturing interests of New England. To its forests, too, the White Mountain region, which is the best summer sanitarium in the north-eastern states, owes its chief charm and principal attraction; and if the destruction of these forests is allowed to continue, the value of this whole region both as a source of water-supply and as a resort for summer tourists will be ruined. The people of New Hampshire might wisely follow the example set by this state and purchase the forest land covering the whole of the elevated region in the northern counties and hold it as a public forest; but the people of New Hampshire are poor, and public sentiment would hardly authorize at this time an expenditure of several million dollars for such a purpose. As a number of the streams which rise in this region flow through more than one state, the aid of the general Government might be invoked. The preservation of these forests, however, could be much more securely obtained by the intervention of private capital and the formation of a corporation to acquire and hold forest property under conditions which would insure a perpetual forest covering. The large corporations directly interested in the flow of these rivers might become stockholders in such a corporation and control its policy. The owners of summer resorts in the White Mountains who would be benefited by the preservation of these forests might find it for their interest

to subscribe to its stock, and doubtless individuals actuated by one motive or another might be willing to contribute to its success. A great forest property of this sort might, if economically managed, become fairly profitable in the future, and there is no reason to doubt that it might be made to pay small dividends almost from the beginning. The permanency of such property ought to influence investors, and the time is not far distant when certain annual returns of two or three per cent will seem attractive to conservative persons.

#### Notes on Cultivated Conifers.—VII.

**SCIADOPITYS**, which is the first genus of the *Taxodiaceæ* which we shall consider, is monotypic and remarkable in the character of its leaves which are deltoid in form, concave, minute, and simple in character, while the apparent leaves are phylloid shoots from the axils of the true leaves. The male flowers are collected in dense catkin-like heads at the ends of the branches, and the cones are erect on short lateral shoots. The genus is monotypic and endemic to Japan. Like the Ginkgo, *Sciadopitys* was for a long time known only from a few individuals cultivated in temple gardens and from a large grove on the hill in Kyushu, in the neighborhood of the ancient monastery-town of Koya. This grove was once supposed to be the original home of the species; it is more probable, however, that all these trees were planted many centuries ago. Dupont, a French engineer, found what he considered indigenous trees on Chimono and in the Province of Meno; and in this province, below Nakatsu-gawa, I found great numbers of *Sciadopitys* growing, as I thought, indigenously and sending up their narrow pyramidal heads far above the Pines and other forest trees. In a country, however, which has been densely populated for centuries, and where tree-planting has been a recognized industry for more than a thousand years, it is not always easy to determine whether what may appear to be a perfectly natural forest has not been planted. In these mountain forests of Meno the *Sciadopitys* grows with a tall, straight trunk to a height of nearly a hundred feet, and is always remarkable in its narrow compact pyramidal head of dark and lustrous foliage. This tree is so abundant here that the wood, which is nearly white and very strong and straight-grained, is a regular article of commerce, being floated down the Kisogawa in large rafts to Osaka, where it is chiefly consumed. Except in the immediate neighborhood of this Mono forest, *Sciadopitys* does not appear to be cultivated in Japan except in temple gardens, where specimens picturesque in old age, with loose habit and pendant branches, may occasionally be seen carefully protected by low stone railings.

*Sciadopitys verticellata*, which owes its common name of Umbrella Pine to the arrangement of the phylloid shoots near the ends of the branches after the fashion of the ribs of an umbrella, has been an inhabitant of our gardens for twenty-five or thirty years, and is perfectly hardy in the neighborhood of Boston and one of our most distinct and beautiful garden conifers. Although for several years it grows very slowly and is difficult to raise from seeds, the Umbrella Pine grows rapidly when it is once established, and at the end of twenty-five years may be expected to attain in good soil a height of eighteen or twenty feet, and for many years to retain the dense, compact pyramidal habit which is characteristic of this tree, except in very old age. There is a Japanese variety with shoots marked with yellow which is occasionally cultivated in gardens.

Of *Sequoia* and its two California species, the last remnants of a race which once abounded in the Arctic Circle and was widely spread over this continent and Europe, little need be said here. The Redwood (*Sequoia sempervirens*), the tallest of American trees, can only flourish where winters are mild and moisture abundant, and I have never seen a specimen on the Atlantic seaboard north of Charleston, South Carolina. The Big Tree, *Sequoia Wellingtonia*, is hardly more valuable for our plantations. A

small group of these trees, stunted in growth and forlorn in appearance, has lived for years at Rochester, New York, and there are a few unhappy specimens in the neighborhood of New York. The largest which I have heard of in the east is near West Chester, Pennsylvania. A few years ago a negro cut off the top for a Christmas-tree and ruined its symmetry. In favorable positions, therefore, in the middle, and possibly in the northern states, this Sequoia can sometimes be kept alive for many years, although it is only too evident that there will never be seen on this side of the continent the massive stems and dome-like heads of this crowning glory of the American forests.

*Cryptomeria* is another monotypic Japanese genus and is distinguished by spirally arranged heteromorphous leaves, terminal monœcious flowers and small globose cones ripening in one season, with bracts free and recurved above, and wedge-shaped obovate scales more or less deeply divided at the apex into sharply pointed lobes, each scale bearing from three to five erect, narrow-winged seeds.

Japan owes much of the beauty of its temple gardens to the *Cryptomeria*. Nowhere is there a more solemn and impressive grove of planted trees than that which surrounds the temples and tombs at Nikkō and which is almost entirely composed of the *Cryptomeria*, and nowhere is there a nobler avenue of conifers than that which leads to this last resting-place of the greatest of the Shoguns (see GARDEN AND FOREST, vol. vi., f. 66). The Sugi, as *Cryptomeria Japonica* is called in its native country, is the most generally planted timber-tree of the Empire and its wood is more generally used than that of any other conifer. It is one of the commonest trees in all temple gardens and in many roadside plantations, and sometimes rises to the height of one hundred and twenty-five feet, with a tall trunk tapering abruptly from a broad base, covered with bright cinnamon-red bark and crowned with an irregular conical dark green head; and in beauty and majesty of port has no rival except in the Sequoias of California. The wood of the Sugi is coarse-grained, with thick layers of annual growth, dark red heartwood and thick pale sapwood. Easily worked and strong and durable, it is employed in all sorts of construction. The bark, which is always carefully preserved when the trees are cut, is used to cover the roofs of houses. A bunch of the branchlets hung over a door indicates that Saké is sold within.

*Cryptomeria Japonica* does not really thrive in Europe or in the United States, and although it was first sent to Europe more than fifty years ago I have never seen a promising specimen of this tree outside of Japan. It is fairly hardy even in the neighborhood of Boston in sheltered and well-protected positions, but never looks truly happy in regions which might be supposed to be much better suited to it than eastern Massachusetts, like the south Atlantic states, southern England, and the Italian lakes, a district where nearly all conifers grow more freely probably than in any other part of Europe.

There are a number of forms of *Cryptomeria Japonica* of Japanese origin in cultivation. The most distinct of these (var. *elegans*) is a form with scattered spreading leaves which during the spring and summer are bright green and in the autumn become red-bronze color. It is a small compact tree furnished with short horizontal branches and pendulous branchlets, and is less hardy here than the ordinary form. *Cryptomeria Japonica Lobbi* is rather more compact in habit than the ordinary *Cryptomeria Japonica*; the branches are less pendulous and the foliage rather darker green. It is said to have reached Europe from the Botanic Garden at Buitenzorg, to which it had been sent by Siebold from Japan. *Cryptomeria Japonica nana* is a small bushy shrub rarely exceeding two feet in height, and in *Cryptomeria Japonica spiralis* the leaves are closely appressed against the branches. There is a form (var. *argentea*) in which the young growth is silvery white.

*Taxodium*, the Bald Cypress, which was once common and widely distributed in the Arctic Circle, and during Miocene and Pliocene times was spread over the interior

of this continent, and over Europe and north-eastern Siberia, has now become reduced to one or possibly two species confined to the southern United States and Mexico. The genus is distinguished by its paniced male flowers; by the form of the spirally disposed cone-scales, which are abruptly dilated from slender stipes into irregular four-sided thin discs conspicuously marked when half-grown with the reflexed tips of the flower-scales, and at maturity are often mucronulate; by its three-winged seeds, deciduous, dimorphous foliage, and by the remarkably woody projections, the so-called Cypress knees, which rise from the roots to above the surface of the shallow water in which this tree grows to its greatest perfection.

The pride of our southern coast forests, and one of the largest and most valuable timber-trees in the world, *Taxodium distichum*, in spite of its semiaquatic habit and southern home, has proved a first-rate park and garden tree, showing the vigor of its constitution in its ability to flourish when transplanted to dry ground in climates of severe winter cold and summer drought, like that of eastern Massachusetts, where several specimens have been growing for seventy or eighty years. Up to the present time, however, the Bald Cypress has retained in cultivation its rather formal pyramidal habit, and I have never seen a cultivated tree which showed any indication of assuming the mature form with low, broad, flat crown of wide-spreading branches which distinguishes this tree in its native river swamps, and which, raised high above dark waters on its stately buttressed trunk, makes it one of the most majestic and impressive trees of our forests. There is a form of the Bald Cypress in gardens with pendulous branches (var. *pendula*) which is a distinct and handsome plant, and European nurserymen propagate dwarf forms and others of more or less abnormal habit.

The tree which in the United States and Europe is almost universally called *Glyptostrobus pendulus*, is really a juvenile form of the *Taxodium* of the southern states, *Glyptostrobus*, being a south China genus with a single species, which has possibly never been brought to the United States, and which would not be hardy in this part of the country. In this form the slender branchlets, which are pendulous or erect, are often six or seven inches in length, and are covered with closely appressed acicular leaves, and no one unfamiliar with the fact that normal branchlets with distichous leaves sometimes appear would imagine that it was a form of the Bald Cypress. This acerose form is not uncommon in South Carolina, in northern Florida and in the neighborhood of Mobile, Alabama. It is a comparatively small tree in its native swamps, and, in spite of its southern home, is hardy in New England, where it is one of the most distinct and beautiful of the pyramidal conifers. The proper name for this tree is *Taxodium distichum*, var. *imbricarium*.

The Mexican Bald Cypress, *Taxodium mucronulatum*, which was first distinguished from the tree of the southern states by an Italian botanist who studied a cultivated plant in the Botanic Garden at Naples, is possibly a distinct species, although when more thoroughly known it may prove to be a mere geographical form of our tree. It is chiefly known from a few very large and venerable individuals which have filled travelers in Mexico with admiration since the time of the Spanish conquest. The largest of these trees of which authentic measurements are recorded stands in the town of Tule, on the road from Ozaca to Guatemala. A portrait of this tree was published on page 125 of the current volume of GARDEN AND FOREST (fig. 15); in the third volume (fig. 28) is a portrait of the Cypress of Montezuma, which is the largest of the Cypress-trees in the gardens of Chapultepec. This was a noted tree four centuries ago, and is 170 feet high, with a trunk from forty to nearly fifty feet in circumference. It is believed to be at least 700 years old.

The Abietinæ as garden plants, beginning in the next issue with *Pinus*, will be discussed in the remaining numbers of these notes.

## Horticultural Tombstones.

ONE of the pictures which lingers in my mind after a visit in northern Pennsylvania during the past summer is that of an old Pear-tree standing alone in a meadow. Its top was partially dead, and the rest of the tree was fighting a losing battle with that dreaded enemy of the Pear, fire-blight. There is, perhaps, nothing peculiarly worthy of note in such a picture as this, but the tree presents the last vestige of an unwritten history. It is a relic of one of those visionary ventures which so often end in disappointment and loss. Here, in times past, lived a farmer, who was something of a character in his way. This is but one of the fading traces which tell of ventures in different lines. On the stream just above are still to be seen evidences of an old milldam, which supplied the motive power for a sawmill in the olden days. This in itself might well serve as a basis for moralizing, for here, where once the waiting logs and piles of lumber told of many days of slow but steady work, the denuded hills now look down upon a stream robbed of its strength, except as manifested in an occasional fit of frenzy in which it far surpasses its old-time vigor, only to quickly relapse again into a lifeless condition and sometimes even entirely to disappear.

A short distance below the old milldam starts a now dry and grass-covered race which led the water to another and a smaller dam where a horizontal wheel with a tall and upright shaft furnished the power to run a stave-saw, a drag-saw for sawing wood, and perhaps one or two other small pieces of machinery. The building with which these were connected was primarily a cooper shop. From the opposite side of the old milldam a small overshot wheel, ingeniously connected with wires which played back and forth, did the churning at the house some fifty rods away.

A little way from the milldam, in the same field with the Pear-tree, is the site of an abandoned oil-well, which was expected to make the owner of the farm wealthy and to furnish the inhabitants of the community with unstinted light, but which, unfortunately, only gave out in the morning the oil which had been poured in at night by others while the owner slept. All these are within a quarter of a mile of each other. Across the highway, on the same farm, may be seen the traces of an old brick kiln, which evidently met the same fate as the other ventures, perhaps even before they had their birth. Yet primarily this man was a farmer and made the business pay, leaving his farm and home intact when, as an old man, he passed away.

But the epitaph upon the Pear-tree is the one I wish to interpret. Here, in days gone, was something of a Pear orchard, of which this tree is the lone survivor. In the height of its glory the orchard covered something like an acre of ground. If memory serves me rightly, most of the trees were dwarfs, but my earliest recollection only recalls the orchard as badly thinned by blight and other fatal enemies. At one end of the fenced-in field was a clump of Lawton Blackberries, which served mainly as a temptation and a vexation to the barefoot boy who passed that way.

Doubtless the owner of this orchard had read or heard of the success of some trained fruit grower with Pears, and had visions of success for himself which were never realized. Any one familiar with country life can call to mind numerous examples of a similar sort, and the same characteristic of human nature manifests itself just as frequently, though in slightly different ways, in commercial life. The broadest lesson to be derived from it is a lesson on the frailty of human judgment, but the lesson of most interest to the horticulturist is the lesson of changed conditions. There may have been a time when such a venture would have paid in a favorable locality, but if so, that time has long since passed. The successful and thrifty farmer of the olden time was the one who could most nearly provide for all his wants in the products of his own farm. He not only produced the meat, the grain, the vegetables, the fruits and the condiments which furnished the food for his family,

but also the wool and the flax which were to provide the clothing, these in turn being fitted and transformed into the form in which they were needed without the aid of capitalist, factory or employee, as we now understand these terms. Gradually this field of production has been narrowing. Another and another of the comforts and luxuries of life have been found to be more conveniently and cheaply furnished from an outside source. Sometimes even yet the farmer most commended is the one who has some minor product to count upon which can be exchanged for things he wishes to purchase. Yet this method is just as certainly and as surely passing out of date as has the primitive one of producing everything at home. Whether wisely or not is open to argument, but to fight against it is only to fight the incoming tide of the world's progress. The cost of production must be reduced to a lower point than can be done in the cultivation of a little of one crop or another by a man who has no special knowledge of the needs of the crop and no special facilities or conditions in its favor.

Granting that the farmer already referred to knew how or could have learned how to grow Pears as well as any one else, his three-quarters of an acre could not be a success to-day. The supply would be too great for the local village market and too small to be profitably placed in a large market. The cost of seeking a buyer, of packing and of shipping would all be far greater in proportion than with a larger product, while the amount would be too small to attract any attention from buyers. Yet the most important reason of all doubtless lies in the fact that the man must be trained for his work. This law is just as inevitable in horticulture as in commerce or professional life. Success in any line demands study and a complete mastery of details. This the man who attempts to produce a multitude of things cannot acquire. This old Pear orchard has failed and passed into oblivion, not from any lack of adaptability of the Pear to that locality, for Pear-trees in the vicinity are loaded with fruit year after year, and seldom fail to fruit from any cause. But because it was a venture not backed up by the knowledge and training which could have made it succeed.

University of Nebraska, Lincoln, Neb.

Fred W. Card.

## New or Little-known Plants.

*Hypericum lobocarpum*.

TWO weeks ago we published a figure of *Hypericum galioides*, a plant which is now well established in our gardens, and on page 453 of the present issue appears a figure of a less well-known species, *Hypericum lobocarpum*, still to be introduced into cultivation.

*Hypericum lobocarpum*\* is described as a shrub with upright stems from five to seven feet in height, linear-lanceolate or narrow oblong leaves from one to three inches in length, numerous flowers, somewhat smaller than those of *Hypericum densiflorum*, and stoutly beaked five-celled, deeply five-lobed fruits, the carpels being nearly distinct and falling away separately from the central axis.

*Hypericum lobocarpum* inhabits Oak barrens of middle and western Tennessee, western Mississippi and southern Louisiana, and, judging by other species of this genus from the same general region, may be expected to prove hardy in northern gardens.

*CRATÆGUS CORDATA*.—Fifty years ago this so-called Washington Thorn was more frequently seen in our gardens than it is to-day, although it is one of the most beautiful of the hardy small trees available for our plantations. It is very hardy; it flowers later than the other species and its flowers are produced in great profusion. These are followed by small showy orange-colored fruits, which hang on the branches until winter, and in November, after the foliage of most native plants has fallen, the lustrous leaves

\*Coulter, *Gray Syn. Fl. N. Am.*, i., pt. i., 285 (1897).

Fig. 57.—*Hypericum lobocarpum*.—See page 452.

1. Portion of a plant, natural size.    2. Fruit, natural size.    3. Cross-section of a fruit, enlarged.

turn bright orange-color and make a delightful contrast with the darker fruits. This is such a clean, hardy, well-behaved plant and so entirely free from the attacks of insects and fungal diseases that it ought to be one of the

most popular of our native trees for general park planting. Hardly less beautiful at this season of the year is *Crataegus viridis*. This is one of the largest of the American Hawthorns, and a southern species. It has, however, proved

hardy in the Arnold Arboretum, where there are now a number of large plants which during the first week of November were brilliant with their orange and scarlet foliage and small bright red fruits.

**CRATÆGUS CARRIERI.**—Two years ago we called attention (vol. viii., p. 495) to the beauty of the fruit of this tree. It is valuable, too, for the splendid orange and scarlet tints of its leaves, which make a delightful contrast at this season with the large oblong bright scarlet, lustrous haws, which hang on the branches long after the leaves fall and well into the winter. This interesting tree originated in the Jardin des Plantes in Paris, where it was raised, it has been said, from a seed of *Cratægus Mexicana*. More probably it is a hybrid of *Cratægus Crus-Galli*, which it resembles in many characters, and of some species not easily determined. Whatever its origin may have been, however, this is a perfectly hardy tree of good habit, and in the autumn it is unsurpassed in beauty of foliage and fruit. Altogether, it is one of the most desirable of the whole genus for the north, and a plant of first-rate merit.

**TWO CHINESE TREES.**—Two little-known north China plants in the Arnold Arboretum were conspicuous during the first week in November from the brilliant coloring of their leaves. The Chinese variety of the Mountain Ash, the *Sorbus discolor* of Maximowicz, retains its leaves much longer than any other Mountain Ash in our gardens, and, unlike those of the other species, the leaves turn deep dark purple-red before falling, making it a distinct and very attractive autumn plant. *Cratægus pinnatifida*, sometimes cultivated in China for its edible fruit and distinguished by its deeply divided leaves, is conspicuous in the autumn from the brilliant orange and scarlet tints of its foliage. A perfectly hardy small tree, this promises to be an important addition to plants of this class.

## Cultural Department.

### Chrysanthemum Novelties of 1897.

THE best very early white Chrysanthemum for commercial purposes I have ever seen is Midge. The plant is but twelve to fifteen inches high, needs no staking, and makes an ideal pot-plant. The foliage is beautiful in form and is carried down to the base and well up to the flower. The leaves are dark green, almost black, and make a bold contrast with the pure white flowers of the snowball type. Flowers were ready to cut October 4th, and some of the first flowers are still crisp and altogether salable. Midge is claimed by the introducer to be a fuller flower and better in every way than the flowers of Madame F. Bergmann. This is an important claim, for there is no early variety about which there is such general agreement as Madame F. Bergmann, except among the yellows, where Marion Henderson is the general favorite. We have not grown Madame F. Bergmann this year under the same conditions as we have grown Midge, but in dwarfness, fullness and keeping qualities we believe Midge is superior. On the whole, Midge is the greatest improvement of the year.

A second early white of the same snowball type, and a worthy successor of Midge, is the new variety, George S. Kalb. Like Midge, the flowers are only medium-sized, but this is no objection, as they are too early for the shows, and large flowers are not so necessary by October 10th. This variety also gives a succession of flowers, some of which are salable as late as November 10th, and there seems to be no reason why it should not produce ten flowers as well as four.

I see no improvement in the midseason white Chrysanthemums. Western King with us is distinctly inferior to Mrs. Henry Robinson. The numerous late varieties are commonplace, except Mrs. Martin A. Ryerson; this promises to be a worthy predecessor of Yanoma, which ends the succession of whites.

The yellow varieties have not advanced at all. There is nothing equal to last year's Modesto, Duchess of York, W. S. Devis, Mrs. C. B. Freeman, or Buff Globe, all of which represent different types. Sunstone, however, is entirely perfect within its limitations of color, and may be safely commended to those who do not appreciate the fading out of Philadelphia. Maud Adams is an unusual type, if not a wholly new one, but its strange, stiff, tubular florets, with their indescribable form and carriage, mark it as a curiosity for fanciers. It is not a

variety like Modesto, which amateur and professional cultivators would both wish to grow, and which is suitable for exhibition, for cut flowers and for pot-culture. Indeed, it rarely occurs that a variety is suitable for all these purposes. Such an exception, however, is Casco, which seems to be a decided improvement among the dark sorts. Although it is properly classed with Chrysanthemums in the early section, it lasts well through the midseason. It belongs to that large group called by the English Amaranths. The reverse of the florets in these sorts is always lighter than the face, sometimes bright and silvery, often dull neutral shades, evidently derived from the face, as though they were stained through. The dull reverse is the chief feature of Casco, but the florets are relaxed enough to give a suggestion of the rich garnet within. Leonidas is a large flower of the Amaranth class. It is early and long-keeping, with a bold and rugged, almost bristling, form. This, too, is a decided advance.

I see no improvement among the bronzes or reds except in Loantika, which might be classed in either group. It resembles Pluto, which is by far the best red with a yellow reverse we have yet seen, not even excepting Charles Davis, which still seems to be the commercial favorite. Loantika is an early sort, and ends just as Pluto is well started on its interesting and daily changing development. There is no late variety yet to complete this succession.

The pink sorts have received two notable additions this season. There has never been as satisfactory an early pink variety as is Marion Henderson among the yellow-flowering kinds. Last year a superior pink Chrysanthemum seemed to be attained in Glory of the Pacific, although the variety with us was an utter failure, being so far "off character" as to be practically not true to name. Elvena is the best early light pink of its form we have seen, and lasted seventeen days before the yellow disc appeared, and ended its salable condition. There is no improvement in the midseason pinks, Mrs. Perrin and Madame Felix Perrin of last year (these are practically the same) being the best rosy pink varieties yet attained for all-around use, though still far from ideal as regards evenness of color. Several others advertised as pink are capital whites, but fourteen out of thirty-one varieties grown under the same, and otherwise successful, conditions have shown only a trace of pink at most. Merula might be classed among the light pinks. It is badly lined at first, but at its best the mass effect is dainty in color and loose in form, although very dense and full and round like Ophir and others which are close to the Chinese type, but not quite regular and formal enough to be included by the English in their Incurred section.

Among the less familiar sections, such as the large-flowered varieties and the Japanese Anemones, I see no improvement; but there is one single variety, Mizpah, worth serious consideration. This is a plant from twelve to fifteen inches high, ideal for pot-culture. A plant of this variety, with eighty or more crimson flowers, proved one of the greatest attractions to our visitors. It probably originated from *C. frutescens*, the same species to which the Paris Daisy or Marguerite belongs, but may be used as a rough illustration of the long way our cultivated Japanese Chrysanthemums have come from a primitive form. Mizpah has two or three series of rays, but is single in effect. Of course, the florets have not the brilliant color and velvety finish of a Cineraria, but for artistic decorative work the general effect is quite as good at this time of year. The only drawback to Mizpah is the fading of the color to a pinkish hue, when the yellow disc becomes inharmonious unless the flowers are picked off.

This view of the American novelties is fairly complete, as we have grown under the same conditions all but ten of the sixty-five varieties of American origin first described in the catalogues of 1897. The American introductions are not so numerous as the importations, but it is impossible to say when a variety of European, Australian or Japanese origin becomes a novelty in America, and it is impossible to grow them all. The Californian novelties are not considered in this account, as California is practically a foreign country to the eastern states in the matter of novelties. Judging by the thirty seedlings sent to the Cornell Experiment Station in advance of the trade, there is more of promise in 1898 than in 1897 for advances in American novelties.

Ithaca, N. Y.

Wilhelm Miller.

### Nægeliæ.

NOW that the frost has killed everything I had out-of-doors except a few Kniphofias, I must look for solace to such things as are under glass. This is not a season for abundance of greenhouse flowers for one who grows no Chrysanthemums, yet I have a few plants which I now enjoy.

Last spring I sent an order to Holland for one hundred *Nægeli*s in five kinds, but the nurseryman through some mistake sent me fifty kinds, and I have had great pleasure in watching their growth and blooming. The first one began to blossom in August and has sent up spike after spike, and is now, after two months, at the end of October, covered with flowers. These plants are ornamental in foliage as well as in flower. The leaves are nearly heart-shaped, toothed on the edges and of an almost fleshy substance, but their beauty consists in their plush-like service. Some are bright green, some have a green ground with broad black, brown or red veins; some have broad patches of crimson on a yellow ground, some are olive with edges of green and crimson, with black veins; but it is impossible to describe the variously colored leaves so as to give a clear idea of them, as no two varieties are exactly alike. These colors are mostly due to a covering of short hairs distributed over nearly all of the upper surface.

The flowers are as varied as the foliage. Nearly all have throats of white or yellow or both thickly or sparsely dotted with brown, crimson or pink. In some cases there is a broad margin of rose or pink or crimson; in some cases the color of the throat, yellow or white, shades insensibly into these other colors; sometimes the flowers are of a pure, unspotted yellow, bluish or white. They are also of elegant shape and are thrown well above the foliage in pyramidal spikes.

The *Nægeli*s are not inclined to dry off of themselves, and I usually cut them off at the ground at the end of November, however fresh they may seem at the time; for, while the rhizomes may, perhaps, not need rest, they are not hurt by being compelled to take it, nor could they well be divided if kept growing; moreover, if the pots containing them can be put away under the bench for three months we gain room for other things at a time when space is scanty under glass. The cultivation of *Nægeli*s is very simple; the rhizomes are much like those of *Achimenes*; that is, they consist of fleshy scales set along on all sides of a central fibre. They are more loosely strung than those of *Achimenes*, being intermediate between these and *Tydas*s; they are also very much larger, attaining sometimes the size of a man's thumb. They should be planted in March in rich and reasonably light soil in five-inch pots. One in a pot is enough, and I prefer to lay them on their sides with the tip, the growing point, in the centre. Of course, very little moisture is needed until they begin to grow.

### Honor Bright Tomato.

THIS seems to me one of the most distinct varieties of Tomato yet introduced. The vine, though strong-growing and vigorous, with large leaves, is a peculiar yellowish green color, quite noticeable even in the cotyledons. It is very productive, bearing its fruit in large clusters. It comes into blossom and develops full-sized fruit as early as any of the forty sorts with which I have compared it, but it was the latest of all to ripen its fruit. All tomatoes turn a lighter green as they begin to ripen, but the fruits of this variety become so light as to justify one in calling them white. They then gradually turn yellow, which color, though in a lighter shade, covers the fruit as completely as it does on the fruit of *Golden Queen*, though at this stage there are darker spots about the stems. A faint blush then appears, which deepens and spreads until the whole fruit, when fully ripe, is a rich but rather light red. This ripening process and change of color takes place very slowly, much more so than in any other variety, as I have already suggested. Early in the season I thought this sort would compete with the *Atlantic Prize* in earliness, yet it was the last of all varieties to furnish ripe fruit, and perfected only the smallest portion of its crop before frost. The fruit is a little above medium size, nearly round, with no distinct sutures, and very uniform and symmetrical in shape. The flesh is very solid even when fully ripe, quite dry, and there is comparatively little pulp about the fairly abundant seeds. The skin, though thin, is very hard and firm. The flavor is fair, and would be specially pleasing to some because it is so mild, but it lacks, even in fruit ripened on the vine, the sprightly vinous flavor which is to me the great charm of tomatoes. That which distinguishes this sort from all others is its slow-ripening habit. This quality, united with its solidity, may make this variety one of the greatest value. It is said that fruit can be picked when yellow, packed in barrels and sent long distances, as to Europe, and will be in ripened and good condition on arrival at its destination. I can readily believe this possible, for I placed some yellow fruit in the cellar and some on the shelves of a greenhouse, and

found them of beautiful color and fair quality twenty-one to twenty-eight days afterward. I wish the quality of the fruit was more to my personal taste, but in *Honor Bright* we certainly have an entirely new type of tomato, and one which, if it does not itself prove to be of practical value, is certain to lead to the introduction of sorts that will.

### Contrasts in an Old Garden.

To the Editor of GARDEN AND FOREST:

Sir,—A garden developed through the care of a hundred summers and prized for the tender associations of a long lifetime, comes to wear a marked individuality of its own, and it is not strange if it enforces with somewhat commanding power its special object lesson in the art of gardening. In one of these old gardens lately seen the value of effective contrast was strikingly displayed. Age has almost closed the ears of the owner to outer dissonances. Her bees and her flowers live together in harmony and peace, and among them her hours run on happily while she delights in showing her favorites and telling their little histories. "I always put my *Salvias* here between the white flowers," she commented, when I exclaimed at the sight of a great blaze of scarlet between huge segregated clumps of *Day Lilies* and a thick row of the tall white perennial *Phlox*. There were trees behind, sun and shade mingled, and the simple, dazzling contrast of the pure color with the lilies, and the great soft heads of white *phlox*, both set off by abundant green, was charming. The garden proper lay beyond, enclosed within wire netting. It is the garden of a farmer's wife, and "father," a white-haired, silent man, stiff with labor, loves "mother's" flowers almost as well as she does herself, and is sure that she has a genius for growing them. The season through it is plain that an eye for color has guided the whole arrangement of the place. It was shown in spring when the great *Dogwood* flowered, and its high, alluring masses of picturesque bloom were set against the dark old *Cedar-tree* behind it; when the *Trumpet Creeper* above and the *Tiger Lilies* below flared and mellowed along the gray wall of the "back sheds"; when the *Wistaria* and the *Baltimore Belle* were both rioting in their glory. At all times a refined contrast served to emphasize in a surprising degree this plain old homestead, with its large, rambling buildings, its variety and amplitude of leafy shade and coolness, and the compact and crowded flower-garden which has overflowed to form borders and colonies in every available corner of the big "dooryard." There is nothing formal, nothing ambitious, yet here is a place where many a professional gardener might take lessons in combining with true skill the elements of his art.

The importance of contrast in a garden compares with what the artists call "values" in a picture. The wonderful variations of color and form caused by light and shade are not generally recognized by the untrained eye, yet as the art student is bidden again and again to discern this quality he finds by a gradual dawn of perception that this is indeed a kind of mystery where the invisible becomes visible through concentrated attention. In painting, all good coloring to be harmonious and beautiful must first be true, and rest upon this basis of a faithful adjustment to the comparative force of light. The common light of day, prosaic as we find it through custom, and, indeed, unnoticed, is still an ever-present marvel of infinitude and perfection. "Of course, snow is almost never white," a landscape-painter once said to me, "it is usually yellow in the sun and blue in the shade, sometimes quite a deep purple." This will sound like nonsense to many, yet observation shows that it is true.

If juxtaposition does not actually change colors, as the magic of strong sunlight seems able to do, it has a vast effect upon the whole impression. It is not enough to avoid the contrast of colors that "kill" one another. A constant gain by means of reciprocal effect is the thing to be sought, and it will bear long study. With my friend in beautifying her old garden, it has been, apparently, instinctive. An unconscious impulse surely gathered together all the soft rosy shades of the *Sweet-Pea* hedge, for which the wire netting is utilized, and the big bed of *Sweet Williams* close by, with wave-like fringes and billows of white *Petunias* extending to the more pronounced tints of the summer *Carnations*. On the other side the background is of *Zinnias*; then, solidly massed, *Coreopsis* and many *Marigolds* in gold and lemon colors. *Nasturtiums* in all their warmth of lavish reds and yellows make a great tent-like screen around a rustic seat. A fine bed of perennial *Lark-*

spurs is near enough to give all the force of contrast to its unrivaled blue. Cornflowers and a hundred other pretty annuals are scattered wherever there is room, with many a cushion of fragrant Mignonette or Sweet Alyssum interspersed; and the bunches of cut flowers that these borders supply are always as fragrant as they are profuse.

One secret of the perfection of this rare old garden is the fearless use of the wheelbarrow. With all the gentleness that seems to belong inevitably to the lover of flowers, its owner is gifted with the strong trait of decision. Annuals, perennials, cuttings multiply everywhere, and there are always, one would say, too many plants, though all seem to thrive, but nothing is allowed to keep a position where it carries itself insolently as an intruder. If a weed is a plant out of place, how many weeds there are assiduously cultivated in some very showy gardens. Homely as are her ways, perhaps, "mother" has really a genius for her own task. She certainly knows how to make a garden that is a complete and beautiful whole, and not a mere collection of more or less interesting plants.

Amherst, Mass.

### Experiences in Fertilizing Potted Plants with Wagner's Solution.

To the Editor of GARDEN AND FOREST:

Sir,—In 1894 I made notes regarding the use of this form of plant-food upon rooted cuttings of several species of common house-plants. The solution has been tested quite extensively by Professor Paul Wagner, Director of the Agricultural Experiment Station at Darmstadt, and the results of his trials are embodied in an illustrated pamphlet of sixty-seven pages, entitled, *Die Anwendung Künstlicher Düngemittel im Obst- und Gemüsebau, in der Blumen- und Gartenkultur*, the third edition of which was published by Paul Parey, Berlin, 1893. The solution contains phosphate of ammonia, thirty grams; nitrate of soda, twenty-five grams; nitrate of potash, twenty-five grams; sulphate of ammonia, twenty grams. Add water to make 100 liters, or about twenty-six and a half gallons.

We used in our experiments Pelargonium (Geranium), var. Luster, six plants; Begonia compta, six plants; Heliotrope, twelve plants. Several other plants, including Carnations and Cinerarias, were treated with the solution.

At first the plant-food in solution was given to the rooted cuttings which had just been potted; but the plants began to drop their leaves and show signs of unthriftiness, and the solution was withheld for three weeks. They had then recovered, and were making a good growth. Lot No. 1 comprised two plants each of Begonia and Pelargonium and four of Heliotrope; these were potted in rich soil made by composting good turf with about one-third its bulk of stable manure. These plants received no additional plant-food. Lot No. 2 consisted of the same number of plants as lot No. 1. These were potted in the same kind of soil and watered with the solution, and lot No. 3 contained the same number of the same varieties of plants as lots Nos. 1 and 2. These plants were potted in a soil of anthracite coal ashes, to which five per cent (by weight) of moss-peat had been admixed. These plants were watered with the solution.

Beginning September 18th, the solution was administered whenever the plants needed watering, with the exception of the plants in lot No. 1, which received water instead of the solution. The plants in lot No. 2 soon began to grow, and were the largest of all. One plant in lot No. 3 decayed at the stem and roots, and was removed. The plants were repotted December 1st. Those in lot No. 1 had good roots, while those in lot No. 2, which had much larger tops, had a root-system much smaller, and those of lot No. 3 had almost no roots. This was true of the several species as well as of the individual plants grown under this treatment. The Carnations seemed to be injured instead of benefited by so much plant-food, the largest plants being those grown in the soil alone. Heliotrope plants grew as well in the coal ashes as in the soil when both received the solution. The smallest plants were those of lot No. 1, which received no liquid fertilizer. Pelargoniums and Begonias grew best in the compost with the solution, but the plants in lot No. 3, for the most part, were smaller than those of No. 1.

About the first of January, 1895, some of the highly-fed Pelargoniums began to wilt, and the wilting continued even when the soil was saturated with moisture; the point had been reached, evidently, where the small root system was unable to supply moisture as fast as it was given off by the leaves. As soon as it was apparent that the plants could not recover under

the same treatment they were removed from the pots and the soil was carefully washed from the roots. The plants were then severely cut back, potted in ordinary soil, and they recovered.

The results of these tests point to the conclusion that while the amount of moisture in the soil influences the development of the root system as explained by Sachs,\* the amount of easily available nutritive matter in the soil also exerts a considerable influence upon the size of the root system. The overfeeding of plants is said to cause a decay of the root-hairs which are quickly replaced by new ones; probably this is what happened in the case cited above. The symptoms, however, were not those stated by Sorauer, who says:† "The case becomes more serious if the concentration of the water contained in the pot becomes too strong, owing to a too rapidly repeated application of manures. The growth of the upper portions of the plant is then visibly retarded, the internodes are shortened, and the leaves become puckered, owing to a shortening of the midrib and lateral veins, or are bent in various directions, spotted, and fall off at an early period. The roots themselves are short, thick and bent up, and the newly formed root-hairs are irregular and shortened, soon become brown and discolored and die away."

In this experiment the plants had every appearance of thrift until they were found in a wilted condition. A superabundance of easily soluble and, therefore, easily available plant-food enables the plant to take up the required amount without sending out long roots to search for it. Large conducting roots are unnecessary, the root-hairs near the stem being able to take up all the plant-food that can be assimilated by the plant.

Since making the cultures described above we have constantly used the same solution, but applied it less frequently, with excellent results. One application a week for the slower-growing and woody plants, and two applications for the more rapid-growing herbaceous plants, seem to be all that is needed. This method of feeding potted plants is much neater than the use of liquid manure; it often renders repotting unnecessary, and is cheaper than the proprietary forms of prepared liquid plant-food usually found upon the market.

Agl. Exp. Station, New Haven, Conn.

W. E. Britton.

### The Forest.

Are the Trees Receding from the Nebraska Plains?‡

IT is a question of no little interest, both botanically and economically, whether the forest trees upon the Nebraska plains are receding from a former wider distribution.§ I do not here refer to such changes in distribution as are made by man, who in some places is removing the forest trees, and in others planting and growing them. These changes, which are directly due to man's interference, are of greater interest in other portions of the country, but upon the plains another question appears, involving the slow changes due to natural causes, and having nothing whatever to do with men's activities.

There are, all told, sixty-five species of trees which grow naturally within the limit of the state, yet for a great part of its area but a small per cent of these are to be found in any particular locality. The greatest number occurs in the south-eastern corner of the state, and from this point the species decrease as we pass north-westerly. To particularize, as we enter the state at its south-eastern corner we find that there are ten species of Oaks, but after traveling one hundred kilometres (sixty to sixty-five miles) westward or north-westward we find that there are but two species, and within a few kilometres (five to ten miles) one of these disappears, unless we follow the bluffs of the Missouri northward. The trees of the Walnut family present a similar interesting distribution. The Black Walnut has extended its range along the south line of the state, in the Republican valley, for 350 kilometres (200 to 220 miles), and northward along the Missouri and Niobrara rivers for fully 700 kilometres (435 miles). The Butternut, on the contrary, does not extend more than 100 to 125 kilometres

\* *Physiology of Plants*, p. 256.

† *A Treatise on the Physiology of Plants*, p. 73.

‡ A paper read before the botanical section of the American Association for the Advancement of Science, in Detroit, August 10th, 1897.

§ GARDEN AND FOREST, vol. vi., p. 46. Vol. vii., p. 509.

(sixty to seventy-five miles) from its point of entrance. The Shellbark, the Big Hickory-nut and the Pig-nut have little, if any, greater range than the Butternut. So if we take up almost any of the species they are found to have entered the state from the south-east and to have passed northward and westward to greater or less distances. There are, however, a few species (nine in all) which seem to have entered from the west. One is the Buffalo Berry, *Shepherdia argentea*, which is scarcely entitled to be called a tree, since it rarely attains to either the form or dimensions of one; it has, however, succeeded in traveling further than any other of the western arboreal species, reaching the Missouri River on the east and the Republican on the south. The next in extent of distribution is the Yellow or Bull Pine, which enters the state at two points and stretches eastward for long distances. Near the north-western corner of the state, Pine Ridge, with an elevation of 1,500 metres (4,600 feet), extends eastward from the Wyoming Mountains, and after about 150 kilometres (ninety miles) passing over the line into South Dakota. On this elevated ridge, which is quite mountainous in many places, the Yellow or Bull Pine is found in abundance, and it has passed from the ridge to the abrupt and rocky bluffs of the Niobrara River, down which it has extended to within less than 100 kilometres (sixty miles) of the river's mouth. About 125 kilometres (seventy-five miles) south of Pine Ridge is a similar but higher uplift of land, Cheyenne Ridge, which extends eastward between the North Platte and the Lodge Pole rivers for a distance of nearly 200 kilometres (125 miles). Its highest points, known locally as the Wild Cat Mountains, attain an elevation of about 1,700 metres (5,300 feet), and from these the ridge descends gradually to 1,200 metres (3,700 feet) at its eastern extremity. Upon this extended ridge this Pine has extended for at least 150 kilometres (ninety miles). It is found also in widely isolated cañons in the central part of the state, near the eastern border of the great Sand-hill belt.

The other trees which have invaded the state from the west have followed one or the other of these two ridges. Thus, the Quaking Aspen (*Populus tremuloides*), Black Cottonwood (*Populus angustifolia*), Mountain Maple (*Acer glabrum*) and Cañon Birch (*Betula occidentalis*) follow Pine Ridge for from fifteen to 125 kilometres (ten to seventy-five miles). On Cheyenne Ridge Rydberg's Cottonwood (*Populus acuminata*) has pushed in from the Wyoming foot-hills for a distance of from fifteen to twenty-five kilometres (ten to fifteen miles). It is interesting to mention here that the very pretty smaller Mountain Mahogany (*Cercocarpus parvifolius*), which further south-west becomes a small tree, enters the state on Cheyenne Ridge, where it grows luxuriantly as a rather tall-spreading shrub on the precipitous slopes of the Wild Cat Mountains.

Looking over the whole area, and studying attentively the condition of the trees along the borders of the areas which they occupy, we may ask whether they are advancing or retreating. At one time I held the view that the eastern trees were advancing and the western retreating, but further examination has somewhat modified this view. Along the western border of the area occupied by the Bur Oak (*Quercus macrocarpa*) the trees are found upon the sides of the narrow valleys through which flow the creeks and rivers. These trees are young and vigorous, and have every appearance of having obtained recently a foothold. Further down these streams the trees are larger, and finally we come to groves of mature trees. The same facts may be observed with less emphasis with regard to the Red Oak (*Quercus rubra*), Black Walnut, Bitter-nut Hickory (*Hicoria minima*), Kentucky Coffee-tree (*Gymnocladus dioica*), Honey Locust (*Gleditsia triacanthos*), Green Ash (*Fraxinus lanceolata*). All of these species appear to be moving westward, the trees of the most westerly stations being nearly always young and vigorous.

With the western species it is nearly the same. While at some stations the Pine-trees upon outlying borders are apparently the remnants of a former larger growth, in

many other places these outliers are growing and vigorous. This was particularly noticeable in a recent visit to Cheyenne Ridge, where but one explanation could be given for the present distribution of individual trees upon the spurs and hillsides. It is very certain that upon Cheyenne Ridge the Pines are slowly pushing eastward, and that, in spite of the ravages of man and of herds of cattle, horses and sheep, this species is more than holding its own. Upon some parts of Pine Ridge man's interference has checked the advance of the Pine, and this is the case also in some places along the Niobrara River, but in many other places the young trees are springing up and vigorously contesting with Grasses and weeds for the possession of the ground. The Mountain Maple and the Cañon Birch give one the same impression of a successful and comparatively recent advance into a territory formerly unoccupied. Even the shrubby Mountain Mahogany upon the slopes of the Wild Cat Mountains is evidently fighting a winning, and not a losing, battle. No one can ride through the mountain cañons and see the vigorous plants of this pretty species and come to any other conclusion than that there is here a strong eastern advance of a western species.

With respect to some of the trees upon the Nebraska plains I have to admit that it is at present impossible to see either advance or retreat. It is probable that in some instances, as for example the Paper Birch (*Betula papyrifera*), the trees have remained where they are for ages, without perceptible change in area. Perhaps we have in this tree a survival from the glacial migration from the far north. Likewise, I find it impossible to pronounce upon the status of the Basswood, Cottonwood, Elm, Silver Maple, Buckeye, Cherries, etc. They have as yet not shown anything which is conclusive either way.

From such evidence as we have thus far, it is evident that some of the eastern trees are advancing toward the west, and that some of the western trees are advancing eastward. In other words, we can say that some of the species are not receding from the Nebraska plains, and that as to other species the evidence of advance or retreat is wanting.

Lincoln, Nebraska.

Charles E. Bessey.

## Exhibitions.

### Chrysanthemums in Philadelphia.

THE annual Chrysanthemum exhibition of the Pennsylvania Horticultural Society, held in Philadelphia last week, was generally considered one of the best in recent years, especially in the classes of cut chrysanthemums, orchids and decorative plants. The Chrysanthemum-plants shown by the Penn Rock Company and by Gordon Smirl were excellent, and won several prizes. Among other winners of awards for plants were John McCleary, J. E. Kray, Henry B. Surman, G. Wilbur Brown, John McGowan, James O'Brien, Mathew Bracken, William Robertson and John Mitchell.

In the classes of cut chrysanthemums Percival Roberts, Jr., Esq. (John Cullen, gardener), won a special premium of a silver cup for a magnificent collection, not in competition. A delicate pink seedling shown by Henry B. Surman, gardener to E. W. Clark, Esq., was awarded first premium, and a new yellow sport from Mrs. Jerome Jones was awarded a certificate of merit; the latter was shown by George F. Baer, Esq., Reading (Ferdinand Heck, gardener). The new Pennsylvania, noted in the account of the exhibition in Boston last week, attracted much attention, and was awarded a silver medal and also a certificate of merit. The color is a clear yellow and the flowers appear to the best advantage under artificial light. Hugh Graham & Son were the exhibitors of this promising novelty. First prizes for cut flowers were also awarded to A. Herrington, Madison, New Jersey; Henry Weber & Son, Oakland, Maryland; E. M. Wood & Co., Natick, Massachusetts; John McCleary; John T. Harrison, Bethayres, Pennsylvania; Wm. K. Harris, Robert G. Carey, Edward Jones, Martin Montague, William Robertson, Henry G. Standen, Jos. Monahan, John Mitchell and George Middleton.

The Henry A. Dreer Co. showed an unusually fine collection of decorative plants, including a group of *Cibotium Scheidii* and one of *Latania aurea*, besides a notably interesting exhibit of aquatics. Hugh Graham & Son, Mrs. George B. Wilson and A. Woltemate showed large and

valuable collections of Orchids. Thomas Logan, gardener for Mr. William L. Elkins, Jr., exhibited a new *Dracæna*, *D. Elkinsii*, which was awarded a certificate of merit. A silver medal was won by Henry T. Clinkaberry, gardener for C. G. Roebeling, Esq., Trenton, New Jersey, for the new American seedling *Cypripedium*, Edwin Lonsdale. This is described as a hybrid variety from *Cypripedium Rothschildianum*, fertilized with *C. barbatum superbum*, being the first cross from *C. Rothschildianum* that has ever bloomed. The foliage is intermediate between that of *C. Rothschildianum* and *C. barbatum superbum*, being very fleshy. It is evidently a free grower, being in perfect health. The flower-stem is two inches in length. The slipper resembles that of *C. Rothschildianum* in form, with the color of that of *C. barbatum superbum*; sepals three inches long, profusely blotched with brown spots on light green ground, rosy purple points, hirsute appendages along edges; dorsal sepal somewhat broader than that of *C. Rothschildianum* and of similar markings, suffused with rose.

A large number of seedling Carnations were shown, many having real merit. The premium for the best American seedling was awarded to C. W. Ward, Queens, Long Island, for Mrs. James Dean, a light pink, the edges somewhat fringed. Peter Fisher, of Ellis, Massachusetts, was awarded a certificate of merit for a new Carnation, Mrs. Thomas Lawson; John Burton won the same honor with a new white Carnation, as did William Swayne, for a new crimson variety named Empress. Joseph Heacock won the Craig Cup with a new pink variety, Elizabeth. William P. Craig won a first prize for 100 cut flowers of Flora Hill. Vegetables and fruits of high quality were shown in profusion as in former years.

Horticultural Hall, the beautiful permanent home of the Pennsylvania Horticultural Society, lends itself admirably to floral decoration, and on this occasion the spacious foyer and exhibition halls and the broad staircases were delightful in their luxuriance and in the wealth of color.

### Notes.

The flowering in England of our *Cornus florida* is an unusual occurrence, and the fact is interesting, recorded by a correspondent of *The Garden*, that two trees at Grayswood Hill, Hastemere, flower more or less every year and some years abundantly.

A portrait of the base of the trunk of a remarkable specimen of the so-called Red Cedar of the north-west coast (*Thuja plicata* or *gigantea*) is published in a recent issue of *The Pacific Rural Press*. This tree stands near Snoqualmie Falls, on the Seattle & International Railway, and the circumference of the trunk at the ground is given as one hundred feet and seven inches. As this is one of the slowest-growing of the western conifers, this tree has probably lived for more than a thousand years.

In the display of timbers representing 118 varieties made at the Nashville Exposition by the Nashville, Chattanooga & St. Louis Railroad, and occupying ten thousand square feet of floor space and a large outside area, are two remarkable specimens of Yellow Poplar (*Liriodendron Tulipifera*). One of these is a log forty-two feet long, ten feet four inches in diameter at the butt, and seven feet in diameter at the smaller end. This specimen contains 1,260 cubic feet and is about 600 years old. The other specimen is forty-eight feet long with an average diameter of seven feet.

The pale yellow-flowered Japanese *Prunus Maximowiczii*, which was first figured a few years ago in this journal (vol. vi., fig. 31), has been raised in the Arnold Arboretum from seeds brought by Professor Sargent from northern Japan, and, although it has not flowered yet in this country, it gives every hope of success here in its rapid healthy growth and perfect hardiness. At the end of October the plants were conspicuous from the scarlet coloring of the leaves, which are even more brilliant than those of *Prunus Pseudo-cerasus*, its associate in the forests of Yezo. Of the deciduous-leaved trees entirely new to cultivation this Cherry is certainly one of the most promising and interesting.

The opening of the new Agricultural Building of the Tuskegee Normal and Industrial Institute, at Tuskegee, Alabama, is announced for November 30th. Some 1,500 young negro men and women are receiving a liberal and practical education in this widely-known school, of which Mr. Booker T. Washington is the President. Professor G. W. Carver, Chief of the Agricultural Department of Tuskegee Institute, writes us that a few years ago the present horticultural grounds were

little more than shifting sands and gullied hillsides, with here and there small tufts of *Yucca*, *Cactus* and similar plants. The President from the start recognized the possibilities of this important feature of his school, and the first invoice of material consisted of a miscellaneous lot of trees, ornamental shrubs and other plants, which were disposed of not according to their fitness for the place, but according to the fitness of the place for them, and the vegetable garden, orchard and flower garden all blended more or less into each other. As time passed and the soil improved the division lines became more and more apparent, until there is now an orchard consisting, approximately, of 1,380 Peach-trees, 50 Plum-trees, 1,300 Grapevines, 20 Fig-trees, 20 Quince-trees and 120 Pear-trees. The San José scale made its appearance a few years ago, and is being vigorously fought. This pest, in connection with drought and other local troubles, has affected the results, but, aside from these drawbacks, the horticultural work has been successful. Pears have equaled those from California in size and in abundance. Plums have been grown with pronounced success, the Burbank and several types of the Japanese having done especially well. Figs and Grapes flourish here, and 18,000 Strawberry-plants are under cultivation. The gardens, lawns and campus have been transformed, flowering plants, native and introduced shrubs being freely used. Bermuda Grass is depended upon for the lawns. Hon. James Wilson, Secretary of Agriculture, will deliver the principal address on the occasion of the opening of the Agricultural Building, which has been erected at a cost of \$10,000, and other guests will include the donors of the building, the Governor of Alabama and the State Superintendent of Agriculture. The first floor contains the industrial class-rooms, with a seating capacity for seventy-five persons. The large museum-room contains sections devoted to botany, geology, histology, entomology and ornithology. In the chemical laboratory students will receive instruction in practical analysis in the animal, vegetable and mineral kingdoms. The upper floor is devoted to the dairy lecture-room, agricultural lecture-room, herbarium and reading-room, and the basement to dairying, cheese-making and similar uses.

An interesting collection of tropical fruits reached this city recently from the Botanic Gardens in Grenada, a British possession, the southernmost island in the Windward group. The consignment was shipped on October 23d. A delay of ten days in entering the fruits at this port, due to the unusual character of the invoice and the want of established rates of duty, proved fatal to many of the more perishable kinds, but enough survived to give distinct character to the select stock in one of the fancy-fruit stores on Broadway. These West Indian fruits included especially juicy oranges of excellent quality. The Tangerines and Mandarins were superior, and sold, as did the oranges, at \$1.00 a dozen. Among other citrus fruits were lemons; these were less attractive, being of uneven size, thick-skinned and rough. The limes were remarkably good, and sold for forty cents a dozen. An unusual offering in this city were citrons, the fruits of *Citrus Medica*, familiar to housekeepers in their candied peel; there were undersized green fruits and mature ripe specimens; the latter, cut with a piece of the stem, were lemon-shaped, large as grape-fruits, the rough skin unevenly colored in shades of lemon and orange. These sold for twenty cents each. In this unique collection sapodillas, the fruits of *Sapota achras*, were fortunate in showing to better advantage for the long time consumed in reaching customers, since these are at their best when more than fully ripened, and the grayish earth-colored globular fruits were in the juicy sugary stage. They sold for fifteen cents each. A single specimen of the brownish-yellow fruit of *Lucuma mammosa* was exhibited, and some of the large brown nuts. Alligator pears were among the fruits lost through the delay, and the few bananas which were yet edible were remarkably good in quality, the yellow fruit of medium size having rich, creamy white flesh, while the red bananas were of especially fine flavor. The latter, one of the most rare of all fruits in this market since the supply was cut off by the Cuban war, found eager purchasers at \$1.00 a dozen. Several bundles of stick cinnamon also sold readily. Among choice offerings now regularly in trade are Gros Colman grapes, from England, and from Newport, the former costing \$1.75 a pound, and the latter twenty-five cents less. Hothouse-grown cucumbers and tomatoes are as bright and attractive as the most showy of fruits. The so-called Spanish melons, from Italy; richly colored pomegranates, from California, as brilliant as the showiest of apples; Japanese persimmons, from Florida; and English cob nuts, in their husks, are other reasonable offerings in the best stores.

# GARDEN AND FOREST.

PUBLISHED WEEKLY BY

THE GARDEN AND FOREST PUBLISHING CO.

OFFICE: TRIBUNE BUILDING, NEW YORK.

Conducted by . . . . . Professor C. S. SARGENT.

ENTERED AS SECOND-CLASS MATTER AT THE POST-OFFICE AT NEW YORK, N. Y.

NEW YORK, WEDNESDAY, NOVEMBER 24, 1897.

### The Soldiers' and Sailors' Monument.

EVERY one who is concerned to-day in the erection of a monument of any sort in this city wishes it placed in Central Park, where, as a rule, monuments do not belong and could not be properly placed to secure their best effect, and where they would injure the effect of the park itself. When a site within the Park cannot be secured, a position close to one of its chief approaches is desired. This is a more justifiable wish. But, again, its result cannot be good unless the character of the proposed monument and the manner of its placing both conduce to dignity and harmony of general effect. No greater mistake can be made in such a matter than the placing of a monument, however good, in such a way that it will embarrass the designer who may hereafter be called upon to treat the remainder of the space in which it stands, or to supply those monumental entrances which were contemplated by Messrs. Olmsted & Vaux when they designed the park itself.

Just now this matter is peculiarly important, when \$250,000 have been secured for the erection of a Soldiers' and Sailors' monument in this city. Neither the wishes of those army and navy men who desired to have the monument placed on Riverside Drive, where the tomb of their great leader stands, and where it would be visible from the water as well as from the land, nor the recommendations of the experts asked by the committee of city officials to advise in regard to its site, were regarded by this committee. Moved by the too general wish to connect their monument with Central Park, and to place it where it would be seen, not by the greatest number of persons, but by those who roll by in their carriages, a site close to the Fifth Avenue and Fifty-ninth Street entrance has been chosen. The designer of the monument has also been chosen. Competent judges declare that the schemes which he presented were good in themselves, and would be less offensive on the selected site than any offered by other competitors. Nevertheless, if this monument is set on the indicated spot it will seriously hamper the work of any artist who may hereafter be commissioned to treat the Plaza and the adjoining park entrance in a systematic and proper way.

Mayor Strong, who has done much for the beautifying of New York during his three years' administration, tried to do one thing more when he declared that nothing whatever ought to be placed on or near the Plaza until two million dollars had been appropriated for its right adornment as a whole. This even now would be a difficult task. Tall and ugly buildings occupy two sides of the Plaza, and the lines of the streets and park roads which run out from it cannot be brought into harmony with an absolutely symmetrical scheme. But a symmetrical scheme is not the only possible good one even in urban adornment; and if two sides of the Plaza are badly built upon, the Park to the north and the great Vanderbilt house to the south with the vista of Fifth Avenue beyond it, supply conspicuous elements of beauty. A really able designer can still give us a beautiful Plaza if no more incongruous elements are introduced before he gets to work, and if he is not too closely hampered by that love of exact symmetry which in many of our architects has recently developed into an unreasoning passion, not unnaturally in view of the discord and heterogeneity which most parts of our city display. A perfectly balanced and majestically uniform effect can never be produced on this spot; but a dignified, harmonious and effective one may be achieved if every foot of it is now jealously preserved intact until such time as its embellishment as a whole may be undertaken. Until this time comes, however, the most careful artist cannot erect any monument within sight of the Plaza and keep its general effect in mind; for, of course, he cannot divine how this effect may eventually be conceived. The only safe way is to do nothing here, but for the time being to place all contemplated monuments in localities for which so comprehensive a plan is not required. There are many such situations not far from Central Park, and it ought still to be possible to secure the placing of the Soldiers' and Sailors' Monument in one of them, and to consider again the advice given by the experts who were consulted by the committee in the first instance. Or, if this is impossible, the site should at least be shifted a little farther north. The monument should not stand in the large circle at Sixtieth Street, which is an integral part of the Plaza, but at the extreme northern end of the Plaza between Fifth Avenue and the entrance to the driveway of the park. Here such a form as the selected architect has chosen would be quite as appropriate as on the proposed site; and it might be worked with less difficulty into that general scheme for the adornment of the Plaza and the park entrances which, at some future day, the city will certainly wish to take in hand.

VENERATION for very large or old or otherwise remarkable trees is an indication of civilization and cultivation which is not always as common in America as it should be. In every country of Europe exceptionally large and old trees are revered, and it would be considered a sacrilege to injure them. Their portraits are frequently published and their histories are familiar to all classes of the community. As the primeval forest disappears its remnants become sacred, and if we in this country are not more alive to the necessity of preserving our remarkable trees it is, perhaps, because we have not yet lost the instincts for forest destruction inherited from ancestors who, forced to cut trees in order to raise bread, had their hardest struggle with the forest. Too often we hear of noble trees being needlessly sacrificed even in the oldest and most civilized states, and it is, therefore, pleasant to know that a determined effort will be made by some of the inhabitants of Media, Pennsylvania, to preserve from destruction a remarkable group of four Sassafras-trees standing in the neighborhood of that town. The largest of these trees at three feet from the ground is twelve feet six inches in circumference and about eighty feet in height; the others are nearly of the same size and all are healthy and symmetrical. These are the largest Sassafras-trees east of the Mississippi River of which there is any record,

and even in southern Arkansas, where this tree grows to its greatest perfection, it would be difficult to find many individuals to equal them. The owner of the trees having declared his intention of cutting them down this winter, the attempt will be made to buy the land on which the trees stand or the right for them to grow indefinitely. It would be more than a local and state misfortune if this movement failed of success or if these trees, which are probably several hundred years old and are still in perfect health, should not be allowed to live to show the size and beauty our Sassafras, the only species in all the world, can attain under favorable conditions.

#### Notes on Cultivated Conifers.—VIII.

IN *Pinus* the world finds some of its most valuable timber-trees and a few park and garden trees of great beauty and interest. The genus is well distinguished by its clustered secondary leaves which are enclosed in the bud by numerous scales which lengthen with the growing leaves and surround their base with a thin, more or less persistent, sheath. *Pinus* is further distinguished by its involucre, fascicled, staminate flowers and by its woody cones, which mature at the end of their second, or rarely at the end of their third season. *Pinus* is widely spread over the northern hemisphere, forming on maritime plains, mountain slopes and dry interior plateaus vast continuous forests, or is scattered singly and in groups through deciduous-leaved trees. About seventy species are now recognized by botanists who still have much to learn of the Pine-trees of Mexico, Central America and the interior of China. In the United States thirty-four species, or about half of those now known to science, find their homes; the genus is largely represented in Mexico, northern India, and in all the region bordering on the Mediterranean, which in number of species is the stronghold of the genus in the Old World. Various methods for grouping the species in sections have been proposed. That based on the number of leaves in each cluster, which, less scientific than the one now generally in use, is perhaps the most satisfactory for cultivators who often have to deal with plants which are not large enough to produce flowers or cones. Adopting this method of arrangement the species of *Pinus* fall, with some exceptions, into three sections—the first with five leaves in a cluster, the second with three leaves in a cluster, and the third with two leaves in a cluster. On the trees of the first section the leaves are usually long, slender and blue-green with deciduous sheaths; the cone-scales are usually thin and mostly unarmed, and the wood is soft, light-colored and homogeneous; on those of the other sections the leaves are, as a rule, much stouter and usually dark yellow-green; their leaf sheaths are mostly persistent during one or many seasons, their cone-scales are thickened and generally furnished with spines, hooks or prickles, and their wood is hard, heavy and marked with broad bands of resinous cells.

For our region the most valuable ornamental trees are found in the first section. These are all inhabitants of northern or of elevated countries and most of them flourish in the north-eastern states. The type of this section, *Pinus Strobus*, our native White Pine, is the most valuable tree of the whole genus for the parks and gardens of the wide region which it inhabits naturally. Wherever a collection of trees was planted in the north-eastern states more than fifty years ago the White Pine is found to surpass all other conifers, when any others have survived, in height, thickness of trunk and health. Impervious to the cold of the Canadian winter and the burning suns and dry winds of the prairies of Kansas, the White Pine flourishes also as no other exotic conifer flourishes in central Europe; and in the gardens of northern Italy it is as vigorous and beautiful as it is in the forests of Michigan and Minnesota. The brittleness of the branches of this tree, which frequently break under a load of snow or frozen sleet, is the one drawback to the White Pine as an ornamental tree, the symmetry of

isolated specimens being frequently ruined from this cause. The White Pine grows well on dry sandy drift gravels, but only attains its noblest dimensions on well-drained rich soils, when its roots can reach abundant and constant moisture. In cultivation here at the north it will usually outgrow from the start almost every other conifer, but newly planted seedlings do best when they are protected from wind and sun, for the White Pine is a shade-enduring species, and in the forest the seeds germinate most freely and the seedlings grow for many years most vigorously under the shade of other plants. No other tree breaks up so well the flatness of the forest roof, and no other tree that can be used here is so valuable to enliven the monotony of a sky-line with its dark green wide-spreading crowns raised high on stately stems. Only a few abnormal forms of the White Pine are cultivated. *Pinus Strobus nivea*, which is probably of nursery origin, is distinguished from the ordinary form by its rather lighter-colored bark, shorter paler leaves and denser foliage. More distinct than this is *Pinus Strobus nana*, a low compact, round-topped bush, seldom growing more than five or six feet tall, with abbreviated crowded branches and short leaves; this is, perhaps, one of the most distinct and beautiful of all the dwarf conifers in cultivation. A dwarf form with pendulous, nearly prostrate, branches is grown in the Arnold Arboretum, where Mr. Dawson has also propagated plants from a remarkable tree growing in the town of Dracut, Massachusetts, with short, slender, nearly erect branches usually in whorls of three, forming a dense low round-topped head.

In the section *Strobus*, to which our White Pine belongs, are two west American Pines, *Pinus Lambertiana* and *Pinus monticola*. The former, the Sugar Pine of California, is the largest of all Pine-trees, individuals over 200 feet in height with trunks ten feet in diameter being not uncommon. Although this tree was introduced into English gardens as long ago as 1831 by its discoverer, David Douglas, it has never proved very successful as a cultivated tree. Removed from its native forests, where its growth is rapid and vigorous, it increases slowly both in Europe and the eastern United States, where it is perfectly hardy as far north, at least, as Massachusetts. Differing from *Pinus Strobus* while young only in its stouter and darker leaves, it has in our climate no advantage as an ornamental tree over our own White Pine, which grows much more rapidly, and the Sugar Pine will probably never be much cultivated here except as a curiosity.

The second western American Pine of this section, *Pinus monticola*, is also a great tree, only surpassed in magnitude by the Sugar Pine. This is a widely-scattered species, being distributed from the western slopes of the northern Rocky Mountains, over a large part of the elevated regions of the west, growing from the level of the sea on the shores of the Strait of Juan de Fuca to about 10,000 feet on the California Sierras, where trees with enormous stems and short contorted branches withstand for centuries the fiercest mountain gales. *Pinus monticola* has proved perfectly hardy in the neighborhood of Boston, where it has already produced cones. The cultivated trees can be distinguished from *Pinus Strobus* by their narrow pyramidal habit, short remote branches and rather thin foliage, and in beauty do not compare with the native species. Like the Sugar Pine, *Pinus monticola* will probably never be largely used by eastern planters.

In Asia the section *Strobus* has a representative in *Pinus Nepalensis* (the more usually accepted name of this tree, *Pinus excelsa*, is unavailable, as it has been used before for another species), an inhabitant of Himalayan forests, where it is scattered from Afghanistan to Bootan between elevations of 5,000 and 12,000 feet above the sea-level. This is a beautiful tree with long, slender, tufted, drooping foliage, attaining sometimes in its native forests a height of 150 feet. For many years this Himalayan Pine has been used in temperate Europe and in the eastern United States for the adornment of parks and gardens. Growing while young with great rapidity in cultivation, it often suffers in

the eastern states from the splitting of the bark, and in New England, where it is otherwise hardy, it is usually short-lived. Further south *Pinus Nepalensis* is more successful, and there are now large healthy cone-bearing trees in the Central Park, New York, and in the neighborhood of many of the cities of the middle states.

In Europe *Strobus* appears in *Pinus Peuce* of the mountains of Macedonia, Servia and Montenegro, a tree which has been sometimes considered a geographical form of the Himalayan White Pine, from which it differs, however, in its much shorter and more persistent leaves. In the Arnold Arboretum, where *Pinus Peuce* is quite hardy, it differs from the Indian tree in its closer and more pyramidal habit and denser foliage. This is a slow-growing tree here, with no special ornamental value, and is chiefly interesting as the European representative of a group principally indigenous in the New World.

The Pines which we have mentioned all belong to a subsection of *Strobus* in which the wings of the seeds are longer than the seeds themselves, but there are other five-leaved Pines, with pale, soft, straight-grained wood, which have seeds with narrow wings much shorter than the seeds. To this group belong the Rocky Mountain White Pine (*Pinus flexilis*). See f. 19 in the current volume of GARDEN AND FOREST, a beautiful tree widely distributed over the mountain ranges of the interior of the continent. It is hardy in the neighborhood of Boston, but in the east grows very slowly, suffering severely here from fungal diseases, and plants thirty-five years old are not more than four or five feet high, with tufts of miserable stunted foliage on the ends of naked branches. In England *Pinus flexilis* appears to do better than it does on the Atlantic seaboard, and in the Royal Gardens at Kew there is a tree twenty-five feet in height and probably of the same age as the Boston specimens, which were raised in the Harvard Botanic Garden from seeds collected by Dr. Parry in 1862 in Colorado. A year ago the Kew tree produced cones.

Another Pine of this sort, *Pinus albicaulis*, also inhabits the mountains of western America; it is an alpine tree, distinguished by its thin creamy white bark and short, nearly oval, cones with much thickened scales. This tree is said to have been introduced into Scotland in 1851 by John Jeffrey, who discovered it in that year on the mountains which rise above the valley of the lower Fraser River. I have never seen it, however, in Europe, and it has not been tried in this part of the country. Like other trees which grow naturally only at high altitudes, it will probably grow very slowly at the sea-level, even if it could be induced to grow here at all.

*Pinus Cembra*, the Swiss Stone Pine, is another of the White Pines with narrow seed-wings. It is a native of the mountains of central Europe, of northern Russia, and of Siberia where it sometimes forms pure forests of considerable extent. *Pinus Cembra* is always a slow-growing tree, with short, slender horizontal branches which in youth form a dense compact pyramid, and stout rigid blue-green leaves clustered at the ends of the stout branchlets. This tree is an old inhabitant of gardens and is perfectly hardy in New England, where, however, it grows very slowly, retaining its dense, handsome pyramidal form until it is twenty-five or thirty years old, and then frequently becoming thin and ragged. A species, *Pinus pumila*, nearly related to the Stone Pine covers the high summits of the mountains of northern Japan with broad, almost impenetrable, thickets four or five feet high, and is widely scattered also over Saghalin, Kamtschatka and the Kurile Islands. This shrub has probably never been tried in our gardens, where it may be expected to be hardy and to grow very slowly.

In Japan the five-leaved Pines are also represented by *Pinus parviflora* and *Pinus pentaphylla*. The former is one of the most attractive of the exotic Pines which decorate our gardens. It is a common inhabitant of mountain forests above elevations of five thousand feet, through which it is found scattered either singly or in small groves, occa-

sionally growing to a height of sixty or seventy feet. This tree is a great favorite with the Japanese, and one of the principal subjects which they employ in dwarfing. In our gardens, where there are now specimens from twenty to twenty-five feet in height, *Pinus parviflora* grows rapidly, sending out long picturesque, persistent branches clothed with tufts of blue-green leaves and loaded with short oval cones which, after ripening, turn nearly black and do not fall for months. This beautiful tree, which is still rarely seen in this country, is admirably suited for the adornment of small gardens. The other Japanese five-leaved Pine (*Pinus pentaphylla*), recently distinguished by Mayr, is a rare inhabitant of the mountain forests of southern Yezo. This little-known tree, long confounded with *Pinus parviflora*, has been raised in the Arnold Arboretum, where it seems to be hardy enough, although it is still too early to say much about it.

*Pinus Koraiensis* is a small five-leaved Pine, which is another really valuable plant in the gardens of the north-eastern states. A native of Corea, northern China, Manchuria and Kamtschatka, it was long ago introduced into Japan, probably by Buddhist priests, and is now one of the plants commonly seen in temple gardens. From Japan it was brought to the United States about thirty years ago and has proved entirely satisfactory here. In the color of the leaves it resembles *Pinus Strobus*, but it is more compact in habit and the foliage is much more dense, as the leaves do not fall until their fourth or fifth year, and therefore clothe the branches for a long distance back from the tips, while in *Pinus Strobus* the leaves mostly fall during their second year, leaving the branches bare, except at the extremities. *Pinus Koraiensis* now grows freely in the neighborhood of Boston, producing seeds, which, like those of all the five-leaved Pines with narrow seed-wings, are large and edible.

C. S. S.

#### Notes from South-western China.

The following notes are from a personal letter from Dr. Augustine Henry, dated at Mengtse, September 9th of this year:

I may mention that I have found a magnificent *Paulownia* with evergreen leaves, which is the most gorgeous sight when in flower imaginable. *Lonicera Hildebrandiana*, discovered by General Collett in the Shan States, also occurs here in the mountains. It is a rambling shrub, climbing over rocks. The flowers are deep yellow and about seven inches in length. *Leucosceptum canum*, of northern India, is a remarkable Labiate, common in mountain woods at about 5,000 feet altitude. It is a tree some twenty feet high, and in habit is exactly like a *Buddleia*.

Yunan is a large province, and is associated in the minds of botanists with the wonderful discoveries of Père Delavay. He collected mainly in the west of the province on the high mountains near Tali, which are practically spurs of the Himalayas. The region here, that is, Mengtse and to the south, crossing the Red River, and extending as far as the Shan States under French control, is very different from Delavay's ground, and will probably turn out as rich in species, new and interesting, but not so suitable for introduction into cultivation, as the mountains do not rise to the heights seen in the vicinity of Tali. Here, nevertheless, are many fine *Rhododendrons*, and there is a great variety of *Cyrtandreae*. These are always beautiful plants, occurring as a rule in shaded parts of mountain forests, mainly on rocks. A good many *Begonias* also occur in the same habitat.

The forests are more beautiful as one approaches and enters French territory, simply because the Chinese have not been there long enough to destroy them. They are migrating southward all the time and opening up forest land to cultivation. Curiously enough, it is two American plants which enable them to extend cultivation high up on the mountains, namely, Maize and the common Potato (*Solanum*); and the opium Poppy, too, can be cultivated with profit to a high altitude. In ancient times the aborigines, who were the only inhabitants of the mountains, depended almost entirely on the Tartar Buckwheat (*Fagopyrum Tartaricum*), which succeeds much better at high elevations than the common Buckwheat (*F. esculentum*). South of the Red River there was scarcely

a single Chinese sixty years ago, but now there are many settlements and the forests are disappearing.

There does not seem to be one Frenchman in the northern part of Indo-China interested in botany, and this is a great pity, as the mountainous part of their territory is finely forested and rich in plants, and French officers, civil and military, are scattered everywhere in isolated posts. The botanical source of some of their interesting products is quite uncertain. For example, the Cassia-bark which is cultivated in the Chinese province of Kwangsi and reaches foreign countries by way of Pakhoi and Canton, is undoubtedly the product of *Cinnamomum Cassia*, but from Annam there is a very large export of so-called cinnamon, which is a different thing, and the tree yielding it is unknown. Another curious export happens to be known, as specimens were found in China. This is what the French call "faux gambier." It is the root of a wild Yam (*Dioscorea rhipogonoides*), and is much used by the Chinese in dyeing.

I forgot to mention in regard to cinnamon that the Chinese give fabulous prices for certain varieties which occur in the mountains of Tongking—as much as \$50.00 for two pieces of bark fifteen inches long and four inches wide, to give a concrete example. Such bark is supposed to cure all diseases. It would be very interesting if some French official on the spot would collect botanical specimens of the trees, the bark of which has such a commercial value.

Travelers and residents in foreign countries are always possessed with the idea that anything with a common general name is thoroughly known to science; and we are still in the dark in consequence in regard to the sources of certain kinds of rhubarb, cinnamon, indigo, textile fibres, etc.

As an example of the interest in cultivated and useful plants I may cite the Sweet Potato. This is cultivated largely in China, and is unquestionably an introduction from America. But the plant cultivated in central China and in Yunnan is *Ipomoea fastigiata*, and not the common form of *I. Batatas*. Mr. Hemsley is of opinion that the latter is only a cultivated variety of the former species, which is known in the wild state.

## New or Little-known Plants.

### *Prunus Pseudo-cerasus*.

THIS is a native of eastern Asia, where it is widely spread from Japan to central China, Saghalin and Manchuria, and is a noble tree in the forests of Yezo. There is still much confusion with regard to the Asiatic Cherries of this group, and whether the wild single-flowered tree which is figured on page 463 of this issue from specimens gathered in the forests near Sapporo is really the plant described by Lindley as *Prunus Pseudo-cerasus* or not we are unable to determine, as some of the numerous double and single flowered varieties cultivated by the Japanese are possibly derived from still little-known allied Chinese species. Under whatever name, however, it should be known by, this Cherry of northern Japan promises, as has lately been stated in these columns, to become a valuable ornamental tree in the north Atlantic states.

It is a glabrous tree, growing in the forests of Japan seventy or eighty feet in height, with a trunk frequently three feet in diameter, covered while young, like the branches, with lustrous light red-brown bark, oblong elliptical or obovate coarsely serrate leaves abruptly contracted at the apex into long points, corymbose white flowers from a quarter to a half of an inch in diameter, opening with the unfolding leaves, and small pea-shaped fruits with thin flesh.

Very conspicuous in early spring when covered with its abundant flowers, *Prunus Pseudo-cerasus* is also conspicuous and very beautiful in the autumn when the leaves turn dark red. The wood of this tree is highly esteemed in Japan, where it is largely used principally for carving and for blocks used in printing cloth and wall paper.

In the Arnold Arboretum young trees of this Cherry are in perfect health and are growing rapidly, and, although they have not flowered yet, they show in autumn the splendid leaf color which is one of the great attractions of the Japanese forest at this season of the year, just before the Maples, which change color a little later, light them up with more brilliant shades of scarlet.

## Foreign Correspondence.

### London Letter.

**NERINES.**—The genus *Nerine* has been a favorite greenhouse plant for flowering in late autumn from the earliest times, and one species, *N. sarniensis*, which is grown in large quantities by the Dutch and other bulb growers, is distributed when dry in the same manner as Hyacinths, Tulips, etc. There are fifteen species, according to Mr. Baker, and some of these have been crossed with each other by Dean Herbert, Max Leichtlin, Moore, O'Brien, Mansell and others, so that we now have a large number of seedlings and crosses of more or less horticultural value. Mr. Elwes has recently been at work upon the genus with a view of obtaining late-flowering varieties, for instance, such as might be had in December. There is no reason why, in the course of time, this should not be accomplished. Meanwhile, he has got together a large collection of sorts in his garden at Colesbourne, and the group he exhibited at the last meeting of the Royal Horticultural Society showed that he is a master in the art of growing and flowering these plants. In addition to the older standard sorts he exhibited a number of new seedlings, eight of which received certificates. They are all named in compliment to some lady, such as Lady Lawrence, Lady Bromley, etc. Mr. Elwes has evidently worked principally with the various forms of *N. sarniensis*, which include those known in gardens as *Plantii*, *venusta*, *corusca* and *rosea*. These, with *N. curvifolia* and its variety, *Fothergillii*, are the best of the genus in point of color, vigor, etc. This habit of growing in winter and resting in summer makes the cultivation of *Nerines* somewhat difficult in localities where sunlight, so essential to good growth, is obscured by fogs and general murkiness, as, for instance, at Kew; but where these are not experienced they may be grown as easily as Daffodils. They require liberal treatment while growing, say from October to April, to be followed by absolute rest induced by drought and exposure to air and bright sunshine until the flower-spikes show in September.

**PROTEA CYNAROIDES, var. ELLIPTICA.**—This is a dwarf shrub compared with the type, of which an illustration, prepared from a plant grown at Kew, was given in GARDEN AND FOREST (vol. viii., p. 34). A plant of the former is now flowering freely in the Cape house at this establishment; it is a yard high, freely branched, and each branch is terminated by a flower or bud, or rather flower-head, measuring eight inches in diameter and composed of a cup-like whorl of stiff, pointed, lanceolate, petaloid bracts colored flesh-pink, the whole of the centre being occupied by a cushion-like mass of stamens, which are united, except round the margin. For a cool house, such as suits Cape Heaths, this is a commendable shrub, as it flowers freely when small, while the flowers are not only exceptionally attractive in size, form and color, but they have the merit of lasting six or eight weeks or even longer. The Kew plant was raised from seeds sown in 1890, and it first flowered two years ago. I can recommend the genus *Protea* as worthy the attention of horticulturists in such states as California.

**LONICERA HILDEBRANDIANA.**—It is nearly four years since this plant was introduced to Kew from Burma, but we have not succeeded in flowering it yet, although it grows most vigorously in the varying conditions under which it is being tested. It was discovered in Upper Burma by General Sir Henry Collett nine years ago, who described it as "a conspicuous shrub with large, dark glossy leaves and fine crimson flowers seven inches long." At Kew it is a stout climber with stems twenty feet long and ovate leaves six inches by four inches. It is not hardy, but grows freely in the Winter Garden. Meanwhile, Mr. Hildebrand wrote from Burma in April last, "I am sorry that you are unable to flower the large Honeysuckle. It is a sight to behold just now in my garden and surprises the densest observer in horticultural matters. It is a mass of

flowers, white when they first open and of a lovely gold when far spent. It flowers on last year's wood." There is evidently some mistake with regard to the color of the

Kew, where it first fruited three years ago. It has long, quick-growing, angular climbing stems, which attain a length of twenty or thirty feet before flowering, and they

Fig. 58.—*Prunus Pseudo-cerasus*.—See page 462.

flowers. I hope to hear of its flowering shortly in California.

**MOMORDICA MIXTA.**—There are three fine fruits of this splendid tropical gourd on a plant in one of the stoves at

bear numerous large palmately lobed, smooth, shining dark green leaves and one-flowered axillary peduncles. The male and female flowers are borne on separate plants, the male flowers being about three inches

across with velvety cream-white petals blotched with purple at the base. The male plant is worth a place in a warm conservatory as a handsome-flowered climber. The female flowers, which are smaller, when artificially fertilized develop large egg-shaped or oblong fruits nine inches long, the surface clothed with closely set spine-like points an eighth of an inch long; when ripe these fruits are of a rich scarlet color, on which account I should class them among the most ornamental of the Gourd family. The species is a native of India, China, etc. Good seeds were matured in quantity by this plant at Kew last year.

**THE MANGOSTEEN** (*Garcinia Mangostana*).—Fruits of the Mangosteen have lately been received at Kew from the Botanic Gardens, Trinidad, where trees have been established and have borne fruit since 1875. The tree is a native of the Malay Archipelago, and is cultivated in various parts of India. It forms a small conical tree twenty or thirty feet high, with bright green, Laurel-like, leathery leaves and fruits the size of an orange, with a hard smooth rind, colored dull purple, enclosing a spongy mass of pulp, which is divided into eight sections, as in the orange, two or three only of the sections containing each a single seed about the size of a plum-stone. The pulp is the delectable part, being white or pink, very juicy and of an agreeable flavor, suggesting that of the Granadilla. In the east the Mangosteen is considered to be the choicest of all tropical fruits; I question, however, if it would win such a position in temperate climes when pitted against the apple, pear, grape and pineapple. Still it has the charm of novelty, and would probably find a market here. The fruit appears to keep and carry as well as an orange.

**THE DURIAN** (*Durio-zibethinus*).—This is another Malayan fruit-tree which is celebrated for its large delicious fruits; delicious, that is, to those who have overcome its powerful disagreeable odor. Fruits of it have lately been produced by a tree in the island of Dominica, in the West Indies, and one of them was sent to Kew, where I ventured to taste it, half-rancid and evil-smelling though it was. I never want to taste it again. It is a large evergreen tree with the habit of a Pear (according to an example in the Palm-house at Kew, which is fifteen feet high), and oblong, long-pointed, gray-green leaves clothed with scales beneath. The fruit is like an enormous sweet chestnut, as large as a child's head, covered with hard spines and enclosing a mass of cheese-like pulp, in which the four or five large seeds are embedded, the pulp being the edible portion. The tree is said to be commonly cultivated throughout the Malayan peninsula and islands, where its fruit, during the period it is in season, forms the greater part of the food of the natives. The flavor of the Durian is unique, no other fruit combining such a delicious flavor with such an abominably offensive odor, which has been compared to that of rotten onions. When once the repugnance to this odor has been overcome the fruit becomes a favorite, Europeans becoming extremely fond of it. Mr. Wallace, in his *Malay Archipelago*, says: A rich custard highly flavored with almonds gives the best general idea of it, but there are occasional wafts of flavor that call to mind cream cheese, onion sauce, sherry wine and other incongruous dishes. . . . The more you eat of it the less you feel inclined to stop. In fact, to eat durians is a new sensation worth a voyage to the east to experience! From the condition of the fruit sent from the West Indies to Kew I should say the durian is a bad traveler. Still it ought not to be hard to overcome this difficulty, at any rate for the journey from the West Indies to the United States, where a fruit with such a character as Mr. Wallace describes ought to find a ready market.

**NEW HYBRID ORCHIDS**.—Messrs. J. Veitch & Sons exhibited two new hybrids last week which were awarded certificates. They were *Cattleya Olivia*, a hybrid between *C. Trianae* and *C. intermedia*, showing the influence of both parents in the habit and form of its flowers, which were of a rich peach-blossom color suffused with yellow; *C. Melpomene*, a hybrid between *C. Mendelii* and *C. Forbesii*,

with rose-colored flowers, the lip shaded with yellow and brown, with a heavy marginal fringe. A hybrid between *Cypripedium Haynaldianum* and *C. Chamberlainianum* was shown by Mr. E. Ashworth, and obtained a certificate. It is the first hybrid raised from the last-named species, but there was a doubt expressed with regard to the other parent. The hybrid has a white dorsal sepal lined and spotted with rose and brown, the petals are spirally twisted and colored green and brown, while the lip is rose-colored, tinged with green and yellow. A pretty variety of *Lælia Lucasiana* was shown under the name of *L. longipes*, and obtained a botanical certificate.

### Japanese Plums.

IT is hardly ten years since Japanese plums began to attract the attention of fruit growers in the United States to any considerable extent, but it is now certain that they have won a permanent place among the cultivated fruits of this country. The best of them rank only good to very good in flavor and quality when compared with such varieties as Bavay's Green Gage, Washington, Jefferson and other choice kinds of the European species, *Prunus domestica*. The Japanese Plums are not exempt from black-knot, and, wherever I have had opportunity to observe them, are fully as susceptible to injury from leaf-spot (*Cylindrosporium padi*) as are the ordinary kinds of Plums. Our Plum orchards suffered from an unusually severe attack of aphid the past season, and native Plums of the Chickasaw, Americana and intermediate groups, together with the Japanese sorts, were injured worse than the varieties of *Prunus domestica*. Japanese Plums are apt to have the fault of the Wild Goose and many other native kinds in that the ripening fruit drops from the pedicel quite readily. Some of them, like Kelsey, are so tender that they cannot be fruited in the north. Ogon is the hardiest in fruit-bud of the kinds fruited here, but it is not as hardy as the Italian Prune and others of the hardiest *Domestica* kinds.

The colors of Japanese plums range from the clear yellow of the Ogon to the beautiful clear red of Red June and the darker, duller red-purple of Satsuma. Sometimes Burbank has a brilliant red cheek deepened to almost red-purple with yellow background, but neither the blue nor purple shades of the prunes and damsons characterize any Japanese plums. In some varieties the yellow is shaded with green, resembling somewhat the color of a Green Gage plum, and nearly all varieties have a delicate bloom, which, when it softens such brilliant hues as those of Red June and Wickson, adds much to the beauty of the fruit.

As compared with *Domestica* plums, none of the Japanese kinds rank best in quality, yet some of them have a sprightly, agreeable flavor and attractive colors, and are good enough in quality to sell well. Some kinds, like Abundance and Burbank, begin bearing very young, and are so exceedingly productive that it is advisable to practice thinning, not only to increase the size of the remaining fruit, but also to prevent injury from overbearing. Willard and Ogon ripen before the earliest of the *Domestica* kinds, and October Purple, one of Mr. Burbank's latest productions, as its name indicates, carries the season for Japanese plums late into the fall.

It is not at all probable that Japanese plums will supplant the older cultivated kinds where the latter can be grown to perfection as readily as can be done in central and western New York and in various other sections of the country, but they will doubtless supplement them to some extent. In some portions of the Hudson Valley, where the ravages of black-knot practically prohibit commercial orchards of *Domestica* Plums, the Japanese varieties are being grown successfully, and while not altogether exempt from black-knot, so far as my observation goes, they are practically free from that disease even where *Domestica* varieties near by are severely attacked.

As they are succeeding in some locations where black-knot is prevalent, and because of their wide range in season of ripening, their vigor and productiveness, their attractive colors and good shipping qualities, Japanese plums, as already remarked, have won a permanent place among our cultivated fruits. On this account it is especially unfortunate that in the process of introducing them into cultivation here much confusion in their nomenclature has arisen. Thanks to the efforts of some of our pomologists, and especially of Professor Bailey, whose Plum bulletins should be in the hands of every grower of this fruit, some progress has been made toward

establishing a correct nomenclature. The fact that seedlings of Japanese plums are apt to resemble the parent fruit very closely has made it all the more difficult to detect synonyms, and it is impossible always to identify a variety with certainty from illustrated descriptions.

In the interest of a uniform nomenclature it is desirable to call attention to the very interesting report of Mr. Orpet on Japanese plums in the current volume of *GARDEN AND FOREST* (page 347), and point out some of the instances in which the varieties as grown by him are evidently not true to name.

First, it may be said that the Japanese Plums are classed as *Prunus triflora*, not *P. Simonii*. Mr. Orpet voices the general opinion when he calls the Burbank the best of the Japanese plums, but its fruit is not "as large as a moderate-sized peach." Wickson is the only hardy Japanese plum yet introduced which answers that description. Kelsey is so tender that Professor Bailey, in his bulletin 131, says of it: "We still hear of Kelsey being fruited in New York, but in every case which we have investigated some other Japanese variety has been misnamed the Kelsey. The farthest north which I have known the true Kelsey to fruit is southern Delaware."

Mr. Orpet describes the Kelsey as greenish yellow and smaller in fruit than Burbank, but the true Burbank varies from an inch and a quarter to an inch and five-eighths in diameter, while the true Kelsey varies from two to three inches in diameter, and in color is of a bright red purple over yellow background. He speaks of Satsuma and Wickson as having a spreading habit of growth. Satsuma is somewhat open in its habit, but Wickson is decidedly upright, resembling *Prunus Simonii* in this respect, as also in its rather narrow conduplicate leaves. Possibly Mr. Orpet has the names Wickson and Burbank interchanged, for Wickson bears very large, attractive fruit of good quality, while Burbank has smaller fruit and is decidedly spreading in its habit.

Abundance is not quite equal to Burbank in quality, neither is it more attractive in appearance or more productive, but because it is a little earlier some have found it more profitable, especially during the past season, when by the time Burbank was ripe the markets were so loaded with other plums that prices ruled lower than they did when Abundance was ripening.

### Recent Importations among Chrysanthemums.

**F**ORTY-SEVEN varieties are but a small proportion of the whole number of new kinds of Chrysanthemums annually imported into this country, but among this number grown at the Cornell Experiment Station this year and last, are many that will be welcomed in America as distinct advances. The twelve Californian varieties (which are here included as foreign sorts), the four Australian and thirty-one European varieties (mostly English, from H. Cannell & Sons, Swanley, Kent) were tried in the same bed with eighty-eight American novelties of 1896 and 1897, and thirty-one seedlings sent to the station in advance of their introduction to the trade. These, with some thirty-four old and successful types, made a total of two hundred varieties with which the foreign sorts were obliged to compete on equal terms. The most remarkable feature of the collection was the scarcity of white varieties and their general failure. White is the most important single "color" in the trade, and there are said to be more new white sorts introduced every year than any other color.

Of one hundred and sixty-six novelties here reviewed nearly thirty per cent were pure white. Mrs. F. Hepper was distinctly inferior to our American favorite, Mrs. Henry Robinson, Alps to Mrs. J. Peabody, Taiwan to Mrs. R. Craig, White Swan to L'Enfant des deux Mondes, and Pride of Swanley, though not fully mature yet, can surely not rival Yanoma. Lady Esther Smith, which was recorded in Cornell Experiment Station Bulletin 136 as a new type of the greatest promise, has been a total failure this year in spite of the unprecedented success of the trial as a whole. Among the yellow varieties a welcome addition is a large, rather flattish, flower, named W. S. Devis, with rays an inch or more wide, as in Lady Esther Smith. It has only seven or eight series of rays, and a large disc, which, however, would not be objectionable even if it were not well hidden. It is as bold a yellow as Constance Terrell. Governor Budd is a yellow Chrysanthemum of the size and form of Philadelphia, and fades as badly, but begins with an orange of the shade of Pitcher & Manda. Triumph de St. Laurent is almost, if not quite, equal to H. L. Sunderbruch, one of the standard, midseason, commercial sorts. A. H. Wood is a quilled sort with a prominent disc, useless for the trade, but by reason of its marked individuality a worthy subject for

skilled amateurs, and one of the finer creations which private gardeners are on the lookout for. It will not stand shipment. Duchess of York is one of the best additions of recent years to the amateur list. We have not learned its special requirements yet. This variety and Defender were the only two sorts which suffered a loss of foliage at the base. The foreign bronze and buff varieties were numerous, but contained only three notable kinds. Mongolian Prince is the perfection of the Chinese type, and its roundness should make it excellent for shipping. It is a dull but rather rich color and too formal and regular to be a great favorite in America. Helen Owen is a fine whorled sort, but not suitable for the cut-flower trade. Buff Globe is a sport from the well-known pink Good Gracious, but is fuller and has a stronger neck. Khama is a good Japanese red, with characteristic and beautiful foliage. The color fades no more than any other red of the shade of Pluto or Loantika.

The Amaranth varieties, apparently, are more esteemed abroad than with us. Among the large reflexed sorts, Wood's Pet is by far the best of this color that we have seen in four years' testing of novelties. The form is precisely that of Vivian-Morel. Of the Japanese Incurved type it would be hard to choose between Australia, General Roberts and Pride of Madford. In all three the silvery reverse is the chief feature, the amaranth interior being suggested rather than disclosed. The first hides its disc, and the last two show it at an early stage, giving a striking effect upon which opinions are sharply divided. (There are two varieties circulating in England under the name of Pride of Madford, one of which is worthless.)

Among the pink varieties I see no advances. Most of the hairy sorts are of the familiar Japanese Incurved type, of which Mrs. Alpheus Hardy and Louis Boehmer are familiar examples. A new departure among the hairy sorts is the pink variety, Mrs. P. Rothenbush, which is reflexed, and soon shows its yellow disc. It can hardly be recommended. I see no improvement in the dark colors. For the exhibitor and private grower of skill Oriental Glory and Bellem are two sorts worthy of trial. The flowers are very large, last a long time on the plant and have marked individuality of form and color. Bellem has never been pink with us, as in England. It is the best primrose-yellow we know despite the great height of the plant and the awkwardly curled foliage.

The curiosity list has received two interesting additions in Mrs. J. Carter, a ball of shredded, tangled white, and Mrs. Filkins, which is smaller than Mrs. W. H. Rand, but just as much cut up and equally charming. Centaurea and Souvenir de Madame G. Eynard are two others which Cannell has introduced as "boutonniere, æsthetic and spidery" Chrysanthemums. The two last-named are not equal to our variety Shavings for attractiveness. The best of this list is Alice Carter, which, though curious, is agreed by all to be beautiful, and seems to be entirely new in form and color. The foliage is proportionately small and delicately cut. These novelties, while obviously different from other Chrysanthemums, should, according to the practice of the National Chrysanthemum Society of England, be classified as Japanese. This word, which was once used to designate geographical origin, has now come to be synonymous with miscellaneous or unclassified.

#### Uncultivated Crops in the Ozark Mountains.

To the Editor of *GARDEN AND FOREST*:

Sir,—Among the most interesting wild crops produced in the stony Ozark country, owing to its economic value, is Japan Clover, *Lespedeza striata*. The time and manner of the introduction of this pretty annual trifoliate into the United States do not seem to be definitely known. The Department of Agriculture mentions it as having been first noticed near Charleston, South Carolina, about 1849, and says that the seeds probably came from Japan in boxes of tea; also that it was found a little later some forty miles from Charleston, and soon after at Macon, Georgia, and that it has now become naturalized as far west as Texas and north to the Ohio River. It has taken possession of the rocky Ozark hills, and furnishes an ample supply of nutritious forage in a region that was, previous to its arrival, devoid of green food for stock. It is eagerly eaten by the cattle and hogs that range through the woods, and they are not only kept in good condition by it during summer, but with the addition of the mast that is abundant, they come off the range in the fall fat enough for market. Milch cows also live on it.

Japan Clover is less attractive on dry or poor soil and where it is eaten over by stock than when grown under better conditions. In a fairly favorable location it makes luxuriant growth and becomes really ornamental. Indeed, its beauty and its ability to adapt itself to various conditions of light, shade, drought and moisture in this limestone district are leading to its trial as a lawn covering, particularly in shaded grounds where grass is especially unsatisfactory. It is certainly invaluable in the Ozarks.

Pennyroyal neatly clothes with a subdued color acres of high, dry and stony land where no other herbaceous plants try to live. The plants extend for miles along the roadways, and all of this refreshing aromatic herbage is wasted.

Indian Currant (*Symphoricarpos vulgaris*, locally known as Buckberry) forms another noticeable and abundant crop, occupying situations similar to those in central Illinois which are overgrown by Hazel bushes, and in about the same proportion. It is, in fact, the leading shrub, largely predominating in the undergrowth of southern and south-western Missouri, where but few Hazel bushes are seen. Sumach is not plentiful, and Elder is almost unknown. The wild growth of the Indian Currant furnishes many suggestions for its use in cultivated grounds in the same region. It forms fine, irregular belts and large straggling plantations at the verge of open glades and along the border of woodlands; and in sunny situations, even on hilltops and steep hillsides it is seen in clumps and single well grown plants, springing from stony soil and set among boulders and on projecting ledges of rocks. These plants frequently attain good proportions, and the gracefully drooping branches sweep the ground on all sides. Everywhere among the hills this desirable shrub is seen loaded with its small dark red berries.

Brighton, Ill.

*Fanny Copley Seavey.*

### The Beautifying of a Neglected Field.

To the Editor of GARDEN AND FOREST:

Sir,—I am indebted to GARDEN AND FOREST for the beautifying of at least one of my fields. This was a barren, worn-out hillside of gravel with deep, worn gullies when I bought the place. Following your advice, I allowed it to grow up as it would; I knew that Pines and Junipers would soon cover it. They come up everywhere of themselves, and are now spread over nearly the whole field; they are from ten to fifteen feet high. But it surprised me, in looking over the field this fall, to find Maples, Sassafras, Gum, Tulip and Sycamore trees, and one Holly, besides two kinds of Ferns, three patches of Arbutus and some Crowfoot. The Daisies, Golden-rod, Sumach and Grasses were not to be wondered at. Simply left alone, this is now quite a pleasing field to me. The farmers about think it sadly neglected, but I thank you for advising such neglect.

St. Denis, Md.

*Cynthia Force.*

### Flowering Plants in a Mild Autumn.

To the Editor of GARDEN AND FOREST:

Sir,—The season has been kind to us here, notwithstanding excessively dry weather in the early fall. My notes record the flowering of Crocuses on the 30th of March, and in sheltered parts of the city there have been no killing frosts yet. Nasturtium leaves are bright and are still growing, and there are occasional flowers. Now and then a small Polyantha Rose shows on the bushes, and the last Dahlias are gathered along with the yellow Chrysanthemums.

This is remarkable for the 11th of November, and is an especial encouragement to those who desire to cultivate late-blooming flowers. The tardy but ambitious Cosmos was never so perfect as now and almost justifies its more general cultivation. Where frosts are to be expected in September there is not much satisfaction to be had from it. Fuchsias are bright, but stopped flowering early in the month, and Geraniums have become mere foliage plants. The influence of Lake Erie is so potent in certain localities on its shore that unless there are contending influences of elevation or closed depressions that hold the cold air there is not much fear of frost before November, and yet the season of most plants is past some time earlier, and flower gardens have a lifeless appearance even before the trees have shed their leaves. This is especially true of the wild garden. There are enough late-blooming plants in common cultivation to maintain a cheerful appearance throughout the season, and where frosts hold off very late, as they do in some favored localities, efforts should be made to cultivate a fair proportion of these late-blooming plants.

Not much life is left in the wild garden after the Asters and

Golden-rods are gone, and not a few of these are under the ban on account of their disposition to spread by means of stolons or subterranean roots and choke out everything near them. This is also true of most of the Solomon's Seals, and *Potentilla Anserina* spreads like a Strawberry and neglects to send up its solitary bright yellow flower unless the soil is quite sandy. The Trilliums, Bloodroot and many other early bloomers are as unobtrusive as they are beautiful, while it is an unattained art so far to persuade the *Dicentras*, *Hepatica* and *Claytonia*, as well as some wild members of the Mint family, to continue in the garden long, as they demand soil that is mostly leaf-mold. The most satisfactory wild plant to me is *Thalictrum dioicum*, especially the male plant, which is a Maiden-hair Fern with all the improvements of perfect hardiness, bushy growth and the added wealth of pendent yellowish stamens that dance in the breeze. Another charming plant is *Uvularia grandiflora*, which is in every way worthy a place in the most pretentious garden.

Buffalo, N. Y.

*John Chamberlin.*

### A Delicious Tuber.

To the Editor of GARDEN AND FOREST:

Sir,—Having read of the edible character of the roots of *Apios tuberosa* I was curious to find out what they were like. This beautiful wild plant, clambering over the wayside shrubbery in many parts of rural New England, with its luxuriant habit and the exquisite scent of its chocolate-colored flowers, is familiar to all who know the country. But its curious tubers, strung along the underground shoots like beads on a string, are not so commonly known. I had used the plant to cover a bare wall near the house, and the other day I dug up a few of the tubers. They were about the size of small Seckel pears. I noticed that, even when slightly cut, or pricked, they exuded a gum-like juice, white and sweetish, something like India-rubber, in its elastic nature, and not easily dissolved in the mouth. Possibly this gum might prove to have some economic value. I baked the tubers in the oven for about fifteen minutes and found them delicious. When done they were mealy and creamy white in color. Their flavor was strikingly delicate; something between that of a very fine potato and a sweet potato, with a suggestion of the chestnut, also. If farmers and market-gardeners would take pains to cultivate *Apios tuberosa* they would undoubtedly make handsome profits, for the tubers would be in demand both as a novelty and as a welcome addition to our edible vegetables. It is not unlikely that, with cultivation, new varieties would be developed, perhaps approaching the sweet potato in size, and possibly even improving upon the present flavor.

Malden, Mass.

*Sylvester Baxter.*

### The Forest.

#### Forestry in Women's Clubs.—I.

SOME account of the meeting of the New Jersey State Federation of Women's Clubs, held in Trenton in March, 1896, was given in GARDEN AND FOREST (vol. ix., page 132), with reference to the efforts made on that occasion in the interests of forestry. Mrs. John Gifford, of Princeton, made the principal address, and explained the forest conditions of New Jersey, together with the special beauties and uses of the woods of each region, and gave convincing reasons for the adoption of a conservative forest policy. It was suggested that women could aid in the preservation of forests through their influence in schools, libraries and in public discussions; by offering prizes to school children, and by having in every school district in the state exhibits of maps and photographs illustrating the results of wanton forest destruction and of scientific forest management; by joining forestry associations; in clubs and classes, by taking up the systematic study of forestry in its economic aspect; and in the sympathetic love of trees and of natural beauty and order, out of which would grow village-improvement societies, with forestry committees and the like. The prophecy was ventured by the speaker that if the women of New Jersey would take a positive and active interest in the preservation and protection of the forests of that state, within one year a State Forest Commission would be organized, a radical and practical fire policy would be enforced, so as to save the remnants of forests, and courses of instruction would be

founded which would teach the people of the state to value the forests and to use them wisely. A feature of the meeting on that occasion was an exhibition of maps showing forest reservations in the west, and the forest area of New Jersey; views of the Palisades, in which Nature and Nature's defacements were contrasted; photographs showing the desolation wrought by criminally careless methods of lumbering; illustrations of the expensive engineering work in southern France, due to the mountains having been stripped of their forest cover. Photographs of noteworthy trees and attractive landscapes were other features of this convincing exhibit, together with pamphlets on tree-planting, forestry and village improvement, and a specially prepared pamphlet containing a bibliography of books relating to forestry, village improvement and rural life.

As an outcome of the interest manifested at Trenton, at the national meeting of the General Federation of Women's Clubs held in Louisville, Kentucky, in June, 1896, a resolution was adopted "that as federations of women's clubs and as individual clubs, as far as possible, we pledge ourselves to take up the study of forest conditions and resources, and to further the highest interests of our several states in these respects." These resolutions were afterward printed and circulated among 1,500 clubs in the United States.

The growing interest in forestry was signally shown a few weeks ago in the meetings of the Pennsylvania and the New Jersey State Federation of Women's Clubs, the first held in Harrisburg, Pennsylvania, October 27th and 28th, and the latter in Camden, New Jersey, on the 28th and 29th of the same month. On the occasion of the New Jersey meeting in the spring of 1896, GARDEN AND FOREST remarked editorially that the arrangement of the forestry exhibit was so effective that it seemed a pity that it must be transient, and the suggestion was made that every library and school-room should have something of this kind as a general help in the education of public sentiment. A partial fulfilment of this suggestion has now been realized in the formation of a traveling forestry library, arranged by Mrs. Gifford, as chairman of the committee on Forestry and Protection of the Palisades of the New Jersey State Federation of Women's Clubs, who also introduced the forestry resolution at Louisville a year ago. The library, neatly encased in oak, with a traveling dress of white duck, was a conspicuous feature of the Camden meeting. The catalogue states that the library is intended as an introduction to the study of forestry, and it is arranged in seven classes. As illustrating the range covered, Group A comprises books on Trees and Forestry, and contains *The Woods of the United States*, C. S. Sargent; *Elements of Forestry*, F. B. Hough; *Trees of the Northern United States*, Austin C. Appar; *Management and Protection of Forests*, D. Brandis; *Forest Tree Planters' Manual*, J. O. Barrett; specimen sheets of Sargent's *Silva of North America*. Group B consists of Reports of the Division of Forestry for 1890-91-92-93; besides *What is Forestry*, B. E. Fernow; *Wasted Soils and How to Prevent Them*; *Relation of Forests to Farmers*, B. E. Fernow; *Planting in Western Plains*, *Planting in Waste Places*, *Planting on the Farm*, all by C. A. Keffer; *Age of Trees*; *Defects of Wood*, A. D. Hopkins; *Uses of Wood*, Filibert Roth. Other subjects included in this class of the library are Information to Wood Consumers; Government Timber Tests; Suggestions to Lumbermen; Facts and Figures regarding Forest Resources; Forest Fire Legislation; Is Fire Protection Practicable; Report of the Committee appointed by the National Academy of Sciences upon the inauguration of a Forest Reservation Policy; Rules and Regulations governing Forest Reserves; Public Lands and Their Water Supply; Notes Regarding Department Publications; Arbor Day Planting in Eastern States; and Some Common Birds in their Relation to Agriculture. Group C contains publications of the American Forestry Association; Group D, State publications and papers; Group E, Monographs and Short Articles; Group F, Periodicals and Press Clippings, including sets of *Forest Leaves*,

*The Forester*, a series of editorials, notes, etc., and a portfolio of illustrations from GARDEN AND FOREST, with specimens of foreign forestry periodicals from Switzerland, Belgium, France, Germany, Austria, India and Ceylon; also specimens of American Lumber Journals. Group G contains Reports of Park Boards, etc. The library is to be sent to women's clubs in New Jersey in the order of applications, the expense of carriage to be borne by each club, some member of which shall be responsible for its care and return at the end of a month. Several applications were at once made and the journeying promptly begun.

A circular letter constituted part of the report of the Committee on Forestry and Protection of the Palisades, and in this it was recommended that members of the State Federation see that libraries, schools and reading circles are supplied with forestry literature. The endowment of a forestry scholarship, it was suggested, would speedily lead to the establishment of a chair of forestry in colleges, and that with the approaching need for trained forestry officials in the national reservations the time is ripe for public-spirited effort in this direction. Widespread and intelligent pressure upon our rulers was recommended to overcome the selfish ends of greed, lest, as in the case of the recently declared national reservations, the nation lose control of vast resources which should be held for the benefit and welfare of all. It was specially recommended that members should thoroughly familiarize themselves with every aspect of the Palisades question, with a view to their preservation. In connection with forestry interests, Waldo G. Morse, Esq., one of the New York State Commissioners for the Preservation of the Palisades, made an impressive plea for the Palisades, the address being distributed later in pamphlet form. Miss Vermilye, of Englewood, New Jersey, gave a graphic account of the actual damage resulting from blasts in quarrying the Palisades. In the verbal report of the chairman of the Forestry Committee it was stated that interest in forestry is steadily growing. It was explained that forestry is not a sentimental enthusiasm for beautiful trees in themselves, but that it is an economic science. That a forest is a crop, just as corn and wheat are crops, and exists to be utilized for the benefit of man. Forethought and complex considerations enter into the raising and utilizing of a crop of timber, which make forestry a difficult and intricate science, depending upon the varying conditions of different countries. Our vast resources and optimistic habits of thought have too long delayed the understanding of this beneficent art. Forestry must be practical and must take the financial aspect into consideration. Lumbermen most of all ought to be interested in forestry, because their future supplies are at stake. The forest is a crop and something more, and its direct and indirect benefits are as important as its cash returns. In Europe the state regulates the rotation of the timber crop according to fixed laws, and we are trying to persuade our Government to save the remnants of our vast and beautiful forest possessions, and to protect them from fire and offer inducements to woodland owners in the reduction of taxes. Popular enlightenment must be depended on most of all. Women should first intelligently inform themselves, and then devise adequate means of instruction, to the end that public opinion may become educated.

New York.

M. B. C.

## Notes.

The Department of Agriculture in Circular No. 17 of the Division of Forestry has brought together in a convenient form a summary of recent legislation bearing on state forestry commissions and forest reserves, including the laws of New York, Pennsylvania, Wisconsin and Minnesota, and those sections of the Sundry Civil Appropriation Bill passed on June 4th last which relate to the national forests.

Our correspondent, Mr. Carl Purdy, whose knowledge of the bulbous plants of California and their cultural requirements is unrivaled, describes in the October issue of *Erythea* three new California Lilies; *Lilium occidentale*, from boggy places

in barrens and bogs about Humboldt Bay, related to *L. maritima*, which it resembles in habit, bulbs, leaves, and in the dark red of its perianth tips, but from which it is separated by its much larger flowers, with long revolute lobes; *Lilium Bakerii*, with a bulb similar to that of *L. Columbianum*, is distinguished from that species by the form of the perianth and the delightful fragrance of the flowers which perfume the air for a considerable distance, and is a native of sandy woods along Puget Sound in northern Washington and southern British Columbia; and *L. parvum*, var. *luteum*, a showy form with perianth segments revolute from the base and clear brilliant reddish orange throughout, tipped with red and marked with small bright red spots. This variety is from Plumas County, where it was collected by Mrs. Austin.

Two plants of the Heath family from widely separated parts of the world, *Azalea Vaseyi* and *Enkianthus campanulatus*, were conspicuous a few days ago in the brilliant reds of their dying foliage. In the northern states this *Rhododendron*, with its lovely clear pink precocious flowers, is one of the best of our early-flowering shrubs, and at the end of October lightens up the shrubbery with its brilliantly-colored leaves. It was first figured in GARDEN AND FOREST (vol. i., fig. 60); and, although a native of North and South Carolina, where it was discovered only a few years ago, it has proved perfectly hardy in eastern Massachusetts. *Enkianthus campanulatus*, the representative of a small genus of southern and eastern Asia, is one of the most beautiful flowering plants in Japan. In its native forests it is a tree occasionally thirty feet high, with a trunk sometimes a foot in diameter covered with smooth light red bark, and abundant campanulate *Andromeda*-like white flowers borne in elongated, many-flowered, racemose panicles. Raised in the Arnold Arboretum from seeds gathered by Professor Sargent in 1892, it has so far proved hardy in the climate of Massachusetts, although, of course, it is too soon to form any opinion of its real value as a garden plant in this country. During the last week of October the plants in the Arboretum were particularly noticeable from the brilliant color of the leaves.

*The Rural New-Yorker*, in explaining the long-keeping qualities of New York state grapes, says that grapes, apples and other fruits grown in western New York have superior keeping qualities, due to the soil and climatic conditions. Grapes grown on clay-land are firmer and ship better than those grown on gravel. In Ohio an association known as the Clay-growers' Association handle only grapes grown on clay-lands. The three sections in New York where grapes are grown to the greatest perfection all lie near large bodies of water, an influence favorable to keeping qualities. Of the long list of varieties cultivated in this state the best of the long-keeping kinds are Catawba, Diana, Isabella and Vergennes. To insure keeping they must be carefully handled; it is also important that the temperature be gradually reduced from the vines to cold storage, and there must be no sudden changes. The grapes should be left out-of-doors in crates the night after they are picked; early in the morning they should be removed to a cool building or dry cellar; then to a still cooler room adjoining the storage-room, and here the temperature should gradually fall until the desired point is reached. New York grapes intended for exhibition at the World's Fair were placed in cold storage November 1st, 1892, and held there until spring, when they were shipped to Chicago in time for the opening of the Fair, May 1st. The main supply was then placed in the cold-storage building on the exhibition-grounds. This building was destroyed by fire on July 12th and the reserve stock of grapes was lost, otherwise New York grapes would have been on exhibition every day of the Fair. As it was, but fifteen days intervened between the last showing of cold-storage stock and the arrival of new-crop grapes. Catawba grapes are offered at reasonable rates in the markets of this city as late as April.

*The Gardeners' Magazine* in a recent issue states that the development of the great industry which has been founded on the beet has been possible only in consequence of the progressive increase in the yield of sugar by the roots. In order to obtain exact information on the subject application was made by the Kew authorities to Monsieur H. L. de Vilmorin, who has had a large share in bringing the beet to its present condition as a commercial source of sugar. In reply Monsieur de Vilmorin wrote to Mr. W. T. Thiselton that both his father and himself had devoted much time and attention to sugar beets. Both the beet-root and the leaf-beet are derived from *Beta maritima*, L., a native of the shores of the Mediterranean and of the western coasts of Europe. It was known to the ancient Greeks and Romans in both garden forms. In the eighteenth century large varieties of the beet-root were transferred

from the garden to the field and used as food for cattle, first in Germany, and afterward in France and Great Britain. When Achard initiated the manufacture of sugar from beet-root the white field variety was judged the most suitable for sugar-making; it contained from eight to ten per cent of its weight in pure sugar. Selection was then brought to bear on the existing variety, and in fifty years the percentage of sugar was slightly increased, being raised to twelve or thirteen per cent of the gross weight of the root. After 1850 more accurate means of ascertaining the amount of sugar in each individual root were introduced by the elder Vilmorin, and in a dozen years a race was established yielding sixteen and even eighteen per cent of sugar. The fibrous tissues of the root which hold most sugar had been developed and the cellular tissues reduced to the utmost extent; hence the root became small, hard, dry and easily deformed. Since then the object has been to unite a better shape with an equal amount of sugar. Beet-roots containing more than eighteen per cent of sugar cease to vegetate properly and die.

No more beautiful fruit has ever been seen in our fancy-fruit stores than the Spitzenberg apples, from California, now shown in the best collections. The fine crimson streaks are laid on a flush of a lighter shade, with clear lemon-color showing through in places. The aroma of this apple is delightful, and the flavor and texture are both excellent. These are a specialty with W. & C. Smith, the pioneer fruiterers in this city, at 84 Broadway. Other attractive offerings in their uncommonly interesting display are immense *Easter Beurre*, *Comice* and *Beurre d'Anjou* pears, which range from seventy-five cents to \$1.00 a dozen, and spicy winter *Seckels* from fifty to seventy-five cents. *Coe's Late Red* plums are still shown in good condition, and cost seventy-five cents for a six-pound box. Among California grapes are *Cornichon*, *White Muscat*, *Morocco* and *Verdelle* at seventy-five cents for six pounds. *Almeria* or *Malaga* grapes, from Spain, cost forty cents a pound, and there are hot-house *Gros Colman* grapes. *Persimmons* have recently arrived from Florida, after a scarcity of this fruit during the past month; these are of unusually large size and in their best condition; they cost \$1.00 for a box containing one dozen and a half of the fruits. *Grapefruits*, from Florida, cost \$2.00, and oranges from the same state sixty to seventy-five cents a dozen. *Abakka* pineapples command sixty to seventy-five cents each. While the supply of fresh fruits is no less showy in variety and color than earlier in the season, the buyer has, besides, a wide choice of fruits preserved in various ways. Many of these are imported as, *Guava jelly* and a syrup of the same fruit, besides *Guava paste* and *marmalade*, from Florida and the West Indies; the latter costs twenty-five cents a pound. *Lime-juice syrup* also comes from the West Indies, while a comparative novelty in our city, *Tamarind syrup*, comes from the East Indies by way of the Netherlands, and costs fifty cents a bottle. *Blood orange phosphate* is a popular fruit syrup, used for making a drink, and costs twenty-five cents a bottle. Neat and attractive glasses of *Bar-le-Duc*, red currants and white currants preserved separately, and costing twenty-five cents a package, and *Cerises au Marasquin*, the bright-colored French cherries in syrup, from Bordeaux, are among the imported attractions in glass, while slender glass jars containing strikingly handsome fruit, are labeled with the name of the Fabrikant and of the fruit in good German, with no suggestion, however, of where the fruit is put up. These glasses show French *marrons*, cherries glacé in vanilla syrup, strawberries, plums, prunes and pears, all of one kind, or assorted in the same jar. The chestnuts are imported; the choice fruits are grown in America, and are preserved in a rich syrup in this country by an experienced German. These jars, weighing one and a half pounds, cost forty-five cents, and two and a half pound packages readily command seventy-five cents. Assorted glacé fruits, from France, in neat paper boxes holding one pound, cost sixty cents, and two-pound boxes of glacé apricots cost \$1.25. A section of stem with *Muscat dates* attached fills a box which holds a pound; this costs twenty-eight cents. *Royal Locoum* pulled figs sell for twenty cents a pound, and the best pressed figs bring the same price. The grade known as *Extra Natural figs*, from Turkey, in their original plump form, realize thirty cents a pound. French prunes sell at twenty-five cents, Russian Imperial cluster raisins, at thirty-five cents, and Arabian dates, seeded, and stuffed with almonds, walnuts or pecan nuts, at thirty cents a pound. Preserved Canton ginger, in five-pound jars, costs sixty cents. Among many domestic and foreign nuts, salted *Pistachio* nuts, in the partly open shells, are the most interesting. These sell for fifty cents for a half-pound package.

## Poisonous Mushrooms.

THE two cases of poisoning from eating *Amanita muscaria*, one terminating fatally, which occurred recently in the city of Washington, tend to strengthen the belief that it is almost hopeless to expect that the time will ever come when a knowledge of the distinctive marks of our common poisonous fungi will be so widely spread that serious accidents need not be feared. The victim in this case was Count de Vecchi, a man of intelligence, educated in Italy, and supposed to be well informed about edible and poisonous fungi. Furthermore, there was evidence to show that he had in his possession and had apparently recently consulted a pamphlet in which the dangerous *A. muscaria* was described and figured, and yet, in spite of all this, he deliberately selected that poisonous species for his table. If Count de Vecchi could be thus mistaken, what could be expected of persons of less education and experience?

The present case should serve as a warning in several respects. In some parts of the country there has sprung up suddenly a mania for fungus-eating, which has been carried to such an extent that not a small number of persons have convinced themselves that nearly all our larger toadstools are not only not injurious, but really palatable. It is, of course, useless to question what is a matter of taste, but when it goes so far that it is seriously maintained that even *A. muscaria* is edible, as is claimed by some enthusiastic mycophagists, the present fatal case is decidedly instructive. The determination of the fungus was made by experts of the Agricultural Department, and it cannot be supposed that they were not familiar with this common species. Even were it true that *A. muscaria* is sometimes poisonous and sometimes not—and it should be borne in mind that this assumption has never yet been shown to be a fact—the present case shows that it certainly is not a species to be eaten.

As articles of food fungi belong to a quite different category from that of other substances. In the case of meat the butcher knows what he is about when he sells, and his customer in buying knows that, however he may be cheated as to price and quality, he is not purchasing what may kill him in a few hours. Fungi are rather to be

compared with drugs in an apothecary's shop, where, with some which are harmless, are others which are highly poisonous, and none but persons of special training are allowed to dispense them. The danger of mistake through ignorance is recognized and the conditions of the sale of drugs are regulated by law. In countries where fungi are largely eaten the danger of mistaking harmful for harmless species is recognized, and experts are appointed to examine fungi offered for sale. So far the comparative exemption from fungus-poisoning in this country has been due to the fact that dealers have been afraid to sell, and purchasers to buy, anything but the cultivated mushroom, *Agaricus campestris*, or, perhaps, in a few eastern cities, *Coprinus comatus*. This caution has been carried so far that, a few years ago, a gentleman in Washington who raised large quantities of a delicious native species closely resembling the common mushroom, was obliged to abandon the culture on a large scale because no dealer could be persuaded to buy his fungi in spite of their close resemblance to the ordinary mushroom.

Considering the increasing fondness for fungi in this country and knowing that it is next to hopeless to suppose that persons who are fond of eating fungi will be able to become experts in distinguishing edible from poisonous species, the time seems to have arrived when the sale of fungi should be controlled by law. During the winter months, especially in the northern states, practically nothing is sold but the cultivated mushroom, and there is no need of restricting the sale at that season. But during the summer months when, in some parts of the country, it is the custom for farmers and others to bring to market fungi which they have found growing wild, they should be compelled to sell their goods only at authorized places and authorized hours, and there should be appointed experts to examine all fungi sold. The experts could be paid wholly or in part by fees received from those selling fungi. This system has worked well in parts of France and Italy, especially in towns of moderate size. In very large cities, as a rule, the variety of fungi offered for sale is smaller than in towns situated in rural districts. Although we advise the appointment of expert examiners, the advantage to be derived thereby will not probably be so great as in countries like France and Italy. There fungi form a larger portion of the food of the poorer classes than with us. In this country the greatest danger at the present time is that the upper and middle classes, with whom it is becoming more and more the fashion to collect fungi in the fields and woods for their own consumption, will, perhaps, trust too much to chance and exceed the bounds of ordinary prudence. We are, perhaps, warranted in believing that the amateur fungus collector of the present day is attracted not altogether by the intrinsic value of fungi as food, but finds a certain pleasure in the knowledge that he is running some risk of being poisoned. However that may be, there is good reason why the sale of fungi should be guarded by law in the interest of those who neither pretend nor can be expected to have any clear knowledge of the species which may be offered for sale.

## Notes on Cultivated Conifers.—IX.

MOST of the Pines with thickened cone-scales and coarse-grained resinous wood produce their leaves in clusters of two or of three with persistent sheaths. There is, however, a small group of this section with leaves in from one to five leaved clusters and deciduous sheaths, and to this belong the so-called Nut Pines or Piñons of the arid regions of the south-western United States, northern Mexico and Lower California. There are four of these Nut Pines, all inhabitants of the United States and all small, round-topped trees, with rigid spinescent leaves, small globose cones of few scales and large edible seeds, which furnish to some of the desert Indians their principal supply of food; and they all grow in company with desert Junipers in regions too dry for other trees. Two of the Nut Pines,

*Pinus monophylla* of the deserts between the Rocky Mountains and the Sierra Nevada, and *Pinus edulis* of Colorado, Utah, New Mexico and Arizona, live in the eastern states, but grow here very slowly, giving little promise of ever emerging from their strictly pyramidal juvenile form or of producing cones. The former is interesting morphologically, as it is the only Pine-tree (with the exception of a monstrous seminal form of the European *Pinus sylvestris*) with leaves which generally appear solitary by the very early suppression in the bud of one leaf of a two-leaved cluster.

In this group, too, may be placed two alpine Pine-trees of western North America, with leaves in five-leaved clusters crowded round the ends of the branches in dense brushes, and fitly called Foxtail Pines by the miners, who often use their short stout trunks for props in the mines. The first of these trees, *Pinus Balfouriana*, from northern California, has probably not been tried in the eastern states, but the other, *Pinus aristata*, which is widely scattered at high elevations from the outer range of the Rocky Mountains of Colorado to the southern Sierra Nevada and to the San Francisco Peaks in northern Arizona, was raised in 1862 by Dr. Asa Gray in the Harvard Botanic Garden from seeds collected by Dr. Parry on Pike's Peak. A few of these plants are still left in the neighborhood of Boston, and now at the end of thirty-five years are from twelve to eighteen inches in height and interesting only in the evidence which they afford of a remarkable tenacity of life under adverse conditions.

In the group of Pine-trees with leaves in clusters of three are some of the most important timber-trees of the whole genus, like *Pinus palustris*, the southern Pitch Pine, the most valuable of all the Pines, *Pinus Taeda*, the Loblolly Pine of the southern states, and several Mexican, Californian and Indian species. None of these, however, is hardy in the northern states, where only a few of the three-leaved Pines can be successfully cultivated. The best-known here is the native Pitch Pine (*Pinus rigida*), which is widely scattered from New Brunswick and the northern shores of Lake Ontario to northern Georgia, and from the seacoast to the western slopes of the Appalachian Mountains. This tree is valuable because it can be raised more quickly and cheaply in the northern states than any other conifer from seeds scattered broadcast on the ground or sowed in shallow drills; and no other conifer grows here so rapidly on dry sterile gravels, which it soon covers with dense forests. It is often valuable, too, where the soil is poor, as an ornamental tree, and in old age it frequently becomes extremely picturesque with its dark red-brown roughened and deeply fissured bark, contorted branches and sparse dark yellow-green rigid leaves which stand out stiffly from the branchlets. To this section of the genus also belongs *Pinus ponderosa*, one of the largest and most majestic of all Pine-trees, and one of the most widely distributed and variable of the North American species. As a rule, *Pinus ponderosa* and its varieties have not proved satisfactory in the eastern states. The long-leaved California forms are not hardy in New England, although I have seen in the Hudson River valley two or three healthy specimens from thirty to forty years planted. The form of the interior of the continent (var. *scopulorum*) with short leaves in two and in three leaved clusters and small cones is hardy in the neighborhood of Boston, where it is impossible, however, to keep it alive more than a few years at a time, owing to a fungal disease which disfigures and soon destroys it. The variety *Jeffreyi* (the *Pinus Jeffreyi* of many authors), a large tree of the dry parts of northern and eastern California, with long blue-green leaves and large cones, is more successful here, although healthy plants are not common. This tree appears quite hardy in the neighborhood of Boston, but the best specimens probably in the eastern states are in Delaware Park, Buffalo, where eight trees planted in 1871 vary in height from twenty-five to thirty-seven feet, with stems measured at one foot above the ground varying from one foot nine

inches to three feet nine inches in circumference. There are two healthy plants of this variety, also, about twenty-five feet in height, in Central Park, New York, near the greenhouses on the east drive. This handsome and distinct tree can therefore, perhaps, be used here more freely than it has been, although like the green-leaved forms, it will probably always suffer more or less from fungi.

The only other Pine with leaves in clusters of three which we can hope to see established in our northern gardens is the north China Lace Bark Pine (*Pinus Bungeana*), a tree with a stout trunk divided not far above the ground into several upright secondary stems, smooth pale bark separating freely into thin scales like those of a Birch or an Arbutus, and stiff rigid yellow-green leaves. This tree is very hardy in eastern Massachusetts, where, although still retaining a bushy habit, it produces fertile cones in abundance. Probably the largest and handsomest specimen of the Lace Bark Pine in the eastern states is in Mr. Josiah Hoopes's pinetum at West Chester, Pennsylvania (see GARDEN AND FOREST, vol. vi., p. 458).

Among the Pines with leaves in clusters of two there are a number of species which are hardy in the northern states and among them are a few good park trees. The most valuable for our plantations is the Red or Norway Pine (*Pinus resinosa*). This is a tree of the far north, ranging southward only to eastern Massachusetts, where it occurs in a few small isolated groves, the mountains of Pennsylvania, and central Michigan, Wisconsin and Minnesota. In its best state the Red Pine is a tall-stemmed tree one hundred and fifty feet in height, with a trunk five feet in diameter, although more usually it does not attain much more than half that size. In the beauty of its long dark green, lustrous leaves and light red bark, and in its rapid growth it excels all the Pitch Pines which are hardy here, although a climate colder even than that of eastern Massachusetts is required to develop all its beauty. Botanically this tree is interesting as the only American representative of a peculiar Old World group of species of which the so-called Scotch or Rega Pine (*Pinus sylvestris*) is the best known in this country. This is the great timber Pine of Europe, where it is widely spread over the continent and over Russian Asia, often forming vast forests on sandy northern plains. Grown under the best conditions in its native countries, *Pinus sylvestris*, with its tall trunk covered with light red bark and picturesque crown of short and often contorted branches clothed with pale blue-green leaves, is one of the handsomest of the Pines. It was introduced into the United States early in the present century, and, unfortunately, nurserymen have found it a profitable tree to raise. Its value, like that of a good many other foreign trees which can be easily and quickly grown in nurseries to marketable size, has been extolled far and wide, and it has been largely planted all over the northern states as an ornamental tree and to form wind-breaks on the prairies and plains of the central west. Experience has shown, however, that although *Pinus sylvestris* grows in America while young with great rapidity, producing seedlings spontaneously, it soon dies from the attacks of disease and boring insects, so that trees more than thirty or forty years old are rare in this country. In European nurseries a number of monstrous forms are propagated; the most distinct of these is the variety *pumila*, a small compact shrub, the variety *fastigiata*, with erect branches, and the variety *monophylla*, on which the leaves are solitary. There are also cultivated forms with leaves marked more or less conspicuously with white and with yellow, and others with pendant branches or otherwise different from the normal in slight peculiarities.

The Austrian Pine, which is now generally considered a variety of the *Pinus Laricio* of southern Europe, has also been largely planted in the northern states as an ornamental tree. It grows here very rapidly, and, although less beautiful than the native Red Pine, in youth it is a handsome tree of good habit and rapid growth with long dark green rigid leaves. Easy to raise, the Austrian Pine, like the Scotch Pine, has been too much praised by Ameri-

can nurserymen, who find quicker profits in growing these European Pines than they do in raising the native White and Red Pines, for the Austrian Pine, although it lasts some time in good condition rather longer than the Scotch Pine, generally succumbs to the attacks of boring insects before it has lost its bushy juvenile habit, and an Austrian Pine in the United States more than fifty feet high is exceptional. The more slender-leaved Corsican Pine, the typical *Pinus Laricio*, is a handsomer tree, which has not proved hardy in New England. It may be occasionally seen in the middle states, but there is no evidence, however, in large or old specimens that this tree will really become a valuable acquisition for American plantations.

*Pinus montana*, also known in its different forms as *Pinus Mugho*, *P. uncinata* and *P. Pumilio*, is a subalpine plant of the mountains of central Europe, where it grows at elevations between 4,000 and 7,500 feet above the sea-level. Sometimes rising into a small tree, the Mountain Pine is more often shrubby in habit, with many stems decumbent below and erect above, forming broad clumps generally five or six feet in height and densely clothed with stout, rigid, dark green leaves. This plant is usually more successful in the northern states than the other European Pines; very hardy and comparatively free from the attacks of disease and insects, it is often useful for the decoration of rocky banks and knolls.

Of the value of the two eastern Asiatic two-leaved Pines introduced into this country it is too soon to speak, as they have been grown here for only twenty-five or thirty years. The first of these trees, *Pinus Thunbergii*, the Kura-matsu or Black Pine of Japan, inhabits northern China and Corea, and is extensively cultivated in Japan, where it is probably not indigenous. It is a tree sometimes eighty feet in height, with a trunk three feet in diameter and a broad head of stout, contorted and often pendulous branches, stout dark green leaves not unlike those of the Austrian Pine, and conspicuously white branch-buds. This is a favorite tree with the Japanese, who plant it on sandy coast plains and along the borders of their principal highroads. It is also used to cover arbors and to hang over the sides of moated walls, and is seen in every garden, where it is frequently dwarfed and trained into fantastic shapes. *Pinus Thunbergii* is perfectly hardy in New England. The Aka-matsu, or Red Pine of Japan (*Pinus densiflora*), is common in the mountain forests of the central part of the empire, and is seventy or eighty feet in height, with a slender trunk covered with light red scaly bark and thin light green leaves. Although an exceedingly picturesque and beautiful tree, it is rarely used by the Japanese as an ornamental plant, although it is a common inhabitant of their artificial forests. This tree, which often appears in our gardens under the name of *Pinus Massoniana*, a name which belongs to a south China species, is hardy in New England, where it produces fertile cones in profusion and is already beginning to assume its mature picturesque habit. So far as can be judged by an experience of twenty-five years, this appears to be the most promising of the two-leaved Pines introduced into the eastern states from foreign countries.

Other two-leaved Pines which are perfectly hardy in the northern states are *Pinus Virginiana*, better known, perhaps, as *Pinus inops*, the Jersey or Scrub Pine, *Pinus pungens*, the Table Mountain Pine, *Pinus echinata* (or *mitis*) and *Pinus divaricata* (or *Banksiana*). These are all eastern American species of no particular ornamental value. The least attractive of them, perhaps, is *Pinus Virginiana*, an inhabitant of the middle Atlantic states, and perfectly hardy in eastern Massachusetts. Scrubby generally in appearance, it is a valuable tree in its ability to cover rapidly sterile and worn-out soils in the middle Atlantic states. *Pinus pungens*, usually called the Table Mountain Pine from a locality where it grows in Pennsylvania, is an Appalachian species which naturally does not grow north of Pennsylvania. It is very hardy in New England, but has little to recommend it as an ornamental tree but its large,

massive, abundant cones. *Pinus echinata*, the short-leaved Yellow Pine of the south, is one of the most valuable of all timber Pines, supplying from the pineries of the upper districts of the southern states, and of Arkansas immense quantities of valuable lumber. It finds on the Atlantic coast its most northerly home on Staten Island, New York. This noble tree exists in the Arnold Arboretum, but evidently is not yet at home here. *Pinus divaricata*, which is the most boreal of the Pine-trees of eastern America, although it attains its greatest size and beauty only in far northern regions, flourishes in eastern Massachusetts, and is always interesting, if not beautiful, with its short, stout, falcate leaves spreading from the base, and erect cones incurved to the branches.

The Lodge Pole Pine (*Pinus contorta*, var. *Murrayana*), which grows over all the mountain ranges of the north-western and central mountain regions of the continent, and is the most widely distributed of the North American Pines, is chiefly interesting in the power of its seeds, securely guarded in tightly closed cones until fire releases them, to germinate on burnt soil. Thanks to this power, the Lodge Pole Pine has been able, not only to maintain itself against the inroads of fire, but to increase the area of its possession until it seems destined to become in the future the sole inhabitant of western forests. Introduced from Colorado into the Arnold Arboretum about twenty years ago, the Lodge Pole Pine has proved hardy and produced its cones here, but, like other dry country conifers, it suffers from fungal diseases and gives no promise of permanent success.

C. S. S.

#### Autumn Fruits in the Pines.

AS autumn advances in the Pines the fruits are continually disclosed, and show a wealth of color only equaled by the many-hued leaves of the trees and shrubs. The bright scarlet-red fruit of *Ilex verticillata* is to be seen everywhere in the low thickets, and of *I. lævigata* also, though it is less common. The fruit of the latter species ripens before that of *I. verticillata*, and is also larger and more scattered on the limbs and twigs. The foliage is still green on both species, and the showy berries are specially beautiful among the leaves. The Ink Berry (*I. glabra*) with evergreen leaves and black fruit, is abundant in all damp places in the Pines. Our American Holly (*I. opaca*) is unusually attractive this fall. The berries are not as brilliant as those of the deciduous members of the genus, but the handsome foliage, which remains as long as the fruit, more than compensates for the less vivid color.

*Magnolia glauca* is one of our best and most abundant trees. It is almost an evergreen in the Pines, and young trees especially hold their leaves until late spring. Its handsome cone-like red fruit has appeared all summer long and still shows here and there among the large, shining dark green leaves. The Flowering Dogwood, too, is yet holding its clusters of bright red drupes, more attractive even than its showy flowers. A wealth of Rose hips decorate the low bushes along country roadsides and in out-of-the-way places, and in the damp Pines the tall Swamp Rose (*Rosa Carolina*) reaches above our heads and is thickly set with its flattened globular fruits. One form of *Pyrus arbutifolia* has red berries, which it still retains, and these will provide winter feasts for the birds. The orange-colored pods of the Bittersweet (*Celastrus scandens*) are now opening, and disclose the bright scarlet seeds. A few years ago *Smilax Walteri* could have been seen here with its red fruits, but it has disappeared from this locality and its former home is now occupied by cultivated plants.

Among handsome trailing vines seen here, which bear bright fruits now, is the Cranberry (*Vaccinium macrocarpon*). Among the clean, damp sphagnum it sometimes has berries of the deepest crimson, while others are light red, and some are white on one side and deep pink on the other. Long stems bearing this multicolored fruit are sin-

gularly ornamental when mingled with the glossy leaves of neighboring low shrubs. Here and there we find dense patches of the creeping Partridge Berry (*Mitchella repens*) with small, round leaves strung along the stem in pairs, interspersed with the scarlet double berries. Both leaves and fruit remain fresh and bright all winter long. The Creeping Wintergreen (*Gaultheria procumbens*) with its red aromatic fruits and shining fragrant leaves, is common in the damp Pines.

Not only red fruits abound at this time, but many others of less conspicuous color, though equally handsome, are found in the Pines. The fruit of the Bayberry (*Myrica Caroliniensis*) covered with white wax and mingled with its fragrant leaves, is ornamental and pleasant to handle. These dry, waxy nuts are a favorite food of birds at this season. In my wild garden there are several groups of these shrubs, the stems of which early in autumn were almost covered with the white drupes. But the birds settled on the bushes in flocks and stripped them clean, not leaving a berry; the fragrant leaves will remain all winter.

The berry-like blue fruit of the White Cedar (*Cupressus thyoides*) is also ornamental. Its sweet pleasant taste attracts robins, bluebirds and cedar birds, which often eat all the fruit on a tree before cold weather sets in. The black fruit of *Smilax Bona-nox* is quite effective mingled with its shining green leaves, and so is the fruit and foliage of several other species of this neglected genus.

The Fringe-tree (*Chionanthus Virginica*) has small olive-like fruits which remain green most of the summer, and take on a purple hue late in the season. These remain in autumn until the birds take them, but they are less greedily eaten than many other fruits. The Virginia Creeper has been beautiful all through the fall with its crimson foliage and clusters of bluish black berries, which the birds specially like. The Common Tupelo (*Nyssa sylvatica*) is still magnificent with bright crimson leaves and oval bluish fruit in clusters on the end of a slender stem. The Frost Grapes are highly ornamental in the right place. The leaves have a delicate texture and are deeply lobed and bright green on both upper and lower surfaces.

The fruits of some of the Persimmon-trees in the Pines ripen in September and October, and are excellent, with no astringent taste. On most of the trees the fruit is not edible until after exposure to sharp frost, and even then it is not so pleasant tasting as the earlier fruits. It is remarkable that this common Persimmon (*Diospyros Virginiana*) is not cultivated, for the tree and foliage are both handsome, and the fruit delicious.

The Pokeweed, which grows everywhere, can be made a most striking and effective decorative plant. With care and rich soil it will attain a height of ten feet or more. Its red stem and fine large leaves, exempt from insect predators, are ornamental, and its long racemes of white flowers with ten stamens and ten styles are more handsome than many exotic plants which are given a place in our gardens. The blossoms appear all summer long until sharp frosts cut them off; and the racemes of rich purple berries are also handsome. Any one who cares to study the ways of birds will welcome a thriving plant of Pokeweed near his window. The birds are specially fond of the fruit, and in no way can one more readily note the behavior of the different birds than here. The bluebird has delicate manners when he dines; he is deliberate and dainty, taking a berry and then pausing and making some comment to his mate or children. The family remains united throughout the autumn and takes its meals together. The catbird has quick, jerky movements and eats more rapidly than the bluebird, but not so greedily as the robin, who gorges, and then stretches himself up in a pompous way, his red breast dyed with the purple juice. After looking about a few moments he hurriedly takes more, and only leaves the berries to go to the lawn with his head to one side, as he listens for earth-worms or white grubs, which he pulls from among the grass-roots.

Vineland, N. J.

Mary Treat.

## New or Little-known Plants.

### *Alnus tinctoria*.

UNDER this name an Alder was sent several years ago to the Arnold Arboretum by Mr. Veitch, who probably had raised it from seeds collected in Japan by Maries, as I have seen the same tree in Yezo, and the plants raised from seeds which I brought from that island five years ago are identical with Veitch's *Alnus tinctoria*, a name which, although it has been more or less used in gardens, appears to be still unpublished. On the island of Yezo this Alder is a shapely tree from fifty to sixty feet in height, with a trunk often two feet in diameter, growing there on low slopes in rich moist ground, usually at some distance from the banks of streams, which are generally occupied in southern Yezo by *Alnus Japonica*. It has been considered by the Japanese botanists Spach's variety *hirsuta* of *Alnus incana*, of Manchuria and Siberia, and it is possible that this view is correct, although, for lack of proper material, representing the different species and varieties of Asiatic Alders in American herbaria, it is impossible to form a correct idea on this subject, and the object of this note, and of the figure on page 473 of this issue, made from specimens gathered in Yezo, is to call attention to a promising ornamental tree.

The leaves of this Alder, which, until something more is known of the Manchurian species, had perhaps best be called *Alnus tinctoria*, are oblong, obtusely wedge-shaped at the base, coarsely doubly serrate, or often incisedly lobed above the middle, and clothed below with soft, close, rufous pubescence, which also covers the upper side of the slender midribs and primary veins; they are thin and membranaceous, from four to six inches long and from three and a half to five inches broad, dark green above, pale below, and are borne on stout petioles an inch and a half in length. The flowers I have not seen, but the buds of the staminate catkins are an inch and a half long and a third of an inch broad, and are borne on stout peduncles from one-third to one-half of an inch in length. The fruit is half an inch long and about a third of an inch thick, so that the leaves, the buds of the staminate catkins and the fruits are much larger than those of any of the European or North American forms of *Alnus incana*. The stout, somewhat flattened branchlets marked by only occasional pale lenticels and covered during the winter by a glaucous bloom, and the much larger bright purple-red winter buds, appear very distinct from those of *Alnus incana*.

Several of the plants raised from seeds which I brought from Japan in 1892 are now twelve feet high, with perfectly straight stems from five to six inches in diameter at the base and furnished with well-balanced, vigorous branches. Shapely and handsome now, they look as if they would grow here to a large size and prove valuable ornamental trees.

## Foreign Correspondence.

### Chrysanthemums.

THE annual exhibition arranged by the National Chrysanthemum Society was held this week in the Royal Aquarium, Westminster, and was open three days. In the extent of the collections and quality of the flowers it was considered to be the best exhibition ever held in London, or, indeed, anywhere else. Years ago specimen plants were the principal feature of this and similar exhibitions, but now it is almost entirely a display of cut flowers arranged either on trays, in vases, or in various floral decorations, such as crosses, wreaths, etc. I noted last year the extraordinary progress made in the Japanese section compared with the other sections, and this year the popularity of this big fantastic-flowered section is greatly emphasized. Thus, of cut flowers shown for prizes there were over one thousand blooms of Japanese varieties staged, whereas the

Incurved section numbered less than five hundred, while all the other sections together would not exceed the latter number. When it is borne in mind that the flowers of the

The crowd was always thickest in front of the stages where the Japanese flowers were, and the conversation of the thousands who visited the exhibition was generally directed to

Fig. 59.—*Alnus tinctoria*.—See page 472.

Japanese section are from eight inches to a foot in diameter, the display a thousand blooms would make can readily be imagined. And these figures do not include the large collections of blooms shown in groups by trade growers.

the enormous size, colors and other attractions of the flowers of this section.

While many of the old favorite varieties held prominent positions among the most successful exhibits, there were

many new varieties also, and some of them were voted the highest honors. A list of the varieties which comprised the premier collection of forty-eight cut blooms of the Japanese section comprises Madame Carnot, Etoile de Lyon, Mrs. W. H. Lees, Monsieur de la Rocheterie, Baronne Ad. de Rothschild, J. Brooks, Mrs. C. H. Payne, Vivian Morel, Monsieur Panckoucke, Eva Knowles, Pride of Exmouth, A. H. Wood, Lady Hanham, Simplicity, Australie, Yellow Madame Carnot, Phœbus, Mrs. Dewar, Julie Scaramanza, Mutual Friend, Mrs. G. Carpenter, Monsieur Hoste, Charles Davis, Mrs. Charles Blick, Monsieur Chenon de Leché, Australian Gold, E. Molyneux, Mrs. J. Lewis, Monsieur Gruyer, Edith Tabor, Monsieur Hoste, Lady Ridgway, Mrs. Weeks, Monsieur Ch. Molin, Colonel Chase, Sunstone, Mademoiselle M. A. de Galbert, Modesto, Madame M. Ricoud, Baron Tait, Niveus, Mrs. Briscoe-Ironside, Madame Gustave Henry, N. C. S. Jubilee, Miss Elsie Teichmann, Robert Powell, Robert Owen and Viscountess Hambleton. This collection was shown by Mr. W. Mease, gardener to A. Tate, Esq., Leatherhead, one of the most successful growers and exhibitors of Chrysanthemums. The prize for six blooms of a white Japanese variety was awarded to magnificent flowers of Madame Carnot; Mrs. C. Blick being second and Madame Carnot again third. The yellow sport of Madame Carnot, called J. G. Warren, was awarded the medal for the best flower of a Japanese variety in the whole exhibition. In the class for six flowers of a Japanese-colored variety, Phœbus (yellow) was an easy first, Edith Tabor (yellow) being second and E. Molyneux (crimson and gold) third. Other Japanese varieties which were of marked excellence were Western King (white), Hairy Wonder, Elsie Teichmann and Australian Gold. The feature of the whole exhibition, however, was Madame Carnot, which was prominent in every collection, and also figured largely in the groups, fifty magnificent blooms of it being conspicuous in a most artistically arranged group of cut flowers in vases shown by Mr. Norman Davis.

The Incurved section, although eclipsed by its larger-flowered, less formal sister, was represented by some beautiful flowers. The magnificent yellow, Charles H. Curtis, was by far the best of the varieties shown, while the white Madame Ferlat, the purple Miss Dorothy Foster and the blush-white Lady Isobel were worthy companions. The premier collection of thirty-six blooms was shown by Mr. Mease and comprised the following: Duchess of Fife, Violet Foster, J. Agate, Dorothy Foster, Major Bonaffon, Mrs. R. C. Kingston, William Tunnington, Lord Alcester, Lady Isobel, Robert Petfield, Charles H. Curtis, Ma Perfection, John Doughty, Empress of India, Lucy Kendall, M. P. Martignac, Queen of England, Violet Tomlin, John Lambert, Lord Rosebery, Golden Empress, Globe d'Or, Jeanne d'Arc, Robert Cannell, Princess of Wales, Brookleigh Gem, Empress Eugénie, George Haigh, Bonnie Dundee, Noel Pragnell, Princess Beatrice, Mrs. Hepper, Alfred Salter, Mrs. Heale, C. B. Whitnall and Miss Haggas.

The best collection of twelve varieties of the Anemone-flowered section comprised Mr. H. Gardiner, Sir Walter Raleigh, Robin Adair, Mademoiselle Cabrol, Queen Elizabeth, Nelson, Caledonia, Owen's Perfection, John Bunyan, W. L. Astor, Enterprise and Reiche Lyonnaise. Although wanting, perhaps, in those characters which make the Japanese varieties so popular, yet I consider that these Anemone-flowered sorts are the most remarkable of all the races developed from the wild Chrysanthemum, the central florets in many of them being like a compact cluster of the flowers of an Erica, such as *E. hyemalis*, surrounded by a ruff or collar of ray-florets.

The Hairy Chrysanthemums are growing in favor here, the best of the varieties raised so far, namely, Hairy Wonder, being shown in fine form in several collections of cut blooms. Other varieties shown were Princess Ena, Mrs. Godfrey, White Swan, Mrs. Dr. Ward and Vaucanson.

The single-flowered varieties have many admirers since the introduction of Mary Anderson and Jane, two of the

most beautiful of all Chrysanthemums for pot specimens. I noted the following among the cut flowers shown: Lady Churchill, quilled, brick-red and gold; Evan Cameron, white; Miss Braithwaite, deep crimson, six inches across; Mrs. B. Ware, yellow, with drooping florets; Oceania, pale blush-pink; Rev. Rambrey, crimson; A. T. Simmons, yellow. If I had to be limited to the cultivation of three Chrysanthemums I should ask for Mary Anderson to be one of them. It is charming with us this year both in the conservatory and in the open borders, where now (November 12th) it is crowded with flowers.

Specimen plants were represented by only a small number of examples, which, however, were excellent in their way, enormous half-globes or standards, with the flowers all spaced out equally and staked or wired separately. The best of them was a gigantic semiglobular plant of Colonel W. B. Smith bearing over fifty flowers, every one of which was almost good enough for the exhibition table. Madame Carnot, Gloriosum, John Shrimpton and Florence Percy were also represented by big well-flowered specimens.

Exhibitors, in London at any rate, have yet to learn how to appreciate the Chrysanthemum when grown in a more natural way. The big flowers necessary to win prizes when shown singly on trays are wonderful examples of the cultivator's art, but such flowers can only be grown at the expense of the natural beauty of the plant, which, in fact, is often made to concentrate all its energies on the production of one bloom. There is also a danger of breeders neglecting altogether the habit and leaf characters of the plant in their pursuit of the big exhibition bloom. Many of these big-flowered varieties are worthless when grown as bushes to produce a dozen or so of flowers. We want bushy Chrysanthemums for the decoration of the conservatory rather than the long-legged, one-flowered monstrosities such as one sees in the gardens of those cultivators who grow chiefly for exhibition. The thousands who now grow the Chrysanthemum, from the royal gardener to the poorest cottager, prefer a plant that is a picture as a whole rather than one that is remarkable only for the enormous size of its flower when grown on the "extension" system. However, we have plenty of varieties, old though most of them are, which serve the former purpose admirably. As *The Gardeners' Chronicle* remarks: "It seems but a few years since the first really good exhibition was held or since breeders' attempts to produce larger and more attractive flowers. But the work has gone on apace, the strides have been rapid and every one is astonished at the result."

London.

## Cultural Department.

### Greenhouse Cultivation for Amateurs.

GARDENING, with a general collection of plants in the open and under glass, is a rather continuous experience, but when the days are shortened, the outdoor labors are past and the greenhouse made ready for a new season, there is a comparatively care-free time of a few weeks—for the amateur, at least. It is well to recognize at this season, that plants, as well as man, appreciate a rest, and patience, rather than haste, is now the proper state of mind in the matter of greenhouse treatment. Surplus artificial heat with forced growth under the present lowering skies is sure to result in weak plants with a prison-like pallor, for which a few extra flowers are no compensation, not to say anything of insects, which are sure to riot on the weaklings later.

It will suffice to define my greenhouse operations as strictly amateurish if I record that now, on November 15th, there is no fire-heat in the house. The stove has been lighted a few times, but not enough heat has yet been applied to make the plants at all tender or liable to injury by draughts of cold air. Of course, this season has been exceptionally warm, but my usual practice is to avoid all artificial heat until I am forced to start it, and wait with more or less patience for clearer skies and settled weather which midwinter is sure to bring. Like all small greenhouses, mine warms up too rapidly and cools off as suddenly; but this is a detail without serious effect on plants. No place in the world has a really constant temperature, and the insistence on fixed temperatures for plants under

cultivation is somewhat misleading. Too many flower fanciers and owners of small gardens are deterred from having a small greenhouse by the fancied expense and the supposed difficulty of growing plants under glass, this latter idea being formed from reading long detailed cultural directions for plants often grown as easily as Beans. The practical fact is, as the least reflection will show, plants under glass should be as easily and successfully cultivated as those grown in the open. Each kind of gardening has its problems. The average plant cultivated in the garden will grow fairly well without much attention, but there are numerous species which test all one's skill and patience, and are almost impossible to cultivate successfully under the unnatural conditions which prevail in the ordinary garden. In the greenhouse the problems are different, but the conditions are very much under the control of the cultivator, and any one who understands plant-growth should have fewer failures indoors than outside. Plenty of good fresh air properly warmed and a judicious use of the watering-pot are the first simple requisites to successful cultivation of plants under glass. A man whose plants are in such condition that when the ventilators are open they become covered with mildew, or when closed are infested with a crop of thrips, is outside his vocation.

Commercial flower growers force their plants and grow them at high pressure, with the one object of securing a crop. Generally they succeed, but the plants are exhausted, and it is a constant struggle with most unnatural conditions, and not a practice to be followed by the amateur, to whom individual plants are valuable, if common, and to whom repose and pleasure are somewhat synonymous. What an amateur will grow in his greenhouse is as often a matter of chance as of taste, and usually three or four times as much is grown as the house will comfortably hold. In all large towns nowadays the florists' flowers, as roses and carnations, are plentiful, and it does not seem worth while to give up the greenhouse to these. Usually it will be found most satisfactory to grow rather unusual plants or those not seen in the shops, and supplement the ordinary contents of the home with potted Dutch bulbs, to be brought in during the winter.

Insects are always with us, but they affect some plants more than others. It is scarcely ever worth while to continue to grow a plant that persistently collects most of the insects in the house, as some plants will. Palms are the only insect accumulators which I tolerate. My list of plants is apt to change from year to year, but at present there is a bench of Orchids, and some of these plants suspended; a lot of miscellaneous plants, including Begonias, Palms, Crotons, Eucharis, Grifinias, Irises, Cacti, Sedums, Marantas, to mention a few which occur to me; a few climbers; a bed of Ferns and one of Violets; and a lot of odd bulbous plants in various states of activity.

Not all the plants in this collection kept under one roof will grow into specimen plants; but they will serve to help the winter pass so pleasantly that I feel impelled to urge all amateurs to provide themselves with some structure fairly well adapted for plant-growth in winter, so that it is well lighted and properly heated. Without these conditions the cultivation of plants in winter does not seem worth the struggle. A conservatory kept cold, clammy and stagnant because there is no heat to use in keeping pure air in circulation is a most depressing example of what to avoid.

Elizabeth, N. J.

J. N. Gerard.

### Autumn Protection.

TO the possessor of a garden autumn is almost as busy a time as spring, though the work is different and not so interesting. All planting should be finished by the first of November, as there is not time enough thereafter for newly-planted subjects to get established before cold weather, and there would thus be no reserve force for the plants to draw on during winter. After that date it is better to postpone planting until spring, or if plants arrive late, to store them in a cellar or other suitable place until spring.

In the garden many plants that are classed as hardy are not trustworthy in this respect. They may pass through a season or two without damage, but will be injured or killed in an unusually severe winter, or a normal winter after a wet and sunless autumn. The past two months have been favorable to the ripening off of growth made during the past summer; this is fortunate for the plants, for if the autumn had been sunless many plants would have been killed this winter.

If there is any doubt about Evergreens, Rhododendrons especially, we always protect them by placing Pine or Spruce boughs between the plants. Formerly we covered the plants

with a thatched roof of branches, but they are now too high to protect in this way. We find that if the branches are disposed through them so as to ward off the sun's rays in the early spring months scorching is prevented. The boughs should remain until after the first hot days in April, which most cultivators agree is the critical period. We bank two feet of dry forest leaves about the roots of the Rhododendrons early in November or before that time. These are not removed in spring, and the vigor the plants have taken on under this treatment is surprising. They act as a mulch to keep the soil moist. They are eventually taken down by the earthworms, and are just the kind of food that is good for the plants.

Hardy plant borders have now been trimmed of all the top growth, and this is the time to make preparations for vigorous growth next year if the soil needs replenishing. Last fall our borders were covered with about six inches of leaf-mold, as this material was at hand. It was left on this summer, and every plant came up through it with a surprising vigor. Two seasons are necessary for leaf-soil to become properly decomposed; the decomposition may be hastened by the addition of lime, but it would not then be available for use indoors for Ericaceous plants, or for Rhododendrons in the border, as lime is fatal to all plants of this order, and, in fact, to all that have fine hair-like roots. In the absence of leaf-soil, well-rotted manure may be safely used on borders; in gardens this is almost as scarce an article as leaf-mold, as it is generally desirable to use it before it reaches the stage of mere decomposed vegetable matter; but the use of any but old well-decayed material is not desirable.

It has been generally supposed that Lilies dislike manure in the soil, and these plants are often almost starved. It is true that manure should not be placed near the bulbs, as it often causes decay. This is especially true of newly-planted bulbs; these are sometimes bruised, and the elements of decay are present, and with but little encouragement become fatal. In the case of established bulbs, however, it is necessary to provide a rich stimulant to bring them into luxuriant flowering. If this is applied now as a top-dressing the improvement will be marked next year, and the application is likely to be made annually. Lily-of-the-valley beds are also now given their usual winter covering, preferably of leaf-soil. I find that a destructive fungus is likely to attack these bulbs if manure is used. A long succession of these flowers may be had out-of-doors by carefully arranging the beds with regard to exposure to the sun in spring, and by regulating the covering. We had good flowers last summer a month after the first came in, from a planting under the shade of Pine-trees, where the frost did not thaw out until late. Lily-of-the-valley is one of the few subjects that will thrive admirably under Pine-trees; I have seen them growing wild in such a location.

If Narcissus are grown by themselves in a separate border it is necessary to give them a good protective mulch. It will be found that the young shoots are well started already, and if as sometimes happens, snow and frost come late, they will even appear above the ground and be hurt when cold weather sets in, or late in spring before the arrival of genial weather. If they are covered now this will serve also as a fertilizer in spring, and will serve also to nourish the crop of annuals which will follow the Narcissus for a late summer display. Last season we planted Gladioli between the rows of Narcissus; this was even more satisfactory than Asters, or annuals which cover the ground more.

Coniferous trees and shrubs, such as the Retinosporas, Juniperus, Thuyopsis dolabrata and the Golden Yew need protection from the sun. We find these perfectly hardy in the most exposed situations if they are sheltered from the hot sun when frozen. Young trees of Sciadopitys and the Nordmann Fir are also apt to suffer from this cause. The latter will lose its leader year after year when young if not protected, and the Japanese Silver Fir (*Abies firma*) is sure to be hurt in a sunny exposure. The branches of Norway Spruces are useful as a screen and save choice trees from damage; these must be firmly placed in the soil about the tree before the ground is frozen or the storms will displace them.

Young Magnolias that have been set out recently ought to be given some shelter for a year or two. We lost almost the whole of a collection two winters ago. Well-established trees were killed to the ground in some cases, and the strong shoots now sent up are even more liable to injury. Magnolias, which are so beautiful and so hard to get established, should have shelter for a year or two after planting.

Hardy Roses are so called, we presume, because they do not die off at once the first winter. We find that a very short list will include all that are iron-clad, but the lives of Roses can be prolonged if the earth is drawn up about them at least

a foot high. This banking will also attract the snow and thus be a help. Roses are quite apt to die to the ground if they are unprotected; if straw litter is used it will attract the field mice and these are worse even than frost, for they usually girdle the plants down to the ground-level.

A garden would lose half its charm were not these precautionary measures needed. They keep us interested in the well-being of the plants, and protective measures are never lost labor. It is better to be safe than regretful, and this is the time to get on the safe side.

South Lancaster, Mass.

E. O. Orpet.

### Wintering Bedding Stock.

**B**EDDING Stock has little decorative value at this season, and it is often a problem how to care for it without taking up too much useful space. In some instances we must propagate in the autumn to the full extent of next season's requirements. All the tricolor, as well as many bronzy-leaved Geraniums, are of slow growth, and it requires care and work to make good plants from cuttings taken in the autumn. *Nierembergia frutescens*, an uncommon but graceful little plant which gives an abundance of pale blue, saucer-shaped flowers throughout the summer, should be grown along through the winter to get good plants, and this is the case with the dwarf yellow and purple Lantanas. We take up the old plants; in time they make neat bushes and standards of these plants are a most attractive feature in the flower garden at Wellesley. The yellow variety with an undergrowth of *Nierembergia*, or dwarf Lobelia, makes an effective bed.

Plants used for subtropical effects must either be held over or propagated early to get plants large enough by planting-time. Those which need a resting season, as well as others which make little growth, can be stored in cool houses or fairly light pits. These include Grevilleas, Coprosmas, *Dracænas*, Lantanas, Acacias and Australian *Dracænas*. *Abutilons* are less hardy and need a more genial temperature. For a succession we start seeds of *Dracænas*, Grevilleas and Eucalyptus after the days begin to lengthen, and put in cuttings of the other sorts. A few old plants of *Salvias* give us all the cuttings we need. It is not necessary to take up more room with them until spring-time, as cuttings root quickly and soon make good plants. With the common tall *Salvia splendens* we would not even take cuttings, as it is more convenient to propagate from seed, but we have a selected dwarf variety which has proved to be uncertain from seeds. Common bedding Geraniums are stowed away on shelves overhead, but not more than half of the number we need are put in, as we take the tops again in February. A very few *Coleus* are required to give an abundant supply of plants. Cuttings taken in the autumn are preferred to old plants, for the latter are liable to be infested with mealy bug. But by taking the tips only of plants free from insects we keep our stock clean. A few plants of *Alyssum Little Gem* will give plenty of cuttings, but these must be started at once to get a good stock of fair-sized plants. Different methods are employed to propagate these plants. Some cultivators take up old plants, divide them in spring and put them in hot beds. This is as good a plan as any, for no growth is made until they are subject to bottom-heat. Still it is little trouble to take cuttings, root them in August and hold them over on shelves in a warm house until spring. *Heliotrope* and *Ageratum* may be treated in the same way as *Coleus*. Cuttings put in in March make good plants. Old stools of *Heliotrope* and *Ageratum* have given us quantities of flowers for cutting during winter, and as these have been appreciated we are growing a few specially for this use. The variegated *Stevias* make pretty decorative plants for which we find use during the winter.

Verbenas, once represented by a long list of named varieties which had to be increased by cuttings taken from kept-over plants, may now be classed with Zinnias, Asters and other annuals to be sown in early spring. There are now so many fine varieties of *Begonia semperflorens* available for bedding, which can be raised from seed, that few people take the trouble to keep over old plants. I have known seeds of these to retain their vitality through the winter and come up in spring. At Newport, Rhode Island, it is quite common to find thousands of mixed seedlings in beds where these plants grew the year before. *Vinca rosea*, one of the best of summer bedding plants, comes best from seed, but the seeds must be fresh and there must be a good bottom-heat to start them. *Caryopteris Mastacanthus* has for two seasons been one of the best plants for autumn bedding. It is quite easily grown from cuttings. Dwarf blue Lobelia, once raised from cuttings, is now to be had in established strains from seed.

Wellesley, Mass.

T. D. Hatfield.

**Iris alata.**—This Iris, sometimes known as *I. scorpioides*, a south European species, is now in flower in a cool house, and marks the beginning of a new season of this great family. Its flowering is, however, sometimes anticipated by that of *I. stylosa*, a species which, while hardy in this latitude in somewhat sheltered quarters, is preferably grown under protection, for we seldom have such favorable seasons as the present for plants which flower naturally in October and November. *I. alata* is a bulbous Iris with thick persistent, but not perennial roots, new ones being produced each season as the new bulb is formed. It is an easily managed plant as far as the production of the first flowers, as it starts promptly into growth and flowers as well in a pot as when it is planted out, which is not the case with some of the family. The plants must, however, be carefully ripened up in the warmest and sunniest spot available. The flowers vary somewhat, but are usually light purple, marked with orange on the ridge.

Elizabeth, N. J.

J. N. G.

### The Forest.

#### Forestry in Women's Clubs.—II.

**C**IVICS have in the past few years had serious attention in women's clubs, and in Pennsylvania forestry, educational interests and municipal improvements receive special consideration. As indicative of the common interest in forestry it is interesting to note that on October 27th, a day in advance of the meeting of the Federation of Women's Clubs in New Jersey, and entirely independent of the action of that body, forestry proved to be one of the most popular subjects at the annual meeting of the State Federation of Women's Clubs of Pennsylvania, held at Harrisburg.

Miss Mira L. Dock, of that city, known to readers of GARDEN AND FOREST through her numerous contributions in articles and illustrations, spoke on Our Forests and Their Utility and Beauty, and described her experiences in a recent tour of observation of woodlands in seven counties of Pennsylvania. The section visited was selected because it represented average, and not extreme conditions, and topographic observations and close study of special features were accomplished in extended drives and walks. Two conditions shown from these examinations were the extreme scarcity of good water and the unkempt condition of the hamlets, villages and towns, both conditions being due to an indifference that has almost ruined the beauty and healthfulness of many portions of Pennsylvania. Almost everywhere an interest in public improvements was noticed, and in each place some one person at least was thinking of a better water-supply, of village improvement or of the great waste of timber, and the growth of sentiment in favor of forestry was very marked. The enactment of the last Legislature of Pennsylvania regarding forest fires was universally approved, and the only criticisms heard regarding the act creating State Reservations of 40,000 acres each at the headwaters of tributaries of the Ohio, Susquehanna and Delaware rivers, were that they were not sufficiently large to insure safety from floods, and that more forest-land should be set aside.

The special interest of Pennsylvania forests in the variety, size and beauty of native trees, in rich forest undergrowth and in botanical interest was sketched by Miss Dock, who said that in the first half of the last century many interesting and valuable trees and plants, mostly from the forests of eastern Pennsylvania, were taken to England. The larger part of these were sent by John Bartram and Humphrey Marshall, both Pennsylvanians born and bred. These two men not only sent valuable American plants to Europe, but they and William Hamilton, of Philadelphia, from his country-seat, now Woodlands Cemetery, in Philadelphia, introduced into this country many valuable species from Europe, among them the Norway Maple, Horse-chestnut and Lombardy Poplar. The first Rhododendrons ever seen in England were sent from the Blue Mountains of Pennsylvania about the time that George Washington was born. Not only is the vegetation in Penn-

sylvania varied, but Pennsylvania is the great meeting-ground for species from northern and southern latitudes. The Catalpa from the west meets the Holly from the coast; the Locust and Magnolia from the south meet the White Birch and Red Spruce from Canada.

In the middle of the last century Peter Kalm, a Swede, when sent over to study forest resources in eastern America, wrote home, "They treat their forests very roughly." The forests of Pennsylvania were once considered inexhaustible, but reckless cutting, fires and floods have ravaged them. Just how inexhaustible a great forest is may be learned if we look at the new state of Washington, where last spring an act was brought before the Legislature declaring that by reason of the lavish waste of valuable timber resources, "an emergency exists," and a law for the protection of forests was presented, to go into effect immediately upon receiving the signature of the Governor.

Miss Dock said two problems of this time are: Can we restore our Forests? Can we maintain our water-supply? These questions forestry tries to answer. Forestry is not simply a love of trees, nor planting them on Arbor Day and then forgetting them, nor above all is it a science or art that would prevent the cutting of trees. An interest may develop from any of these sentiments, but above all else true forestry is business. It means treating a forest as Mr. Cary says, as a field and not as a mine. Timber is a crop that takes from fifty to two hundred and fifty years to ripen and the fields where it grows are hundreds of miles in extent and often lie at considerable elevations. A good farmer keeps his grounds in such a condition that crops may follow each other with perfect regularity, and if his farm lies at different elevations he sees to it that the wash from the upper fields shall not be harmful to the lower fields. In farming when a farm runs down it principally affects the owner. In timber cutting it is just the reverse. The loss and destruction increase in area and extent the farther one travels from a deforested country. The way to understand forestry is to avoid books about trees only, and to study topography, hard and soft rocks, catchment areas and drainage systems; to learn about such minor industries as shingle-making, wood pulp, match factories, etc.; to go into a lumber-camp and see the great expense the lumberman is put to. Then one is in a position to understand that there is a great deal to learn about the subject.

The amount of forest-products proper required in the arts and manufactures can only be faintly realized by long study and much measurement. Take one industry alone, the supply of hemlock bark for tanning purposes: about fifteen million dollars' worth of hemlock bark is needed annually in this country, and Hemlock-trees of the required size are from one hundred to four hundred years of age. Besides the great industries that require timber of large size, there are countless minor industries of which we have daily evidence in the small articles that we need continually and use thoughtlessly.

The second economic factor, water, is of equal importance with the timber supply. All forested areas serve as reservoirs for the collection, storage and slow distribution of the rainfall. Where there is forest-cover from three-fourths to four-fifths of the rainfall under ordinary circumstances percolates slowly into the earth and is returned, through springs and by transpiration, to the vegetation. In a deforested area from three-fourths to four-fifths of the rainfall is immediately carried off by streams, that from mere rivulets, may in an hour become destructive torrents, or, to quote a railway man at an up-county station, "now that the trees are cut away as soon as it rains the floods are on us." There always have been and probably always will be freshets, but what forestry tries to avert are calamitous floods. These are not only destructive to commercial interests throughout their course, but no conditions are so detrimental to health as extreme alternation of low and high water. Low standing water is favorable to the propagation of germs and high

water disseminates them to be deposited over wide areas as the water subsides. While water under certain circumstances does purify itself it should be a matter of public interest to inquire into typhoid and other fevers at the headwaters of our streams.

The great industry of mining also depletes the water-supply. Everywhere in coal mining when a new vein is opened it means the disappearance forever of any spring so situated that its waters can be diverted to this easy mode of exit. Once in the mine it becomes so impregnated with sulphur that it cannot be used afterward for household purposes, and in the mining regions, even more than in the lumber country, owing to the large population the forest-cover is needed to conserve all the water possible. Another direct source of loss to individuals and the state of Pennsylvania is the great aggregate of territory, almost four times the size of Rhode Island, of so-called agricultural land, that is yearly decreasing in value. Through the hill and mountain country everywhere roadbeds are torn out, fields seamed and scoured by the wash from nearly perpendicular farms clinging to bare slaty hilltops, and taxation for road repairs and bridge building has become a great burden. It is one of the compensations of Nature that this very land which is unfit in its present condition for agriculture affords congenial soil for some of our most valuable timber-trees to reach their best condition. The Forestry Commission and Board of Agriculture hope that private judgment and public opinion will soon see to the reforesting of these lands, so that they may in time become a source of revenue, instead of loss. In some portions of Germany instead of heavy assessments for bridge building, etc., not only the city expenses are paid, but householders actually receive dividends from the municipal woodlands.

How can a widespread interest be aroused and what of practical value can be accomplished by women's clubs? Everything may be done by taking one thing at a time, and can be accomplished by developing the now latent interest in the beauty of our forests. From an indefinite feeling and indeterminate action, we may have definite ideas and determinate activity by beginning with a study of the local and special, and in time an interest will be aroused in forestry in general. In the last century one young girl of twenty in South Carolina organized, where other planters had failed, the industry of Indigo-planting, that brought millions of dollars into her Province through her unaided pluck and determination. What may not result from concentrated effort of the Federation of the Women's Clubs of a state! Not a village or town of Pennsylvania but has in its vicinity at least some one point of beauty that fifty years from now may be lost beyond recall, which preserved now for a playground or park, would for all time be an object of pride. It is through these local interests that people can be reached and the work done.

The feeling, the raw material and the machinery are all at hand. Part of the machinery is already in motion. Railroad officials were the first to see the value of protecting and beautifying the country through which their roads pass. Public school teachers are doing a great work in their Nature teaching. It now remains for that great network of organizations—the federated clubs, patriotic and religious societies—to do their share in making the land beautiful.

In club work village improvement committees in different parts of the state have a good record, but much desirable land could not be held under existing laws by any of the societies mentioned. To meet this condition Massachusetts incorporated six years ago that noble society of Public Reservations by which the trustees hold beautiful and historic places in any part of the state; and in Massachusetts the general opinion is, that public holdings of land, by giving an interest to all citizens, are of distinct benefit, and add to the value of private holdings. Is it possible for this organization to supply the motive power still needed?

The effect of Miss Dock's address was remarkable in the

general interest it excited, not only when delivered, but in press notices and in invitations for its repetition from teachers, schools and clubs in all sections of the state. At the meeting in Harrisburg it was evident that the more serious the proposition the closer was the attention. A resolution was unanimously adopted by the Federation declaring that, "in consideration of the importance of the preservation and cultivation of the forests of our state, both as a means of maintaining an adequate supply of water and of securing a proper distribution of rainfall, thereby increasing the state's productiveness and consequent wealth, the State Federation, through its clubs and its individual members, should use every effort to arouse interest in our forest conditions and resources with a view to an intelligent understanding of the value of forest preserves and the best means of protection and cultivation."

New York.

### Notes.

Dr. J. N. Rose, of the United States National Museum, has lately returned to Washington from a five months' botanical expedition through Mexico, bringing with him a collection of more than fifteen hundred species. Most of the collecting was done in the states of Durango, Zacatecas and Jalisco, and in a region which, it is said, has never before been visited by a botanist.

The decadence in training wall fruits has recently been the subject of considerable discussion in several numbers of the *Journal of Horticulture and Cottage Gardener*. The reasons given for the decline of this department of English gardening during the past twenty years are reduced labor, partly caused by the depression in agriculture and in everything pertaining to land; and to the larger outlay for society expenses, the garden being usually the first department of an establishment to feel the effect of economy. Besides, the increasing lavishness in table and house decorations make an excessive demand on labor, so that the vegetables and fruits are neglected and receive only hurried and careless attention. The garden walls which were once the pride of the gardener in their orderly training, and in the health and fruitfulness of the trees, now frequently have an air of neglect and unproductiveness.

The most brilliant plant in northern gardens, now that December has come and leaves have fallen or withered, is the native Black Alder (*Ilex verticillata*), which, this season, is unusually well covered with its bright red fruits that make a brilliant show in the landscape. Almost equally brilliant are the fruits of the Japanese *Berberis Thunbergii*, which still retains a few of its scarlet leaves. This Japanese Barberry has proved to be one of the best exotic shrubs which has been introduced into this country, where it appears to be fully appreciated and is now largely planted. No other shrub carries more brilliant fruit through the entire winter, and few shrubs make a braver showing in autumn dress. Some of the American Hawthorns, too, are still brilliant, although their leaves have fallen. The most conspicuous, perhaps, is the Washington Thorn (*Crataegus cordata*), which is still loaded with its small bright orange-red fruits. *Crataegus Crus-Galli*, with less brilliantly colored fruit, is beautiful, too, until the very end of winter, and the fruits of *Crataegus viridis* and *Crataegus Carrieri* still retain all their beauty of form and color.

The *Pacific Rural Press*, in a recent issue, describes and figures the Mammoth Blackberry, a hybrid between *Rubus ursinus*, the common wild Blackberry of California, and the Texas Early, a form of *Rubus villosus*, recently obtained by Judge J. H. Logan, of Santa Cruz, the originator of the Logan berry. The Mammoth, which is a cross between two plants which produce medium-sized fruit, curiously bears berries of immense size, fruits two and three-eighths of an inch in length being common. The canes of the Mammoth are large and thickly covered with small short spines; starting early in March, they grow thick and stout until about five feet high, and then, becoming pendulous or semiprostrate, grow from twenty-five to thirty feet more during the season; late in the autumn the tips of these shoots take root. Producing no adventitious root-buds, this variety cannot be propagated by root-cuttings, and the only way to multiply it is with stolons. The Mammoth begins to grow and flower early in the spring and ripens its fruit at Santa Cruz the last of May, or some weeks earlier than the Lawton. The flavor of the fruit is described as more acid than that of the Lawton, but when perfectly ripe is said to be sweet; when cooked or canned the flavor is identical with that of the fruit of the wild California

Blackberry, which is excellent, although, owing to its poor bearing qualities, it is rarely cultivated.

For Thanksgiving-day trade, last week, tempting arrays of fruits were made in the markets and stores. California grapes were offered in large variety and of excellent quality, and, handsome with their rich bloom, these looked as fresh and crisp as when taken from the vines several weeks ago. New York state grapes, of remarkable freshness for this season, were also displayed in variety, and included good Niagaras and Delawares. Lady-apples, some red bananas, strawberries from California, cocoanuts, pineapples, Italian and French chestnuts and cranberries were all in special demand. Other favorite fruits were Florida oranges and grape-fruits, choice varieties of pears, as Winter Seckel and Comice, and showy apples. During last week 37,633 barrels of the latter fruit were received in this city for the local trade, besides 18,861 barrels for export. Other receipts of fruits last week were two cargoes of cocoanuts from Colon and Trinidad, which comprised nearly 250,000 of these fruits, and four steamers brought 60,000 bunches of bananas from Jamaica and Central America. One cargo from Kingston, Jamaica, consisted of 10,613 barrels of oranges and 665 boxes, besides other shipments of oranges from the same island. There are now on the way from the Mediterranean to this port 6,200 barrels of Almeria grapes, 3,000 boxes of oranges and 60,700 boxes of lemons. Fruits are still coming from the Pacific coast, and twenty-one carloads were sold here last week, of which nineteen were grapes. Other western fruits received were Winter Nelis pears from Oregon, Easter Beurre and other late varieties of pears from California, a carload of new crop Navel oranges from the southern part of the same state, and attractive lemons of excellent quality.

"The Cherry in Delaware" is the title of Bulletin No. 35, issued by the Delaware College Agricultural Experiment Station. In a systematic treatment of the subject, Mr. G. Harold Powell, Horticulturist and Entomologist of the station, clearly explains the classification of this fruit; the practical considerations of soil, location, distance of trees; the propagating of varieties; pruning; cultivation; injurious fungi; insect enemies; climatic injuries; handling the crop and profits. The Cherry interests of Delaware, it is stated, are confined to dooryard and garden spots, and the product is disposed of in the local markets at prices that warrant an extension of the industry. The Cherry-tree thrives best in a warm, dry, loamy soil. The sour Cherry likes more moisture and is hardier. Soils too dry can often be improved by the addition of humus and by cultural aids. The land should be plowed early in spring and receive frequent cultivation until the first or middle of July, and then be seeded to a cover crop. Sour cherries can be grown commercially in all parts of the state, but the sweet Cherry should be confined to the rolling lands of New Castle County. The orchards should be placed on an elevation sloping to the north and the fruit-buds will thus be retarded in spring. Sweet Cherries should be planted thirty feet, and sour Cherry-trees sixteen to eighteen feet apart each way. The buds for the future orchard should be selected from trees of a uniformly heavy-bearing habit, as a promiscuous selection tends to make unlike trees. Sour Cherry-trees should be pruned similarly to the Peach; sweet Cherries should have three to five main arms. Brown rot is the most destructive fungous disease and can be controlled by spraying and by picking the fruit just before it is ripe. Black aphid and curculio are the worst insect enemies. Both are most destructive to the sweet varieties, though the curculio is sometimes serious in the sour kinds. Spraying controls black aphid, and jarring the latter pest. Sun-scald and bursting of the bark are not uncommon and are due to climatic influences. They are favored by nitrogenous fertilizers, late fall growth and exposure of trunk. Care in the selection of soil and in fertilizing, and a low-headed spreading form of tree reduce the danger. Geographical varieties are as yet undeveloped. The most profitable among sour Cherries are Montmorency and Early Richmond, and among sweet varieties, Black Tartarian, Roberts' Red Heart, Napoleon, Windsor and the new Dikeman, described on page 367 of this volume of GARDEN AND FOREST. A list of varieties suitable for home use is also given. It is important that the packages for market be small and neat. The purpose of the bulletin is to awaken an interest in the cultivation of this fruit, so that it may help supplement the present products of farms in localities where it can be successfully grown. This interesting pamphlet records a practical experience in the cultivation of Cherries in sections of country where it has for years been a profitable industry, and half-tone illustrations add to the value of the text.

Pogonia ophioglossioides, Fig. 61.....	485

## City Playgrounds.

THE importance of fresh air to the inhabitants of crowded city tenement districts certainly needs no demonstration; and there are now few thoughtful persons who do not realize the necessity of providing city children with abundant and convenient opportunity to play the outdoor games which belong to their age. The value of playgrounds for the general welfare and uplifting of urban populations is so well understood in Europe that every large European city is well supplied with small parks, squares and playgrounds. London men and boys can now stretch their limbs and harden their muscles in more than a thousand municipal cricket grounds and football fields, and on innumerable public tennis courts, hockey grounds and golf links. Other large English cities are following the example set by the capital; and in Paris, Berlin and Vienna the welfare of children is provided for as it never has been before. In this country there is little stent to the money spent in cramming the youthful mind with information which is not always particularly useful to the recipients in their later practical struggles with the world, but comparatively little is done by our municipalities to make children physically strong and healthy. Almost invariably the public school-houses in thickly-settled districts are destitute of open spaces about them, or these are limited to a few square feet of brick-paved yards usually too small to hold all the children of the school, to say nothing of affording them an opportunity for exercise. Small children and girls usually play in the streets, and the large boys, if they play their games at all, are forced to make excursions to distant parts of the city, or into open suburbs which every year become more remote. American cities are growing in population at the expense of the country, and unless this movement from the country to centres of population is checked, the men and, what is more important, the mothers of the men who are going to make American democracy a success or a failure, will be largely city bred. Something, to be sure, has been done to help the boys and girls of several American cities to secure health, strength and cheerfulness, but the movement for a better provision for their physical

welfare certainly has not kept pace with municipal development in some other directions.

In this city the small parks at Mulberry Bend and Corlear's Hook, in the very heart of what is said to be the most thickly populated region in America or Europe, show what can be accomplished in a short time, and how the health and character of the inhabitants of whole districts can be improved by knocking down a few buildings and covering the space which they had occupied with grass and trees, well-graded walks and comfortable benches. New York has legislative authority to spend a million dollars a year in buying land for small parks and playgrounds, and has recently acquired a number of squares for this purpose; and in a recent report of the Mayor's Advisory Committee on Small Parks, of which Mr. Abram S. Hewitt is chairman, the laying out of thirteen additional playgrounds is recommended.

Philadelphia, where a healthy public interest in the subject has been roused by the activity and zeal of the members of the City Parks Association, a body of men and women joined together for the purpose, has purchased since 1888 about one hundred and forty acres of land for small parks and playgrounds and now has two hundred and seventy acres of public grounds outside its large park system. As compared with either New York or Philadelphia Boston is badly equipped with playgrounds in her crowded districts. The city has spent great sums of money in developing an excellent park system, with large and small country parks connected by an admirable parkway; and in Franklin Field, which is still remote from the crowded parts of the city, it has a really noble country playground. During the past year several pieces of land have been purchased by the city for playgrounds but these are mostly in too remote outlying districts to be of real value to the present generation of boys and girls; and with the exception of two north end school-houses, for which a very inadequate playground has been recently bought, no provision is made for the outdoor recreation of school-children near their schools. No good opportunity is given to boys to play baseball, football or hockey anywhere in the city proper except on the Common or anywhere outside the city nearer than Franklin Park or Franklin Field, and the Common is so much used for other purposes that it cannot safely serve now as a playground any more than Madison Square in this city or Liberty Square in Philadelphia can be properly used for games of baseball. The Charlesbank, a narrow strip of land between Charles Street and the Charles River, with its well-equipped gymnasium for boys and girls, is an excellent playground for those who are satisfied with gymnastic exercises; and small boys and girls find an opportunity to play on Charlestown Heights and in the small north end marine park. In other parts of the city there is little space for the recreation of small children, and the story of the efforts of the Massachusetts Emergency and Hygienic Association to furnish places for the little children of Boston to play during the summer months, which is printed in another column, is, to say the least, pathetic.

Even in this city and in Philadelphia, where certainly more attention has been given to this subject than in the other American cities, the full meaning of what is needed in the way of urban recreation grounds has not always been fully understood, and there is evidently some confusion in the public mind with regard to a proper distinction between small parks and playgrounds. Mulberry Bend is a small city park or square laid out with broad walks, and lawns planted with trees and shrubs; it is an attractive and beautiful spot, and it has already had an elevating and healthy influence on the community. Mothers with sick children can find there fresh air, shade, and comfortable seats, and little boys and girls can run about with more freedom on the broad, smooth asphalted walks than they can in narrow crowded streets. Mulberry

Bend, however, is in no sense a playground; it does not contain even a sand garden, the crowning joy of little children in whom the digging instinct is always strongly developed; no manly games can be allowed for there is no room for them; and if the fences which surround the lawns were taken down, the beauty and value of the turf would be destroyed in a single day. Green grass, trees and flowers, with plenty of opportunity to sit and look at them, are needed in all crowded city districts. There cannot be too many such open places; they add to the beauty of cities and to the health and enjoyment of their inhabitants, and by increasing the value of adjacent real estate increase municipal income. Who can figure in dollars and cents the value of Union Square in this city, or place a money estimate on Boston Common? But parks, large and small, useful as they are, are not the only metropolitan outdoor equipment needed for the best development of a city population, and for the children at least real playgrounds are even more important. These should be of two classes: first, small open spaces, if possible adjacent to or near school-houses, where small children can play in safety such games as suit their age and in which sand gardens and a simple gymnastic apparatus can be properly established; and second, larger grounds of at least an acre in extent where boys can play rough games in freedom. In these larger playgrounds no elaborate and expensive laying out and subsequent costly maintenance are needed. The best possible playground is a piece of perfectly level ground with nothing whatever on it to interfere with the games. A good covering of turf would be desirable if it could be maintained on a city playground, but as this is impossible a surface of fine gravel or sifted coal ashes answers the purpose. A row of border trees gives dignity to the place, and affords shade to spectators who always gather to watch the sport of boys, and where trees do not interfere with the real purpose of the ground they can be advantageously used. In every city there should be a number of such open playgrounds used only for rough games and so situated that boys need not be obliged to make long journeys to distant suburbs in order to enjoy those outdoor sports which develop a manly spirit of healthy rivalry and are the best safeguards of youth against the temptations which come from idleness and the lack of opportunity to enjoy proper rational pastimes.

The necessity of municipal action in securing playgrounds is more urgent in this country now than it has ever been before. All American cities are growing rapidly in population and pushing far out over their suburbs. Private land within a reasonable distance of crowded centres of population, on which boys are often able to play, is fast being covered with buildings, and land suitable for playgrounds is everywhere increasing in value. The American city which sets the example of a really comprehensive plan for the healthy recreation of its boys and girls will have contributed something valuable to the civilization and material prosperity of the nation; and the Mayor who is fortunate enough to be in a position to carry out such a plan need not fear the ingratitude of his contemporaries and the forgetfulness or indifference of posterity.

Nothing has so discouraged persons who believe in the value of urban parks and realize the importance of their development along the lines of greatest utility as the action of the city of Philadelphia in allowing a corporation to establish and operate a trolley line into the heart of Fairmount Park. It seems incredible that ten Park Commissioners could have been found in Philadelphia so ignorant of their duties or so indifferent to their trust that a thing like this could have been possible, or that if the Park Commissioners had been captured by specious corporate arguments the intelligent and public-spirited people of the city could have permitted it. The most beautiful sylvan glades of the park are now noisy with the buzz of street cars. Trolley wires destroy every idea of country scenes; and the hideous iron bridge, built specially to carry this line

across the Schuylkill into the park, is a serious injury to the beautiful river drive which it crosses, and stands squarely in the middle of the fine picture which was obtained from Belmont, the commanding and most interesting point of view in the park. There are between four and five miles of trolley road in Fairmount Park, and the city has obtained nothing for the franchise which has been given to a company to destroy the greatest value of one of the largest and most beautiful of all urban parks.

It is not surprising after such an indication of public indifference to parks to find that, although more than half a million dollars is appropriated annually by the city for park maintenance and improvement, the roads in Fairmount Park are washed by gullies and often covered with weeds, that the turf is everywhere in a wretched condition, that the boundaries are unprotected by plantations, and that the trees are dying from neglect or are being ruined by overcrowding. Nor is it, perhaps, surprising that the artistic value of the wonderful Wissahickon drive, which might be made one of the most interesting park drives in the world, has been sadly marred by the hideous wooden road-houses built on city land, which appear at every turn, with no other screen before them than that afforded by the white-washed trunks of a few trees, or that its beauty is impaired by the tree-weeds which have sprung up along the banks of the river, and long neglected, are now ruining many of the noble Hemlocks for which the Wissahickon is famous, and shutting out from the drive charming bits of sylvan beauty and long reaches of sparkling waters.

If Fairmount Park and the Wissahickon are thus allowed to fall into decay, little is to be hoped from the management of Bartram's Garden on the Schuylkill, now one of the small city parks. A few years ago botanists and horticulturists in every land applauded the intelligence and public spirit of Philadelphia when it purchased this piece of ground, a spot of remarkable historical and scientific interest, for here was established the first botanic garden in the New World, and here was the house built by the hands of John Bartram and many of the trees which he had planted. The interest in this spot is more than local, for the name and achievements of Bartram are known and respected wherever botany is studied or trees are cultivated, and it is therefore more than a local misfortune that his garden is allowed to suffer from ignorant or indifferent management. The great Cypress, the glory of the garden, brought by Bartram 160 years ago from the lower county of Delaware in his saddle bag, and a vigorous tree a few years ago, is now barely alive, and many of the other trees planted by him show unmistakable signs of insufficient nourishment and excessive draining. Trees die sooner or later; but the lives of many of these might have been prolonged, the garden might have been spared the "clearing up" which has eradicated the herbaceous plants and many of the shrubs which added to its charm, and the old stone house might have been saved from the Japanese *Ampelopsis* which now hides its most picturesque side and seems as much out of place and as foreign to the scene as the yellow Japanese *Retinosporas* planted by the tomb of Washington at Mount Vernon.

#### Notes on Cultivated Conifers.—X.

**PICEA**, the Spruce, is a well-marked genus with flat or angular sessile leaves articulated on prominent bases, which become woody and are persistent on the stout branchlets, stalked terminal or axillary staminate flowers, and terminal, often elongated pendulous cones, with persistent, entire, or more or less notched scales always longer than their bracts. The Spruces are large, often gregarious forest trees with scaly or rarely furrowed bark, and pale, straight-grained, soft wood. The genus is widely and generally scattered over the northern hemisphere with about eighteen species, seven of them being inhabitants of the United States; it is well represented in Japan, and probably also in the interior of China. One of the species,

at least, is common over large areas in northern Asia, another grows only on the Himalayas, and three species occur in Europe. In *Picea* are found some of the most valuable timber-trees in the world, and in favorable climates all the species are handsome and popular park-trees.

The most commonly cultivated Spruce tree in the United States is a native of northern and central Europe, the so-called Norway Spruce, *Picea Picea* (the *Picea excelsa* of many authors). This is the great timber Spruce of European silviculturists, and in its native forests it is really a noble tree, sometimes 120 feet in height, and clothed to the ground, when not too crowded by its neighbors, with long gracefully curving branches furnished with elongated pendant branchlets closely covered with dark green lustrous leaves. Introduced into the United States early in the present century, the Norway Spruce has proved very hardy in all the northern and middle states, where it grows with vigor and rapidity for thirty or forty years, when generally beginning to fail at the top, it soon becomes thin and ragged in appearance, and healthy, vigorous Norway Spruces more than fifty years old are uncommon in this country. The introduction of this tree, as it has been planted here, in enormous numbers, must be considered a misfortune, for it is certainly not as well suited to our climate as some of the native species which nurserymen usually have neglected for this foreign tree, as, unfortunately, it can be raised very cheaply from seeds. Growing rapidly and making a good appearance while young, the Norway Spruce is popular, too, with those persons who want to produce some immediate effect with their trees, but do not realize that the vigorous young plants which they admire in the nursery are almost sure to become long before they have reached maturity such ugly ragged specimens as now disfigure nearly every public park and private estate in the northern part of this country.

A geographical variety of this European Spruce (var. *medioxima*) with shorter, thicker and more rigid leaves marked by small bands of stomata, and shorter cones with thin, delicate scales rounded at the apex, is described in vol. ix., page 273, of this journal, by Dr. Christ, who points out the relationship of this Swiss and northern alpine tree with the Siberian *Picea obovata*. This interesting form has never, I believe, been tried in our gardens, but *Picea obovata* and its variety *Schrenkiana* are now growing slowly in the Arnold Arboretum, where they are not particularly promising, although on the Altai Mountains, in northern Siberia, Manchuria and northern China, countries with climates not very unlike that of our northern states, these Spruces form vast continuous forests.

As might have been expected in the case of a tree which has been so much cultivated in nurseries, a large number of curious seminal forms of the Norway Spruce have appeared from time to time and can now often be seen in gardens. Beissner, in his *Handbuch der Nadelholzkunde*, describes fifty-six of these varieties; among them are some excellent dwarf plants like the variety *Gregoryana* and the variety *Clanbrasiliana*, which are often useful for the decoration of small gardens. The varieties *inversa* and *pendula* are interesting small trees with branches pendant to the stems, and the variety *monstrosa*, with long straggling snake-like branchlets covered with short bristling leaves and destitute of lateral branchlets, is one of the most curious and hideous of arborescent monstrosities. Several of the other described varieties are hardly distinguishable and others are merely juvenile forms which soon outgrow their peculiarities.

A much more valuable tree than the European Spruce for New England is the White Spruce (*Picea Canadensis*). This is the most boreal of the Spruces of eastern North America, where it is distributed from within the Arctic Circle to the northern borders of New England and New York, northern Michigan, Wisconsin and Minnesota, South Dakota and northern Montana. This tree, which sometimes attains a height of one hundred and fifty feet, may be distinguished by the strong fetid odor of the foliage,

the dark blue-green color of the leaves and the slender elongated cones, with thin rounded entire flexible scales. The White Spruce is a tree of the north and displays its greatest beauty only in cold countries, suffering in summer in the middle states and even in southern New England from the attacks of the red spider, which soon make the foliage thin and shabby. East of Cape Cod, however, it is the most beautiful of the Spruces which have been thoroughly tested here, dense in habit with persistent lower branches, and beautiful in color. Individuals vary considerably in the color of the foliage, however, one of the most distinct of these color forms being the tree with pale blue leaves (var. *cœrulea*) which is particularly attractive. Other forms with yellow leaves and with abbreviated or slightly pendulous or erect branches are cultivated in European collections. None of those which I have seen are particularly desirable or durable.

The Red Spruce (*Picea rubra*), an Appalachian species distributed from the valley of the lower St. Lawrence River to North Carolina, although little known in gardens and rarely planted, is a first-rate ornamental tree which might well be used in the northern and middle states instead of the Norway Spruce. The Red Spruce, which has long been confounded with the Black Spruce (*P. Mariana*, see GARDEN AND FOREST, vol. x., p. 62), is a tall slender tree frequently attaining the height of one hundred feet with thin branches and dense dark green foliage. The Red Spruce, which is the timber Spruce of New England, New York and the middle states, is a slow-growing tree in the forest, and it is not improbable that the oldest trees in New England belong to this species. I have had little opportunity to observe this tree in cultivation; the few planted trees, however, which I have seen are healthy and well furnished with branches and certainly have not grown very rapidly.

The Black Spruce is a smaller and more northern tree and an inhabitant of swamps and low wet ground. With the White Spruce it ranges to the Arctic Circle, and it is more generally spread over the northern states than the Red Spruce, which is confined to elevated regions except east of Cape Cod, where it reaches the coast, and it does not extend westward to the states bordering on the Great Lakes, where the Black Spruce is very abundant. The Black Spruce is a tree of rather open habit with blue-green foliage; in cultivation it soon becomes thin and shabby, and it is probably the least desirable of all the Spruces which have been fairly tested here as ornamental trees. Several varieties are described by nurserymen with the dwarf more or less compact habit or with the foliage marked with yellow or white, which are common seminal phenomena. None of these are particularly distinct or interesting enough to preserve.

Two Rocky Mountain Spruces discovered by Dr. C. C. Parry in 1861 and first raised by Dr. Asa Gray in the Harvard Botanic Garden, have proved hardy in the eastern states. The first of these trees, *Picea Engelmanni*, which is widely distributed from British Columbia to northern Arizona, is one of the most beautiful of the Spruces. It is a noble tree often a hundred and fifty feet in height with a tall stem covered with light cinnamon-red scaly bark, and pale blue acute soft leaves. This is the timber Spruce of the high slopes of the Rocky Mountains, where it forms great forests at elevations from eight thousand to eleven thousand feet above the sea-level. Here in New England *Picea Engelmanni* grows slowly, like most trees which have been transplanted from high altitudes to the sea-level, forming a handsome narrow and very compact pyramid with its lower branches resting on the ground. The largest trees have produced a few cones here. Unfortunately, *Picea Engelmanni* begins to grow very early in the spring and therefore it is frequently injured in western Europe by spring frosts, although in northern Russia it appears to be one of the hardiest and most valuable conifers.

*Picea Parryana* (the *Picea pungens* of most authors), the second Rocky Mountain species, the so-called Colorado

Blue Spruce, is a tree of more restricted range, being confined to Colorado, eastern Utah, and Wyoming, growing only along the banks of streams in small isolated groves at elevations between six and nine thousand feet. This species may be distinguished from Engelmann's Spruce by its pale, deeply furrowed bark, which is unusual in this genus, by its stouter glabrous branchlets and thicker rigid sharp-pointed leaves, bright blue on some plants and dull gray-green on others, and by its larger cones. As it appears in Colorado, *Picea Parryana* is a far less beautiful tree than *Picea Engelmanni*. The lower branches are soon overshadowed by those above them and then quickly die, and trees more than fifty feet high are usually thin and ragged in the tops. This Colorado Spruce has proved very hardy on the Atlantic seaboard, where it has been largely disseminated by nurserymen, and young plants are surprisingly vigorous and very handsome. The lower branches on the oldest specimens cultivated here, however, are already beginning to die, and there is every prospect that this Spruce will prove a failure as an ornamental tree. Among the seedlings raised from Dr. Parry's first seeds is a dwarf form which is still less than three feet in height and a handsome broad round-topped bush.

Neither of the Pacific coast *Piceas* has succeeded in the eastern states. Of these the Sitka, or Tidewater Spruce (*Picea Sitchensis*), is the largest of all Spruce-trees and one of the most majestic and beautiful of our conifers. The second Pacific Spruce (*Picea Breweriana*, see GARDEN AND FOREST, vol. iii., figs. 15, 16; vol. v., fig. 102) is remarkable in its pendant branches and long slender snake-like branchlets. Young plants of this tree, which is known only in a few isolated groves on the mountains of northern California and southern Oregon, have been successfully transplanted by Mr. A. J. Johnson into his nursery at Astoria, Oregon; and others may be seen in gardens in Portland. The efforts which have been made to raise Brewer's Spruce from seeds, however, in the eastern states and in Europe have not been successful, as the seedlings have an unfortunate habit of damping off as soon as they appear above the surface of the ground; and a few small grafted plants in the Arnold Arboretum are probably the only representatives of this interesting tree in the eastern states.

Japan is rich in species of *Picea* which, except in the extreme western and northern parts of Yezo, do not grow gregariously in great forests, as they often do in other parts of the world, but are scattered, usually singly, among the deciduous-leaved trees. The Japanese Spruces which have been the longest tried in our gardens are *Picea polita* and *Picea Ajanensis*. The former is a tree with stout rigid sharp-pointed yellow-green leaves, interesting in the fact that in our climate it begins to grow later in the spring than any of the other Spruces. This tree has been cultivated in the eastern states for twenty-five or thirty years and is very hardy in eastern Massachusetts, where there are a number of shapely specimens which have produced cones abundantly for a number of years. I should have considered this Spruce a most promising ornamental tree if I had not seen it in the forests of Japan. Perhaps it grows more thriftily in other parts of the empire, but on the Nikkō Mountains near Lake Chuzengi, which is the only place where I saw it, *Picea polita* was small, stunted, and miserable in appearance with thin tops and short ragged branches.

*Picea Ajanensis* is usually found in our gardens under the name of *Picea Alcockiana*, a tree with four-sided leaves which grows only on the mountains of central Hondo, where it is rather local, while *Picea Ajanensis* is one of the flat-leaved species and appears to be widely spread over north-eastern Asia, from Japan to Manchuria. I did not see this tree in Hondo, but in Yezo it is the common Spruce, forming forests in the western part of the island on low swampy ground not much raised above the surface of the ocean, and growing in the central districts usually singly among deciduous-leaved trees on low rocky

hills. This is also the common Spruce-tree of Saghalin and the Manchurian coast. In the eastern United States where there are cone-bearing plants of *Picea Ajanensis* twenty-five or thirty feet in height, it is hardy, fast-growing and very handsome, with well-developed lower branches, and numerous branchlets clothed with leaves which are dark green and lustrous on one surface and glaucous white on the other. In early spring this tree is very conspicuous from the bright red color of the young branchlets when they first emerge from the buds. So far as I have been able to observe the true *Picea Alcockiana*, which should, perhaps, be called *P. bicolor*, has not succeeded in the United States and I have seen only very small plants here. *Picea Glenhi*, the fourth Japanese Spruce, first discovered on Saghalin, reaches southern Yezo and is possibly only a geographical form of the Siberian *Picea obovata*. A large number of plants of this species has been raised in the Arnold Arboretum, but they are still too small to give any idea of the value of this tree in our climate.

The curious dwarf Spruce considered by Maximowicz as a variety of *Picea obovata* (var. *Japonica*) but usually cultivated under its first name, *Picea Maximowiczii*, is perfectly hardy in the neighborhood of Boston. It is a bushy plant (the largest specimen in Mr. Hunnewell's pinetum is now from five to six feet in height) with slender cinnamon-brown glabrous twigs clothed with remote needle-shaped dark green four-sided acute leaves spreading in all directions nearly at right angles to the branch. This plant was first raised from seeds distributed about thirty years ago from the Botanic Garden of St. Petersburg. Nothing appears to be known of it in a wild state, and it has been suggested that it is a monstrous or juvenile form of some other species. As a curiosity *Picea Maximowiczii* is worth a place in collections of conifers. The beautiful Himalayan Spruce-tree (*Picea Smithiana*), which is one of the largest of the genus, is widely scattered over the mountain ranges of northern India at elevations between six and eleven thousand feet above the sea-level, and is hardy in a young state, at least, in sheltered positions in the middle states. I have not seen large trees in this country.

*Picea orientalis* from the slopes of the Taurus and the Caucasus is one of the handsomest, hardiest and most valuable of the exotic conifers introduced into our gardens, where it has now been successfully grown for nearly fifty years. It is a large tree of dense narrow pyramidal habit with dark green lustrous rigid leaves which are so closely pressed against the branchlets that these appear more slender than those of other Spruce-trees. Beautiful specimens of the Oriental Spruce may be seen in the neighborhood of Philadelphia, in the old Parsons Nursery at Flushing, Long Island, and in Mr. Hunnewell's pinetum. So far as it is safe to form an opinion based on an experience of only fifty years it would appear wise to plant the Oriental Spruce much more frequently in this country than has been done.

The third European species, *Picea Omorika*, an inhabitant of the mountains of Servia, Bosnia and Montenegro, is interesting in its resemblance to the Pacific *Picea Sitchensis* and some species of north-western Asia in the character of its leaves, and in the fact that it was discovered only a few years ago. This Spruce, which is described as a large tree in its native forests, has proved hardy in the neighborhood of Boston, where there are now several plants five or six feet in height. Here it is attractive in its good habit and in the color of the leaves which are straight, flat, linear-oblong, obtuse and rounded at the apex, from one-half to three-quarters of an inch in length, green and lustrous on one surface and pale on the other.

Nature uses actual beauty only as a luxury; for occasional and sparing adornment, sometimes a little while in profusion, but never making it a lasting feature of any prominent objects.—*Halcyon Days*.

## New or Little-known Plants.

## Orchids in the South Mountain, Pennsylvania.

FOR several years the discovery of "high-toweringspikes of Purple Orchis," *Habenaria fimbriata*, had been an unrealized dream, but this year, late in June, unexpectedly

plant was twenty-eight inches in height, with a flower-spike three inches in diameter and seven inches in length. In the orange *Habenaria*, owing to the greater number of flowers, the lower portion of the spike is usually withered some time before the upper part has opened, but in this specimen of *H. fimbriata* almost every blossom was more or less expanded and quite unfaded when first gathered. Lifted above the mat of moss and grass in which it was growing, it was regal and almost startling as one suddenly came upon it the first time.

This *Habenaria* is rare in that locality, probably owing to washouts in recent years along many branches of the Creek, for other Orchids growing in meadows and protected places are abundant. My assistant told me he had seen but one other specimen, and I wish that careless collectors of wild flowers might have seen the way in which he took up and carried this plant. The photograph conveys an idea of the stately habit of the plant, but fails entirely (owing to the reduced scale—only one-third the natural size) to indicate the rich fullness of its foliage, and without color it is impossible to imagine the clear translucent tone of its feathery blossoms. Purple is such a violent-sounding term to use, and yet these delicate flowers are undeniably purple, of a very pure tone, with no red apparent.

The *Habenarias* bear transplanting very well, and nothing could be more beautiful in large grounds with a running brook than a grassy point set with purple Orchis and screened from the sun by overhanging *Nemopanthes*, white *Azaleas* and *Witch Hazels*.

The graceful, delicate little plant, *Pogonia ophioglossioides*, bears what Mr. Baldwin truly calls a harsh and irritating name; one of the names that has helped stifle a growing interest in many a flower lover, who with appreciation of delicate texture, exquisite color and form, has not yet mastered Greek roots. In the South Mountain the *Pogonia* is found in quantities in the latter part of June, but it is easy to miss them for their season of bloom is short. One week there is an expanse of grassy field, the next week it is starred with the lovely pink blossoms, and the following week one may look in vain for one.

*Pogonia ophioglossioides* is by no means always found associated with *Calopogon*, but the latter is invariably found with the *Pogonia*, and two stalks of *C. pulchellus*, to the left in the illustration on page 485, were allowed to remain in the sphagnum bed when the *Pogonias* and their concealing grasses were lifted from their swamp-meadow home, and carried sixty miles to be photographed.

The *Pogonia* is fibrous-rooted, with slender two-leaved stems usually the height of the surrounding marsh grass or seven or eight inches tall; but frequently specimens ten and twelve inches high and bearing two flowers are found. The pink color of this Orchid has been the subject of many vain attempts at description, and is to other pinks what the blue of *Fringed Gentian* is to other

blues, unforgettable but indescribable. It is a pure pink, not rose or flame tinted; of uniform tint in sepals and petals, excepting the bearded lip, which is white, with groups of epidermal cells scattered irregularly along the

Fig. 60.—*Habenaria fimbriata*.

I found three stalks growing close together on a shaded islet of the Conococheague, in the western border of the South Mountain, in Pennsylvania, and most reluctantly bore away the specimen illustrated on this page. This

veins, and the extreme delicacy of color is due to this contrasted petal.

Inquiry in several directions has so far failed to discover in this country the successful cultivation of these two associated bog Orchids, but Mr. Thomas Meehan informs me that the late Comte de Paris, an enthusiastic Orchid collector, had standing orders in this country for native plants, and reported entire success in naturalizing both *Pogonia* and *Calopogon*. It would be interesting to know what treatment they received, that we might in time have more meadows filled with this all too short-seasoned flower.

### London Letter.

**A NEW DENDROBIUM.**—Over two thousand newly imported plants of a supposed new species of *Dendrobium* were sold by auction to-day at the instance of Messrs. F. Sander & Co. The catalogue description states that the flowers are large and produced in profusion. The labellum is broad and of a deep crimson color, the sepals and petals thick and overlapping as in the *Moth Orchid*, and of all shades of color. The bulbs literally bristle with old flower-spikes. This is a plant for the florist, and it will become popular, as it is a winter bloomer. The Bismarck islanders told the collector that the flowering season was December and January, which he verified from Mr. Ohlsen, the missionary. The different and quite new habitat of this species accounts for its winter flowering, and although it may bear some resemblance to the magnificent *Dendrobium Phalaenopsis*, it is totally distinct from that plant. It may prove the winter-flowering companion of that species. There is a great variation among these plants. The bulbs differ so greatly that possibly more than one species is present. The collector wrote that he found the plants growing among low shrubs in almost pure sand and débris, and that the flowers were exquisite and of all shades of color, covering the shrubs with myriads of butterfly-like blooms.

**LEEA AMABILIS SPLENDENS.**—This is an improvement upon the type, which was introduced from Borneo fifteen years ago by Messrs. Veitch & Sons, when it received much attention because of the rich color and elegance of its foliage, and was appropriately described as resembling a shrubby *Cissus discolor*. It failed, however, to become an established favorite, chiefly on account of its leaves losing their variegation when the plants grew to any size. I am told that in the tropics it grows to a large size and is then wholly green. I lately saw in the nursery of Mr. Bause some plants of the variety above named, which he says have so far retained the rich dark velvety green and silvery feather-like variegation when grown to a good size, and, as the band of white extends, not only along the midrib, but also along the main lateral veins, the beauty of the plant is of a high order.

**THE PAMPAS GRASS AND ITS ALLIES.**—This is the subject of an interesting paper by Dr. O. Stapf, of Kew, the first part of which is published this week in *The Gardeners' Chronicle*. Although fourteen species of *Gynerium* have been described, only two or three of them have ever found a place among garden plants, and only one, namely, *G. argenteum*, the Pampas Grass, has become really popular. A second species, *G. saccharoides*, a native of South America, is grown at Kew and in a few other gardens. Its large, elegant plumes are extensively imported and sold for decorative purposes under the name of Uva Grass. This species differs markedly from the Pampas Grass in its tall Bamboo-like culms, which are from twenty to thirty feet high, with leaves as much as twelve feet long. A parallel case was that of the Bamboo-like *Arundo donax* and the tufted *A. conspicua*, until Dr. Stapf discovered that the latter is not an *Arundo*, but a distinct genus, which I believe he has named *Cortaderia*.

**ACNIDA AUSTRALIS.**—Seeds of this plant have recently been

received at Kew, accompanied by particulars of its growth and habit, as observed in the peninsular portion of the state of Florida, where it would appear to grow to an extraordinary size in a few months. It is described as an annual, making most of its growth from May to August, and ripening its fruit in September or October. In rich boggy soil its stem sometimes grows to a circumference of more than three feet, with a height of twenty-five feet and branches capable of supporting the weight of a heavy man. Specimens have been described as "thirty feet high and as big as a barrel." The trunk is described as dark crimson in color, the leaves of a shining rich green and the flower-spike pyramidal. For an annual this is a phenomenal plant. Its behavior at Kew will be watched with interest. The genus is a near ally to *Amarantus*, and there are four or five species, all American.

**WINTER-FLOWERING BEGONIAS.**—Three new hybrids raised from *Begonia Socotrana* and tuberous varieties have lately been distributed by the raisers, Messrs. J. Veitch & Sons. They are now nicely in flower in the Begonia-house at Kew, and are remarkable for their sturdiness of stem and closer approximation to the tuberous-rooted sorts than any other of the *Socotrana* hybrids. The flowers are large and full, fleshy, and the colors are rich. They are: *Ensign*, which has semidouble flowers over two inches in diameter borne on erect peduncles; their color is rich rose-pink; *Mrs. Heal* is dwarfier, the peduncles are numerous, erect and long enough to raise the flowers well above the foliage; they are three inches in diameter and colored deep carmine; *Myra* has long, slightly arching peduncles, and the flowers are of a bright rose-carmine color. As is the case with all the *Socotrana* hybrids, the flowers of these new ones are persistent. *B. Socotrana* is now flowering freely in the stoves at Kew.

**CANNELL'S ZONAL PELARGONIUMS.**—Mr. Cannell's exhibit of cut blooms of Zonal Pelargoniums was perhaps the most striking feature, outside the Chrysanthemums, at the Aquarium exhibition last week. No one has done so much to improve and popularize these plants as he, and no one appears to enter into competition with him as a grower and exhibitor of them. A table stretching across the exhibition hall was entirely filled with large pyramidal, bouquet-like bunches of flowers of exceptionally large size and lustrous colors, an altogether marvelous production for mid-November in this climate. I noted the following as the most attractive in size, form and color of bloom: *Niagara*, pure white; *Red Eagle*, scarlet, white eye; *Gertrude Pearson*, pink, white eye; *Miss E. Wilson*, pale salmon-pink, red eye; *Countess de Morella*, scarlet, large white eye; *Miss P. Routh*, salmon-pink, very large; *A. Tennyson*, scarlet; *Duchess of Marlborough*, pale salmon, darker centre, very large. I believe I have already written you some particulars of Mr. Cannell's cultural methods for these plants. The essential conditions are liberal cultivation in pots out-of-doors during summer, the removal of all flower-buds until October, housing the plants in a light greenhouse close to the roof-glass, and keeping the atmosphere dry by means of thin hot-water pipes fixed among the plants or directly over them. The plants are encouraged to make a few shoots and the flower-heads are removed as soon as the flowers are over. The difference between the Zonal Pelargonium as seen in the ordinary way and as grown by Mr. Cannell is as great as that between a half-starved Chrysanthemum and the specimens one sees at exhibitions.

### Seasonable Work.

WE have had some wintry weather quite early this year, there having been two moderately heavy snowfalls before Thanksgiving Day, November 25th, and one or two quite severe frosts. Until November 19th, when we had our first snowfall, the season was unusually open here, and Pansies, hardy Chrysanthemums, Geraniums, Verbenas, etc., were still blooming in the open. As a rule, we can carry on outdoor

Fig. 1. — Begonia, lily, and fern. — See page 473.

operations here until Christmas with a few breaks, and although the appearances are wintery at present, we may still have not a few mild days before winter sets in steadily.

Perennial borders have recently been gone over, all dead tops cut down, weeds hoed up and raked off, and a liberal coating of well-rotted manure spread over the whole. Perennials to do their best must be liberally fed. Too often they are starved. The contrast between a bed heavily mulched in late fall and one scantily supplied with manure is striking. We leave the manure on the surface to act as a mulch during the following summer, scratching it over and breaking up the lumps with an iron rake. Doubtfully hardy plants, such as *Helianthus multiflorus* plenus, *Anemone Japonica*, *Tritomas*, *Montbretias*, *Heuchera sanguinea*, etc., are protected by a few shovelfuls of half-decayed leaves. Beds containing bulbs are covered with a few inches of leaves, over which pieces of boards are laid to keep the leaves from blowing about. It is quite a common practice to see Tulip and Hyacinth beds with a heavy coating of rotted manure as protection. A lighter material is preferable, as it takes some days for the frost to leave the manure when the season breaks. The bulbs themselves are perfectly hardy; the covering is given more to keep the frost from lifting the bulbs out of the beds than as protection. Flower-beds have recently been manured and dug, and present a neat appearance for the winter. No more of this work should be postponed until spring than is necessary.

Cold frames will now require to be secured from severe frost. We pack a few inches of dry leaves about the sides of ours. By doing this and using mats and shutters we are able to keep out the most severe frosts. After the ground is frozen hard in frames containing Pansies, Polyanthus, Wallflower, etc., and seedling perennials, we pack dry leaves over the plants, airing them on all mild days and removing the leaves on the first approach of spring. Stock plants of Chrysanthemums keep well if treated in this way. Lettuce grown in frames requires care in ventilation and watering at this season, or many of the plants will rot off. The surface soil will need scratching over occasionally, particularly if any green slime appears.

Violets are doing specially well this season, less disease being apparent than for several years. Marie Louise is still much the best sort, producing more flowers than any other kind. The color is much darker than that of Lady Hume Campbell. The latter is easier to grow and is a fine sort for those who cannot succeed with Marie Louise; it requires artificial heat in winter and is of little use in cold frames. The Farquhar gives a few fine flowers, but is not so robust a grower as Marie Louise; if it is well grown no other Violet can compare with it. Princess of Wales promises to be an excellent single Violet, much superior to California and Luxonne. Once a week Violets should be looked over, and decaying foliage, runners, etc., removed. If some runners have not been put in for next year's stock it is not yet too late to start a few in boxes; these should be kept over winter in a frame. Plants raised in the past two seasons in this way have been much superior to spring-rooted ones.

Compost heaps require attention at this season. We usually prepare ours early in December. It is hardly possible to arrange for too much good compost. For potting material sods of good fibrous loam are indispensable. We place a layer of well-rotted manure between each double layer of sods; a stack prepared now should not be used before next fall. Special compost heaps are required for Roses, Carnations, Chrysanthemums and Violets. I have seen good flowers of all these plants grown from the same compost, but, as a rule, growers prefer to make some distinction. Roses thrive best in a heavy retentive loam of a clayey nature, and are not at all happy when planted in a sandy compost which Carnations rather seem to like, but which Chrysanthemums would not take kindly to. All compost heaps require plenty of manure of the best quality. Leaf-soil is most useful in compost; three years are required for leaves to rot down sufficiently to make the best leaf-mold. If they can be turned over once a year they will decay more quickly. They should never be stacked near trees which will soon fill them with a mass of fibrous roots. In collecting leaves pine-needles should always be excluded, and all sticks and twigs be thrown aside.

Gooseberries and Currants have recently been pruned and well mulched with rotted manure. Some of the strongest prunings of each kind are saved and heeled in to give a succession of stout young bushes each year. The pruning of Pears, Apples and Grapevines will be concluded as weather permits. All prunings are raked up and burned, after which a liberal dressing of manure is given. Strawberries we cover

with leaves after the ground becomes frozen hard and throw some Pea brush over the top to keep the leaves from scattering.

Where Celery is wintered in the open it should now be well protected with leaves, straw or seaweed. It is keeping well this year with us. Golden Self-blanching and White Plume provide a supply until Christmas, after which we rely chiefly on Boston Market and Giant Pascal. Any vacant patches to be used for vegetables may be manured and dug while the weather permits. This will materially lessen the strain in spring, when so many operations are pressing at one time.

Taunton, Mass.

William N. Craig.

### The Pink Color in Chrysanthemums.

THE economic importance of Chrysanthemum-growing (which in this state is estimated to involve more capital than Peach cultivation) justifies the attention paid to this subject by the Cornell Experiment Station. Chrysanthemums are not yet quoted in market reports by names of varieties as Roses sometimes are, but the prices are usually given for the three prominent colors—white, yellow and pink. The various shades of pink seem to be exceedingly unstable. One of the popular commercial varieties is Fred Walz, which I have frequently seen in three or more easily distinguishable shades, although the plants seemed to be grown under very similar conditions. This variety being somewhat stiff and formal in outline, is easily ruined for artistic effect by unevenness of color. The mere fact that the pure pink of Mr. F. Schuyler Mathews's color-chart has not yet been attained in chrysanthemums is not so serious in itself, because that is only one particular shade. There seems to be an entire series of colors whose value is determined far more by the skill of the cultivator than by the variety. Amaranth, crimson, rosy pink, crimson-pink, light pink and blush-white are some of the names of trade catalogues which represent a gradation from the deepest shade of the series down to pure white, and it seems probable that any of these shades may in some cases be obtained from a single variety. Not all varieties, of course, are so highly susceptible as this, but frequently the difference is enough to make the flowers unsalable. The control of color, therefore, becomes a problem of great practical interest.

The problem is doubtless a complicated one. There seem to be at least five factors concerned, any one of which may change a pink to a white. The choice of buds is said to be sufficient in some cases. J. H. Woodford, one of Mr. Spaulding's novelties, is advertised as shell-pink from terminal, and pure white from crown-buds. Overpropagation is generally thought to weaken color. Temperature and ventilation (the two factors can hardly be separated in greenhouse practice) are advertised to produce three distinct and desirable shades in Mrs. Colonel Goodman. Mere position (in pots, beds or benches) should not in itself make a difference, but in practice it does. The effect of shade is variously stated. And most complicated of all, the food factor is known to influence color, but just how is a mystery.

Thirty-one varieties advertised as having various shades of pink were grown here under the same conditions. Fourteen gave white flowers with only a trace of pink at most in a few cases. Three others had much less color than their descriptions imply. I cannot explain such a condition. The general health of the plants was excellent. The four flowers on each plant averaged about six inches in diameter, and all the other details were entirely satisfactory.

Last year I noticed in another place some white varieties which showed pink. Among them were such important sorts as Our Mutual Friend and Marie Valteau, the latter, however, being less frequently described as pure white. The food being much richer than our own, especially in nitrogenous matter, I suspected that an extra supply of nitrogen might have called out the pink color which we had never observed in these white varieties. Mr. E. G. Hill warns his customers not to use nitrate of soda in the cultivation of certain light pink varieties, as it produces a deeper and unpleasant shade.

It was convenient to single out only two of the supposed factors this year, and the experiment has turned out contrary to my expectations. The extra amount of nitrogen did not deepen the color, but the flowers proved very sensitive to shade. Shade is said by some to deepen the color, but the reverse was true in this case. The difference was perceptible at a glance in the case of Mrs. Perrin, Madame Felix Perrin, Marie Valteau, Helen Bloodgood and Iora, and in a lesser degree with William Simpson and Maud Dean. This difference would not prevent the sale of Iora, which is usually uniform in color, whatever the shade may be. The varieties Mrs. Perrin

and Madame Felix Perrin, however, lost their characteristic, sparkling, rosy color, and were not of a salable character. Some of these varieties were shaded from the time the buds were the size of marbles until they came into full flower. Others had already burst their buds and were out an inch or more before the glass overhead was whitewashed. I know nothing about shading Chrysanthemums during the purely vegetative phase of their life. It seems clear, however, that during the reproductive phase the forming flowers are weakened in color by shading. There was only one contradictory plant among twenty-five. It is a common complaint among florists that the pink color stays only a few days after the flower opens, and perhaps sunlight and shade cannot then arrest the fading. The results with the nitrogen factor were not conclusive. At any rate, we did not force any pink into such white varieties as Lenawee and Our Mutual Friend.

One of the most popular of all Chrysanthemums is the white variety Ivory. It is included by many dealers in their list of twelve best varieties for commercial purposes. It is used for cut flowers and pot-plants, and still figures among the winners in the exhibitions. Naturally pink sports of it are eagerly sought after. Miss Agnes L. Dalskov (commonly called Pink Ivory) has been much praised elsewhere. With us it had barely a trace of color last year, and none in 1897.

Ithaca, N. Y.

### City Playgrounds.

To the Editor of GARDEN AND FOREST:

Sir,—The Massachusetts Emergency and Hygienic Association has led the way in this country in efforts to provide playgrounds for the summer use of children, and has now under its charge in Boston eleven yards, mostly belonging to schools, at which, during the summer of 1896, there was an average attendance of 1,804 children a day. These yards, of course, are only available during vacations. The valuable Charlesbank gymnasium accommodates a large neighborhood, and I am told that the average attendance there in the summer months is above a thousand a day; but there are many sections of the city too distant for the residents to avail themselves of the Charlesbank, and to them the great park systems are wholly inaccessible, so that these sections are in sore need of some municipal provision for spacious recreation-grounds. There is also an Emergency Playroom at Morgan Chapel, Shawmut Avenue, and the Episcopal Mission has provided seven rooms, where at certain hours children can play under proper supervision. There are vacation schools connected with Denison House, and the Lincoln House Settlement is doing admirable work in providing recreation for the poor of the South End, and, no doubt, there are other private provisions for their needs, but a great deal remains for the municipality to organize and pay for.

It may be of interest to your readers to know just what is being done by the Emergency and Hygienic Association in the yards they manage so admirably, and, therefore, I subjoin an account of some of them which I had the pleasure of visiting last summer with one of their public-spirited directors.

I was taken first to South Boston, to a sort of human chicken-coop on a three-cornered piece of land between two streets, left unoccupied when the Ellis Memorial was built. This space the trustees of the Memorial were glad to put at the service of the Association, and the ground was at first enclosed with a board fence, and later with slats to admit the air more fully, and shaded with a canvas awning. This awning I found in a very dilapidated condition at the end of the summer, it having been willfully torn by mischievous boys of the neighborhood, who at first gave a great deal of trouble to the managers by forcing an entrance and terrifying the children. The intrepidity of the matrons in charge of the ground, helped by the police, put the hoodlums to flight, and the younger children are no longer molested. The doors of all the yards, however, have to be kept locked to prevent the intrusion of the unruly element, always ready to make a disturbance, and only the younger children are admitted at the proper hours of recreation. There was nothing but a dirt floor in this poor and small, but much-valued enclosure; at one end were sand piles for the smallest children, in which they played contentedly with shovels and pails. There are superintendents called matrons in all the yards, whose business it is to keep order, to teach kindergarten games and occupations to the children, to take charge of and distribute the playthings and books which are provided, to settle disputes, and to keep out intruders. These young women, mostly school-teachers who desire to supple-

ment their small salaries by work in summer, take great interest in the little ones, know their names and characteristics, and are most kind and cordial in their treatment of them. It is interesting to note that though these teachers often begin the playground work when they are weary and worn with school-teaching, they grow brown and healthy in this daily occupation in the open air, even amid such poor surroundings. Two or three times a week, and sometimes daily, the yards are visited by members of the committee, who are a court of final appeal in case of difficulty.

From this playground we passed on to a more pleasant one at the Mather School, in South Boston, which is shaded in the morning by a few street-trees and by the high buildings about it. We had found about eighty children enjoying themselves in the dreary little pen at West Second Street, but here there were, or had been during the morning, nearly two hundred, who disported themselves upon the flagged pavement outside the schoolhouse enclosed by a high iron fence. Here were also sand pens and toys, and the boys and girls proudly exhibited the work they had done with cardboard and worsteds, or the little drawings they had made. Sometimes a baby in a carriage was wheeled and attended by an older child. At stated hours plays for the little ones were conducted by the matrons; among these the flag drill was particularly enjoyed. It was interesting to note the pleased expression on the wretched, depraved faces of men of the lowest description, who paused to look through the fence when the children were in a ring playing some of the pretty kindergarten games, and one realized that the playground was a civilizing influence, not only for the children, but for the adult neighbors who looked on.

Another schoolyard in Shawmut Avenue, opposite Lincoln House, was thronged at a later hour with frolicsome happy children, and in the lower part of the schoolhouse some of the girls gathered to paint flowers from nature. While I was there flowers, sent in great baskets from the Flower Mission, were distributed among the children, to their evident joy. Several newsboys dropped in for a spare twenty minutes to enjoy a game of checkers, and weary mothers came to leave their little ones in safe-keeping. Shawmut Avenue is a dirty street, and the dust blew about in clouds, but the boys and girls swept the yard frequently, and so kept it orderly. One longed for a tree or a corner of green shrubbery or a bit of grass. The visit later on to the Charlesbank Gymnasium was restful, and it was easy to realize what it must mean to the denizens of crowded tenement-houses to have such a resort, where shrubs and trees flourish, and there is a stretch of turf to roll upon.

The Earl of Meath has said it is better for a city to have a hundred parks of one acre than one park of a hundred acres. Frequent open spaces, with plants and grass in the corners, should be scattered for the use of children all through the great cities with their crowding houses, hard pavements and noisy streets, which until lately have been the only place where the young could amuse themselves. It is pathetic to see the great enjoyment which not only the children, but the mothers, take even in the least attractive of the yards, and the refining influence of the kind and sympathetic treatment which they receive is evident both upon the children and their parents. Many of the boys are so unused to decent treatment that when they first come they are in constant dread of a blow when the matrons approach them, but after a time they become respectful and helpful, and a book to read often tames the most obstreperous.

All that the directors ask is that the city shall furnish the yards with shade-trees, of which they are sorely in need. Even the broad stretch of greensward at the Charlesbank is unavailable on hot summer days, because it is absolutely unshaded. It seems a mistake to sacrifice the comfort of the children to a landscape-design which could hardly be fatally marred by one or two trees to afford a refuge from the burning summer sun.

But the city should do more than grant this simple request; it might clear away rubbishy old buildings and give open spaces for the use of children in every quarter of the city, as the authorities are doing in London. The Charlesbank, which we owe to the Park Commissioners of Boston, was the first free open-air gymnasium in the world, and this, under the superintendence of the Massachusetts Emergency and Hygienic Association, has already in three years added noticeably to the public health. Children with tendencies to curvature of the spine, with stiffness of the joints and general ill-health have had exercises prescribed for them by the careful superintendents, and these defects have been remedied. The matrons report the growing activity and vigor of the girls, 300 of whom

are now willing to practice gymnastics, which but few would attempt in the beginning. Nearly 3,000 towels, used in the girls' bathrooms alone, show how the once "unwashed" are learning to appreciate the free baths provided for them after exercise.

Any one who would visit the playgrounds which the Association has taken such generous care of for ten years, would feel with me that it is the most touching and interesting of charities, and one that cannot be too generously aided in its good work. A contribution of one dollar is sufficient to give one child for a summer the privileges of the playgrounds and valuable instruction in good citizenship. The matrons, of course, have to be paid, and there are certain incidental expenditures for toys and implements, though most of these are free gifts, as is the sand, ten heaps of which have been distributed for ten years by one firm. The public spirit of citizens has been generous, but an enterprise such as this, now so well started, with its course so clearly indicated, should not be left to charity alone, but be made one of the duties of the municipality.

Hingham, Mass.

Mary C. Robbins.

### Notes.

Professor James Troop, Horticulturist of Purdue University, was recently appointed State Entomologist by the Governor of Indiana.

During last week 1,003,900 cocoanuts reached this port on four steamers, from San Blas, San Andreas, Kingston and Port Antonio.

In the second number of *The Plant World* there is an account of Amos Eaton, one of the Nestors of American botany, accompanied by a full-page portrait.

Notwithstanding heavy rains in California, which interfered with the work of drying, the raisin product of that state for this year is estimated at 75,000,000 pounds, according to *The Fruit Trade Journal* of this city.

From three-year-old Peach orchards in the Ozark region, operated by the McNair Brothers this season, an abundant crop, of excellent quality, was produced. Eleven days were required for gathering and shipping, and the selected fruit was forwarded to eastern markets in refrigerator cars. The net returns amounted to \$165 an acre.

In the Revue of the Horticultural and Botanical Society of the Mouths of the Rhone, published in Marseilles, Monsieur Naudin has recently published notes on the fruiting at the Villa Thurer of *Araucaria Bidwillii*, *Jubæa spectabilis* and *Cocos australis*, a fact which will be of interest to gardeners in the warmer parts of the world.

Monsieur André in a recent issue of the *Revue Horticole* describes the new system adopted in Berlin for watering street trees by means of a number of small pits dug at some distance from their trunks and filled with perforated vertical drainpipes. The pits are covered with movable covers, and when it is desirable to water the trees these are removed and the pits filled with water, which enters the vertical drainpipes through the holes in their sides and gradually finds its way down to the roots of the trees. This system has been found very economical because none of the water is wasted, and as it reaches directly the ends of growing roots it is not necessary to water the trees frequently.

Mr. C. C. Andrews, Chief Fire Warden in Minnesota, in his preliminary report for 1897, regarding forest and prairie fires in that state, says the season of possible danger of forest and prairie fires lasted this year longer than usual, and a few fires occurred after the middle of November. The recent snowfall, though light, extended over most of the state, and probably no further damage need be apprehended this year. Dry weather prevailed over an extensive forest area about three weeks in April and May, and again in September and October. A number of fires occurred and a good proportion of them were extinguished or controlled by fire wardens and citizens who assisted them, so that no fire proved of very serious magnitude. Probably the total damage by forest fires in Minnesota this year will not exceed \$14,000. This is an improvement over last year, and considering that the standing timber in the state, at a low valuation, is worth \$100,000,000, the amount of damage is small. The principal work done under the fire-warden law is that of prevention. At a low figure the standing value of the Pine that will be cut in Minnesota this winter is \$5,000,000. When sawed into lumber at the mills its value will have increased to \$10,000,000, of which increase eighty

per cent, or \$4,000,000, represents labor. These figures only indicate in part the importance of the forest resources of the state.

The value of *Begonia Gloire de Lorraine*, as this admirable plant becomes better known in this country, is clearly demonstrated. It is a hybrid raised by Lemoine, of Nancy, in 1891, and is one of the most valuable of the long list of hybrids with which he has enriched gardens, and was obtained by crossing the winter-blooming tuberous-rooted *Begonia Socotrana* with *B. Dregei*. The hybrid, curiously enough, however, is not tuberous-rooted, but produces from the base of the stem numerous shoots which insure its rapid multiplication. This *Begonia*, with its neat habit and rather small clear green leaves, is covered from November to May with bright pink flowers, and is a delightful object with which to enliven the conservatory in winter or for table decoration. A flowering plant was figured in the fifth volume of *GARDEN AND FOREST* (page 244, fig. 48), and this *Begonia* was also described a year ago by our London correspondent (vol. ix., page 494), who speaks of it as the most popular *Begonia* in England. Although the flowers are considerably smaller than those of *B. Socotrana* and the foliage is less bold and striking, it will probably become a more popular plant than that species, as it is rather easier to manage, the flowers are numerous even on plants a few inches high, and the flowering season is much longer. In every respect this is one of the best winter-blooming plants of recent introduction.

The final importations of *Almeria* grapes for this year, received last week, showed no improvement in condition over those sold earlier in the season, many being unsound. A few barrels of choice-quality fruit in good condition reached the extreme price of \$15.00 a barrel at wholesale. The season for shipping New York state grapes has also just closed. From the grape section about Lake Erie alone 6,000 carloads of this fruit were forwarded. Last week marked the last arrivals of California grapes, when five carloads were sold here. The season for so-called deciduous fruits from the Pacific coast is now ended, and that of *Citrus* fruits is fairly begun. These oranges and lemons are, however, unduly hurried into market, being inferior in size and color. The orange crop of Florida for this season is estimated at 275,000 boxes. Last year's crop amounted to 160,000 boxes, and that of 1895, after the freeze, to 65,000 boxes. Four-fifths of this year's crop has already been sold by the growers, the fruit commanding \$2.00 to \$2.25 a box on the trees. The cost of wrapping, boxing, transportation, commissions, etc., must be added to these figures, and choice Florida oranges command from \$4.50 to \$5.50 a box from retail buyers in this city. Mandarins from the same state cost \$6.00 a box at wholesale, Tangerines, \$7.00 to \$10.00, and grape-fruit \$5.50 to \$6.00 a box. Among fruits recently exported were 100 boxes of Navel oranges, from California, shipped to England for the Christmas trade, a carload of pears from Oregon, and 100 boxes of California apples, to Hamburg.

Mr. William Hamilton, who, a century ago, lived at Woodlands, on the Schuylkill River, in what is now West Philadelphia, was interested in the cultivation of trees. Many exotic species were first planted in the New World in his garden, which in his time was the most famous establishment of the kind in America. Among other trees, he introduced the Lombardy Poplar and the Norway Maple into this country, and Pursh and other famous men were in his employ. Woodlands was long ago converted into a cemetery, and many of Hamilton's trees have thus been spared. The most conspicuous and interesting of these now are four plants of the Caucasian *Zelkova crenata*, probably the largest specimens of this interesting tree in America. They are comparatively low bushy trees, with short trunks about four feet in diameter, covered with smooth gray bark like that of the Beech, the small, crowded, erect branches forming dense oblong heads, which in winter, when the trees are bare of leaves, are extremely picturesque and interesting. *Zelkova*, which belongs to the Elm family and is related to *Planera*, of our southern states, consists of two species, one, the type of the genus, *Zelkova crenata*, being found only in the Caucasus and the adjacent regions, while the other species, *Zelkova Keaki*, is confined to Japan, where it is a large and exceedingly valuable timber-tree (see *GARDEN AND FOREST*, vol. vi., page 323, fig. 49). Introduced into the United States several years ago, this Japanese *Zelkova* promises to become here a large and handsome tree. The Caucasian species is less hardy, and, so far as we have observed, is only well represented in the United States by these four trees at Woodlands.

Park-making.

THOSE who make public parks are apt to attempt too much and to injure not only the beauty, but the practical value of their creations by loading them with unnecessary and costly details. From the time when landscape-gardening was first practiced as a fine art to the present day, park-makers have been ambitious to change the face of Nature—to dig lakes where lakes did not exist and to fill up lakes where they did exist, to cut down natural hills and to raise artificial ones, to plant in one place and to clear in another, and generally to spend money in construction entirely out of proportion to the value of the results obtained.

The best art is simple in its expression, and the highest form of art in gardening is perhaps that which, taking advantage of such natural conditions as it finds, makes the best of them with the smallest expenditure of labor and money. Simplicity of design means not only economy of construction, but, what is of even more importance, economy of maintenance. The importance of making it possible to keep a great park in good condition without excessive annual expenditures for maintenance is a simple business proposition which would not seem to require much demonstration. Yet park-makers, with their unnecessary walks and drives, with their expensive buildings which are always getting out of repair; their ponds, in which there is rarely water enough to keep them fresh; their brooks, which are frequently dry; their elaborate planting schemes often ill-suited to the positions where they are wanted, make parks expensive to construct and impossible to maintain in good condition, especially in this country, where the cost of labor is heavy and there is difficulty in obtaining under existing municipal methods skilled and faithful gardeners to keep anything like an elaborate garden in good condition. The most superficial examination of any of our large urban parks will show that wherever elaborate construction and planting have been attempted they have failed from subsequent neglect to produce the effects expected from them, and that broad, quiet, pastoral and sylvan features are the only permanent and really valuable ones we can hope to attain in our great city parks.

It is needless, perhaps, to repeat what has been said so often in the columns of this journal, that, in our judgment, the greatest value and only justification of great urban parks exist in the fact that they can bring the country into the city and give to people who are obliged to pass their lives in cities the opportunity to enjoy the refreshment of mind and body which can only be found in communion with Nature and the contemplation of beautiful natural objects harmoniously arranged. Parks have other and very important uses, but this is their highest claim to recognition. If it is the highest duty of the park-maker to bring the country into the city, every road and every walk not absolutely needed to make the points of greatest interest and beauty easily accessible is an injury to his scheme, and every building and unnecessary construction of every kind reduces the value of his creation, as do trees and shrubs and other flowering plants which are out of harmony with their surroundings. Such things injure the artistic value of a park; they unnecessarily increase its cost and make the burden of annual maintenance more difficult to bear. Simplicity of design often means a saving of unnecessary expenditure, but it should not mean cheapness of construction. The most expensive parks to maintain are those which have been the most cheaply constructed, for cheap construction means expensive maintenance. Roads and walks should not be made where they are not needed, and they should not be made unnecessarily wide to accommodate possible crowds of another century, but those that are built should be constructed in the most thorough and durable manner possible in order to reduce the cost of future care. When lawns are made the work should be done thoroughly; and no tree or shrub should be planted in any manner but the best and in the most carefully prepared soil. Only as little work as possible should be done, but it should be done in the most permanent manner. The best investment a park-maker can make is in good soil, for without an abundance of good soil it is impossible to produce large and permanent trees and good grass, and the chief value of any park is in its trees and grass; and if the money which has been spent in disfiguring American parks with unnecessary buildings and miscellaneous architectural terrors had been used in buying loam, they would not now present the dreary ranks of starved and stunted trees and the great patches of worn-out turf which too often disfigure them. Only the hardiest trees and shrubs should be used in park-planting, for there is no economy in planting trees or shrubs which are liable to be killed any year, partially if not entirely by frost or heat or drought, which annually ruin many exotic garden plants, nor is it wise to use in public parks plants which, unless carefully watched, are disfigured every year by insects. It costs a great deal of money to cut out dead and dying branches from trees and shrubs, to remove dead trees and fight insects, but work of this sort must be done, unless the selection of plants used to decorate our parks is made with the greatest care. Fortunately, the trees and shrubs which need the least attention, and are therefore the most economical ones to plant, are the best from an artistic point of view; and to produce large effects and such scenery as painters like to transfer to canvas, no great variety of material is needed. The most restful park scenery, and, therefore, the best can be obtained by using judiciously a small number of varieties of the hardiest trees and shrubs, and the wise park-maker will confine his choice to those species which Nature helps him to select, and which, therefore, stand the best chance of permanent success. No park can be beautiful unless the trees which adorn it are healthy, and no tree is healthy which suffers from uncongenial climatic conditions and insufficient nourishment. Even if they are not inharmonious in a natural combination, the trees and shrubs which need constant pruning to keep them from looking shabby are too expensive for park use and should, therefore, be rejected when broad natural effects in construction and economy of maintenance are aimed for by the park-maker.

The sum of the matter of park construction is to make rural city parks less pretentious and artificial in design and to so construct them that the cost of maintenance will be reduced to the minimum. This will save money and lessen the danger of exhibitions of bad taste and encourage that simplicity which should be the controlling motive of sincere art.

MR. BINGER HERMANN, the Commissioner of the General Land Office, devotes considerable space in his first annual report to the discussion of the forest lands of the national domain and the laws under which they are administered; and among other recommendations asks for a large appropriation "to sustain a force of forestry agents to check the work of destruction," arguing in support of this proposition that a "well-managed force of agents would shortly prove more than self-supporting through the proceeds derived from the sale of timber effected by the Government."

The experience of the last twenty-five years has shown what the civil agents of the Interior Department can accomplish in protecting the property of the Government, and the utter futility of trying to enforce the laws of Congress and the regulations of the Department without the aid of soldiers, who have shown over and over again their ability to protect successfully and economically forests in the national parks from fire and pillage after the civil officers of the Interior Department had proved themselves entirely incapable of effective action. The nation's forests need protection badly enough, but it is worse than useless to attempt to protect them with the present methods and machinery of the Interior Department, and money appropriated by Congress for the purpose, unless it is to be expended in furnishing a military or quasi-military control in the forest reserves, will accomplish nothing beyond affording opportunity to the Department to pay good salaries to a few more political hangers-on. Every appropriation of this sort ought to fail.

A better idea of Mr. Binger Hermann's zeal for forest protection than can be obtained from his report will be found in the fact that largely upon his recommendation the great forest reserves of Oregon and Washington have been thrown open to sheep pasturage in direct opposition to the best advice of all scientific men, and with the full knowledge of the destructive effects of pasturage in mountain forests in this and in other countries. This is one of the things which has been done by the present administration for the protection of forests; another is the opening of 19,951,360 acres of reserved forest lands for entry and for personal and corporate stealing during a period of seven months. Discouraging as all this has certainly been, there is comfort to be found for those who believe in the importance of forest preservation in the gradual change of feeling among the people of the west themselves since the discussions which followed the publication of Mr. Cleveland's proclamations of February 22d last, and which much more than anything that has ever been done have called the attention of the public to the importance of preserving the forests of the national domain. We have always believed that the politicians in Washington who shouted the loudest against the reservations represented only a small interested class of the community which elected them, and that the persons who do not live by plundering the Government would, as soon as they understood the meaning and necessity of the reservations, be strongly in favor of them. We are glad, therefore, to find these views confirmed in a recent issue of *Forest and Stream*, which has always been much interested in forest preservation, and is usually well informed on the condition of western forests. "A recent investigation," it says, "of the state of public opinion over a very large portion of the west shows that where a short half-year ago entire communities were bitterly opposed to the establishment of the forest reserves the same communities are now heartily in favor of such an establishment. Where there was bitter hostility there is now cordial friendliness." Nevertheless, it must be borne

in mind, gratifying as this change of public opinion is, that the persons who want to despoil the public domain are rich, organized and represented in Congress, and that it will be difficult to organize the scattered forces of those interested in preserving the forests in time to make their power felt in Washington before all the really valuable forest property of the nation has been destroyed. When this has occurred, and there are no more valuable forests, and nothing more is to be made out of the public domain, the big mining and lumber companies and their Washington representatives will all favor forest preservation.

#### Notes on Cultivated Conifers.—XI.

THE Hemlocks (*Tsuga*) may be recognized by their slender drooping terminal shoots, flat or angled, conspicuously-stalked leaves articulated on persistent bases, which finally become woody, subglobose-stalked staminate flowers produced in the axils of leaves of the previous year, and terminal female flowers maturing in one season into small usually pendulous cones with persistent scales. Of the two sections into which the Hemlock-trees are grouped, the first, *Eutsuga*, is distinguished by its flat obtuse or emarginate leaves, usually stomatose only on the lower surface, and by small cones rarely exceeding an inch in length, while in *Hesperopeuce*, with a single species of western North America, the leaves are acute, convex or keeled above and stomatose on both surfaces, and the cones are from two to nearly four inches in length. The genus, which is now confined to North America, Japan, central China and the Himalayas, consists of seven species, two occurring in eastern North America, two in western North America, one in Japan, one in Japan and China and one in northern India. They are all large trees with thick bark rich in tannic acid and brittle coarse-grained wood.

The Hemlock which is most interesting and valuable to us here in eastern North America is the native *Tsuga Canadensis*, a large tree, generally and widely scattered from Nova Scotia to Minnesota and southward through the northern states and along the high Appalachian Mountains to northern Alabama. The Hemlock, which delights in cool northern slopes, the rocky banks of mountain streams and dark narrow ravines, is one of the most splendid inhabitants of the northern forest. Too much neglected by those who make parks and gardens in the northern states for less beautiful and permanent foreign trees, no other conifer, nevertheless, which can be used here equals it when a specimen is needed to stand alone on a lawn, and with no other tree can such dark dense masses of foliage be made here. Although usually found in the forest on northern slopes or in shaded ravines, the Hemlock will grow in full exposure to the sun; isolated trees, however, suffer from the dry cold winds of the late winter and early spring, and it is usually advisable to protect young trees by thick planting. Quick thinning, however, should follow thick planting, for the Hemlock loses its greatest charm as a lawn-tree when it is deprived of its lowest branches, which, with abundant light and air, are vigorous and long-lived, and make an isolated Hemlock-tree, with its long branches gracefully sweeping the ground, a broad-based pyramid of great beauty. Young trees, which are easily transplanted from the woods, grow rapidly in good soil into handsome specimens, and if planters could only disabuse their minds of the idea that a tree is common, and therefore should not be used in ornamental planting because it grows naturally in their neighborhood, there is no reason why this Hemlock should not become one of the greatest ornaments in all northern parks.

There are a number of abnormal forms of *Tsuga Canadensis* in gardens. The most distinct of them was found about forty years ago on the Fishkill Mountains, in New York, and was first cultivated and made known by Mr. H. W. Sargent. This plant, which is now usually called in gardens Sargent's Hemlock, is a bush about three feet high

with short pendant branches and branchlets, forming a remarkably dense, compact, flat-topped mass of foliage. Several of these plants were originally found together and transplanted, and the largest of them which I have seen is on the Howland estate, in Matteawan, New York, and is now about twenty-five feet across. This variety has been propagated by grafting the branches on the ordinary Hemlock, but in a few years the grafted plants form an erect stem and lose the dense low habit which is the charm of the original seedlings. There are a number of dwarf erect forms of the Hemlock in cultivation and others with branches a little more pendulous than ordinary. On the variety *macrophylla*, which is common in European collections, the leaves are crowded and dark green, and on the variety *albo-spica* the leaves are slightly defaced with pale markings. None of the varieties, however, with the exception of Mr. Sargent's Hemlock, have much to recommend them as ornamental plants, and usually they are prized only by lovers of vegetable monstrosities.

The second Hemlock of eastern North America, *Tsuga Caroliniana*, is distinguished from the better-known *Tsuga Canadensis* by its larger, broader and darker-colored leaves, from six to ten lines long and retuse or often notched at the apex, and by its larger cones with oblong scales longer than wide and spread at maturity nearly at right angles to the axis of the cone. The Carolina Hemlock, which grows usually on dry rocky ridges and the banks of mountain streams mostly at elevations between 2,000 and 2,500 feet above the sea-level, is distributed along the Blue Ridge from south-western Virginia to South Carolina generally in small groves, and frequently mingled with the other species. It is a beautiful tree of compact pyramidal habit, occasionally sixty feet in height, with a trunk rarely exceeding two feet in diameter, and dense dark green lustrous foliage. Sixteen years ago the Carolina Hemlock was first raised in the Arnold Arboretum, where it has proved quite hardy, promising to become here a first-rate ornamental tree. Still rare in gardens, this beautiful Hemlock is now gradually becoming known to the cultivators of ornamental trees.

The noblest of its race, at once the largest and the most graceful of all Hemlocks, *Tsuga Mertensiana* of the north-west coast, has not proved hardy here in New England, although there is still some hope that plants raised from seeds gathered in the exceedingly cold and comparatively dry interior regions of Montana, Idaho or British Columbia, to which this tree extends, may prove more satisfactory here than the plants taken from the warm wet coast region, although a first attempt made in the Arboretum with plants collected by Sereno Watson in Idaho in 1880 has not proved successful.

The second western American species, *Tsuga Pattoni*, the only representative of *Hesperapeuce*, is a tree with pendant branches densely clothed with dark green or with glaucous pale blue foliage and elongated bright purple or light green cones, which are usually pendulous, but in Alaska are occasionally erect, owing to the shortness of the much-thickened branchlets, due, no doubt, to the severity of the climate. Patton's Spruce is a tree of high alpine slopes, only reaching the sea-level, so far as is now known, in the neighborhood of Sitka, on Baranoff Island, and ranges from about latitude sixty degrees north southward along the high coast mountains, extending eastward in British Columbia to the Selkirks, and in the United States to the Cœur d'Alene and Bitter Root Mountains of Idaho and to northern Montana, and southward along the Sierra Nevada, where it is rarely seen below elevations of 10,000 feet above the sea-level. Patton's Spruce, with its drooping leading shoots and pendant branches clothed with slender waving spray which hide strength to withstand the fiercest mountain gales and the heaviest burdens of enveloping snow, is certainly the most beautiful of the alpine trees of this continent. Introduced into Europe about fifty years ago, it has proved hardy there, as it has on the Atlantic seaboard of New England. Here, how-

ever, like most alpine trees, it grows very slowly and still retains its dense pyramidal juvenile habit.

In Japan Hemlock-trees are common at high elevations, and the coniferous forests which cover the mountain ranges of central Hondo above 5,000 feet are chiefly composed of these trees and of Birches. Of the two species which inhabit Hondo, *Tsuga diversifolia* is the more northern and the larger tree. It is this tree which grows on the Nikkō Mountains above Lake Umoto (see GARDEN AND FOREST, vol. vi., f. 73), and which ranges as far north as the slopes of Mount Hakkoda, near Aomori. The second Japanese species, *Tsuga Araragi* (the *Tsuga Sieboldi* of many authors and the *Tsuga Tsuga* of others), is a more southern and a smaller tree, growing, as I saw it on Mount Komagata, in scattered groves among deciduous-leaved trees and *Pinus densiflora* and not in continuous forests. *Tsuga diversifolia*, which is frequently eighty feet in height, with a trunk three or four feet in diameter, may be distinguished from the southern tree by its darker red bark, more slender branchlets covered with fine rufous pubescence, by its shorter and narrower leaves and much smaller cones which are rarely more than half an inch in length; while the longer, broader and more lustrous leaves and smooth lustrous orange-brown branchlets of *Tsuga Araragi* serve to distinguish the southern tree before it begins to bear cones, which are nearly an inch long. (See figures 62 and 63 on pages 492 and 493 of this issue, made from plants in the neighborhood of Boston.)

The two Japanese Hemlocks are successfully cultivated by Mr. Hunnewell in his pinetum at Wellesley, where they are both hardy and where there are fine plants of *Tsuga Araragi*, the largest being about sixteen feet in height, and smaller specimens of *Tsuga diversifolia*. Most of the Japanese Hemlocks in our gardens, however, belong to the northern species, which, although probably hardier, is a less attractive tree than *Tsuga Araragi*. This with its large lustrous leaves and excellent habit is certainly one of the most beautiful of the Hemlocks which are hardy in this climate, and if it proves its ability on a longer trial to maintain itself here in good condition, it will doubtless become a popular ornament of American gardens. *Tsuga diversifolia* is a less beautiful tree than our native Hemlock, and, unless it develops qualities which it has not shown yet in this country, it will probably never be very popular here.

The Hemlock with pubescent shoots and small cones found by Dr. Augustine Henry in the province of Hupeh, in central China, is probably the northern Japanese species, although the leaves of the Chinese plant are rather longer than those of the Japanese tree.

*Tsuga dumosa*, the Himalayan Hemlock, is scattered from Kumaon to Bootan at elevations between 8,000 and 10,500 feet above the sea-level, and is a noble tree occasionally 120 feet in height, with a trunk seven or eight feet in diameter, and longer leaves than those of the other species. I have never seen a specimen in the United States, and in Europe the Indian Hemlock has not grown particularly well.

C. S. S.

#### The Cultivation of Citrus Fruits in California.

THE outlook for the Citrus-fruit growers of California for the coming season is the best in the history of the industry. The crop will be the largest. The fruit has now attained a reputation in eastern markets such as it has never had before, times are easier than at any period for the past few years, and tariff protection will give California growers an advantage not previously enjoyed. This advantage will be partially offset by a reduction of freight charges on fruit from the Mediterranean, but will still be appreciable. Under these conditions an outline of the development of Citrus-fruit culture, as a commercial industry in California, may be of interest.

Orange and Lemon trees are growing in nearly all of the counties of the state not exclusively in the mountainous sections, and many of these trees are bearing more or less fruit of very fair quality. For climatic reasons, however, the Citrus-fruit industry is and must be confined to a belt of country lying among the foot-hills of the Sierra Nevada mountains, and called the thermal belt. It stretches from San Diego to Tehama

County, a distance of over 700 miles, and varies in width from three or four miles to twenty-five or thirty. It is estimated that there are in this belt about a million and a half acres of land adapted to the safe cultivation of citrus fruits on a commercial basis, but whether all of this land is susceptible of irrigation is still undetermined.

The altitude ranges from 300 to 1,800 feet above sea-level. The mean summer temperature of this belt is somewhat higher in the northern portion than in the southern; but the mean winter temperature is higher in the southern than in the northern portion. The mean temperature for the year does not vary more than four degrees throughout the whole belt. The warmer temperature in the northern section during the growing season favors the earlier ripening of the fruit, while the warmer winter temperature in the southern section favors a safer and more general development of the industry.

All along this belt of country are especially protected or favored localities and also localities where it would be unsafe to attempt Citrus-fruit culture as a commercial enterprise. This is caused by the local topography of the country and does not depend much on the altitude. Wherever cold currents of air from high altitudes flow to the valley without interruption it

further north, where this range is practically unbroken and the Citrus belt is farther inland. These disadvantages of the northern section are, however, somewhat counteracted by the fact that the drier and warmer summer atmosphere is a greater guarantee against the spread and damages of insect pests. The more elevated inland localities in the south have this same advantage over localities nearer the coast.

From the best information obtainable some Oranges were planted in the Mission San Gabriel, Los Angeles County, in the year 1804. The nucleus of Orange culture in California was formed in this place and at about the above date by Padre, or Father, Sanches. The second trees were planted in Los Angeles by Don Louis Vignes in 1834. Several other small plantings followed about that date, but no orchards were planted with a view to selling the fruit till the coming of American people to California. The historic orchard of William Woltskill, at Los Angeles, was the first planted with an idea of profit and he was the subject of ridicule when it was learned by his neighbors that he entertained this idea. When he died he had a bearing orchard of twenty-eight acres and that year the fruit was sold on the trees for \$25,000. A few trees were planted at Old San Bernardino by L. Van Leuven, in 1857, from seed grown

Fig. 62.—*Tsuga Araragi*.—See page 490.

would not be safe to attempt Citrus culture at any elevation within the sweep of these currents. On the other hand, wherever these descending currents are cut off or turned aside by spurs of the mountains, leaving the warm atmosphere of the day undisturbed during the night, there Orange and Lemon culture may be engaged in without danger from frost. In other words, the eddies of air currents must be selected and the main flow of these currents must be avoided.

Every one who has traveled along these Sierra foot-hills parallel with the valleys, particularly in the winter season and at night, will recall his surprise at the sudden changes in the temperature of the atmosphere within short distances. He may also remember to have noticed tender plants and shrubs seared and frost-bitten, although just over a ridge or cone the same plants or shrubs were in full leaf and growing luxuriantly. Want of attention to these facts has caused many disastrous failures in the cultivation of Citrus fruits in California.

It may be here observed that these peculiar natural phenomena are more striking and their lessons are more imperative north than south of the Tehachapi pass—for the reason that south of that point the coast range of mountains is broken up into fragments and the tempering influences of the waters and breezes of the ocean are more direct and powerful than

by him. He also planted the same year forty-five trees obtained from Los Angeles. About two hundred were planted at Crafton by Myron H. Crafts about 1865. The first seeds were planted at Riverside in 1870, and the first trees in orchard grown from these seeds, in 1872 and 1873. In 1869 Frank A. Kimball planted some Orange and Lemon trees at National City, San Diego County. At that time there were two old Orange-trees growing in El Cajon valley. In 1862 H. M. White planted two Orange-trees in Frazier Valley, east of Porterville, Tulare County. The first orchard was planted in Porterville in 1883 by A. R. Henry. About the same date a small planting was made at Centerville, Fresno County. Some time in the sixties the noted tree at Bidwell's Bar, on the Feather River, in Butte County, was planted. The seed from which this tree was grown was planted by Jesse Morrill in his garden in Sacramento. A few trees were planted in his garden by the agent of the Marysville and Oroville Railroad as early as 1868 at Oroville, Butte County. Thus we find that as early as 1870 small Orange groves had been planted all along the foot-hills from San Diego to Butte County. Plantings in many of the valley counties had also been made up to this date, but these latter have served to prove the inadaptability of the valleys to the growth of the industry,

while on the foot-hills the small beginnings have developed into one of the most permanent and profitable branches of horticulture in the state.

Although in early years the increase in planting, except in Los Angeles County, was quite slow, of late years it has been more rapid. In 1881, by official returns, the whole number of trees in the state was: Orange, 484,227, and Lemon, 62,130. Of these Los Angeles County had 450,125 of Orange and 48,350 of Lemon trees. Estimates of the number of Orange-trees now in the state vary between four millions and eight millions. There are of Lemon-trees one and a half millions. In 1879 Los Angeles County shipped fifteen cars of oranges out of the state. In 1890 there were shipped from the state 3,429 cars, mostly from three southern counties. By careful estimate California has this season to ship 12,000 cars of oranges and 1,500 cars of lemons. The receipts for oranges in 1890 to 1891 were \$1,796,025. This season, at the same prices, the state should receive for oranges \$6,300,000, and for lemons \$675,000, a total of \$6,975,000. The shipments this season will go from thirteen counties—San Diego, Riverside, San Bernardino, Santa Barbara, Ventura, Orange, Los Angeles, Tulare, Fresno, Sacramento, Placer, Butte and Tehama.

I have given the accepted estimate of this season's crop

it could not have been very sweet and ripe. But the trade seems to demand these early shipments, and prices have been steady at \$3.00 for best Navels, and \$2.00 for best seedlings.

An innovation in marketing fruit has been established at Redlands, the results of which will be watched by growers with great interest. This is an effort to give growers and packers an equal voice in establishing the prices of oranges from time to time through the selling season, and to eliminate, as far as possible, the element of competition among the packers of this locality. It is believed that this effort will result in higher prices to the growers. An association known as the Redlands Citrus Union has been organized, with a general committee consisting of one representative from each firm of packers, one from the patrons of each firm among the growers, and five members of the Redlands Horticultural Club, an organization which has as its objects the general horticultural interests of the city. This general committee will meet from time to time to fix the minimum price at which the oranges of this section shall be sold. The packers have agreed, in writing, to abide by the price so fixed. This is an extension of the principle of coöperation which has already aided in bringing the Redlands oranges reputation and high prices. The experiment is regarded with favor by all those interested, and

Fig. 63.—*Tsuga diversifolia*.—See page 490.

of oranges at 12,000 cars, but another reasonable estimate is 14,000 cars. If climatic conditions continue favorable the output will probably reach the latter figure. There will be a larger quantity of the best fruit than ever before, as the crop in those districts which produce the best will be largely increased. Riverside will have 4,000 cars instead of the 2,600 of last year; Redlands, 1,200 in place of 700; Ontario will increase seventy-five per cent, and the San Gabriel Valley expects double the crop of last year. The crop from the northern districts will probably not exceed 1,000 cars this year. But Tulare County is rapidly coming to the front as an Orange-growing section, and will soon be a noteworthy factor in the situation. It is interesting to note that this section and Redlands, both of which now grow fine oranges, were long considered unsuitable for Citrus culture: Tulare because it is so far north; Redlands because its northern slopes and heavy, red, clayey soil had not been tested. The two districts are at least 200 miles apart as the crow flies.

Early shipments have already gone forward from several localities; from Porterville and other places in the north; from Azusa, Covina and Highlands in the south, and shipping will be active from now on. The first carload was sent from Highlands October 23d. This is very early, and, although the fruit may have been well colored and pleasing in appearance,

will undoubtedly receive a careful trial. Other localities are investigating its merits with a view to its adoption.

Some of the facts stated in this article with respect to the history and the limits of the cultivation of Citrus fruits in California were collected while engaged in work with Mr. I. N. Hoag.

## Foreign Correspondence.

### London Letter.

BEGONIA GLOIRE DE LORRAINE.—At the risk of overdoing, I must again praise this beautiful plant. It has been a feature at every exhibition I have seen during the last two months; it has been and is the principal attraction in many gardens where warm-house plants are grown, and it is admired by all classes, even the Chrysanthemum worshippers stopping to praise it. Fogs do not appreciably hurt it, and it continues to flower all winter, its elegant flowers, colored bright rose-pink, being most decorative and useful in various ways. Scores of fine examples of it were shown at the last meeting of the Royal Horticultural Society.

**BEGONIA MRS. HEAL.**—This new hybrid, recently sent out by Messrs. Veitch, was shown in fine condition at this meeting, and plants a foot or so high showed fleshy dark green leaves six inches across and tall erect scapes with flowers two inches or more across and of the richest scarlet color. A second hybrid of the same parentage and origin was shown under the name of Julius. This is remarkable for its double, Carnation-like pale pink flowers, borne on nodding scapes and measuring nearly two inches across. It received an award of merit.

**CARNATION WINTER SCARLET.**—This useful addition to bright-colored winter-flowering Carnations was shown by Messrs. H. Low & Co., who have a large stock of it. It is superior to Winter Gem in its habit of flowering earlier, the latter being at its best in early spring, whereas this new variety is in perfection in November. It forms a compact plant eighteen inches high, with short, narrow foliage and numerous well-formed full flowers of a rich, glowing scarlet color.

**ALBERTA MAGNA.**—A bush of this handsome Rubiaceae plant from Natal is now an attraction in a warm greenhouse at Kew. I have before noticed this plant when it flowered in a pot in a cold house, but it is much superior now after having been grown in an intermediate temperature and planted out. The leaves are as large and glossy as those of the common Laurel, and the terminal-branched racemes of bright crimson tubular flowers are thrice as large and much more effective than those borne by pot-grown plants. Flowering in winter, too, the plant is all the more valuable. I anticipate for it considerable popularity when it becomes better known.

**HYBRID ORCHIDS.**—These were largely represented at the last meeting of the Royal Horticultural Society. Mr. Chamberlain sent Cattleyas and Lælias, among them a beautiful hybrid between *C. Dowiana* and *L. præstans*, in which the broad mauve-colored segments and the large open-cripsed labellum, colored maroon-crimson, with streaks of a darker shade and a few splashes of yellow, were peculiarly attractive. Messrs. Linden showed *Cypripedium Beekmani*, said to be a hybrid between *C. Boxalli* and *C. bellatulum*, but showing little of the character of the latter, although quite different from and vastly superior to any form of *C. Boxalli*. The flower is very large and richly colored. *C. insigne luciani*, from the same exhibitors, is a near approach to the greatly treasured *C. insigne Sanderæ*. Messrs. Veitch & Sons showed *Lælia Olivia*, a hybrid between *L. xanthina* and *L. crispa*, and fairly intermediate in form and colors. *Cattleya labiata*, White Queen, is the best white form of this *Cattleya* that I have seen. *Cypripedium Deedmanianum*, raised in the Birmingham Botanic Garden from *C. Chamberlaini* and *C. Spicerianum*, has a scape nine inches long, with a flower in which the dorsal sepal is not unlike that of the latter parent, while the rest of the flower resembles in form and color the remarkable *Chamberlaini*.

**MUSHROOM CULTURE.**—The demand for mushrooms at all times of the year is a great and increasing one. Their cultivation has, therefore, become an important industry in the neighborhood of large towns, and particularly of London, where there are now numerous large market-gardens in which Mushroom culture is practiced on an extensive scale. The outdoor ridge method and the indoor shed method are practiced, and while the latter is, perhaps, somewhat more costly, the mushrooms thus produced are cleaner and generally better in flavor than those grown on ridges. I have lately had an opportunity of inspecting one of the largest of these Mushroom farms, that of Mr. Tebbutt, in Isleworth, near Richmond, who kindly gave me particulars of his methods, which I think may be of interest to readers of GARDEN AND FOREST.

**CULTIVATION IN THE OPEN AIR.**—The ridges or raised beds are formed by arranging specially prepared horse-manure in mounds about a yard wide at the base and a yard high, narrowing it gradually from the base upward. These ridges may be any length to suit the convenience of the ground. The manure must be fresh horse-droppings and straw, and the better the food the horses have been fed

upon the better the results will be. Manure from the stables of corn-fed horses is much superior to that from stables where the food is chiefly grass or hay and otherwise poor. This manure is turned three or four times before it is made into ridges. It is well shaken, pressed with forks and trodden down firmly as the ridge is being formed. The sides are then combed with forks and beaten with spades or forks. When finished it looks like a long ridge of straw arranged to throw off the rain. The temperature of the ridge must now be watched, as inserting the spawn in too great a heat would mean inevitable failure. When the temperature of the manure an inch or so below the surface has fallen to about eighty degrees pieces of spawn-brick two inches long and wide are inserted about nine inches apart all over the surface of the ridge. Two or three days later the ridge is coated with about two inches of soil, which is put on wet and beaten with spades, a good clayey loam being preferable to any other, although ordinary garden soil will serve. The ridge is then covered with straw litter; the longest of that taken from the manure heap when it is being turned is generally used. In cold weather this covering may be twelve inches thick, but in mild weather less will do. The temperature on the surface of the soil should be maintained at about sixty degrees. In from six to eight weeks the first crop of mushrooms will be up, and if the ridge is well made a continuous supply will be yielded for from eight to twelve months. The estimated cost of these ridges, including labor, rent, etc., is about five shillings for each lineal yard, while the yield of mushrooms from a yard is from twelve to fifteen pounds, the average value of which is one shilling a pound.

**CULTIVATION UNDER COVER.**—The method of growing Mushrooms in large sheds or barns is as follows: The shed is divided into floors or shelves of wood four or five feet apart, with passages for convenience of working. Hot-water pipes are arranged for the purpose of keeping the requisite surface temperature in winter; the covering of litter is thus dispensed with. The manure is prepared in the same manner as for the ridges. It is then put on the floors or shelves, pressed down firmly, and when finished the layer of manure is from nine inches to a foot thick. The beds are spawned when the temperature is about eighty degrees, and a coating of wet clayey soil is placed over all and pressed down firmly with a wet board or the back of a spade. The mushrooms thus grown are perfectly free from litter or soil of any kind, and when placed in the punnets ready for market they are as white and smooth as eggs. Mr. Tebbutt grew two tons of mushrooms in an old barn last year, and he has this year built a shed about fifty by twenty-five feet, containing four layers of shelves or floors from which he expects four tons of mushrooms. During the winter and spring as much as two shillings a pound is not an unusual price for these first-grade mushrooms.

It is generally supposed that frost destroys the mycelium or spawn of the mushroom if allowed to get to these artificial beds, but Mr. Tebbutt has proved that frost does no harm beyond retarding the growth. Beds which had been frozen through in severe weather have yielded a good crop when brought on again by coatings and linings of fresh manure.

Many old disused buildings could be made to do good work by turning them into mushroom houses, and given good spawn, properly prepared stable-manure and intelligent management the production of mushrooms by the ton does not appear difficult of accomplishment.

London.

W. Watson.

We are accustomed to speak of urban parks as the lungs of cities, but the ideal park is more than a laboratory for purifying the air. It does more than offer an invitation to agreeable physical exercise and a change of mental occupation. Contact with and contemplation of natural scenery, especially of pastoral scenery, brings positive refreshment to the mind. Green pastures and still waters now, as in the days of the Hebrew poet, restore the soul. This is a fundamental truth, and, therefore, it has profound practical importance.—W. A. Stiles.

## Cultural Department.

### New Vegetables.

**Gregory's Surprise Pea.**—This is an American variety said to have resulted from cross-breeding the Earliest of All and the American Wonder. The vine and leaf resemble those of the first sort. The green and dry peas are much like those of American Wonder, while the pod is intermediate in character. I have had it under observation in a small way for three seasons, and with me the comparatively slender vine grows to the height of about two and a half feet, does not branch, and bears its pods singly, the lower one at the seventh to the ninth node. The earliest pods have become fit for use a little before those of the Earliest of All, but it has not furnished a picking any sooner nor has it matured all of its crop quite so early. With me the vine has not been quite so hardy, vigorous or productive as the Earliest of All, but the difference has been so slight as to be of no practical importance. The pods are a little shorter and more cylindrical than those of the Earliest of All and a little less in diameter than those of the American Wonder, and they are less attractive. The green peas are much the best in quality of any of the first early sorts, and superior in sweetness, tenderness and flavor to those of the Station, Eclipse or Gradus. They are better even than Alpha, and, of course, incomparably better than any of the smooth and hard sorts like Earliest of All and First and Best. When ripe they resemble those of the Alpha, being quite as small and wrinkled, but a little more square in shape and a trifle darker in color. I have not had an opportunity to see the variety under field cultivation, and it is hardly fair to judge of the purity and evenness of stock from the small quantities I have seen grown, which have been very good in these respects. It is reputed to come true and to show little tendency to sport. I question whether this will become a popular sort on the market because of its comparatively small and unattractive pods, but it will be welcomed by those whose judgment is not unduly influenced by appearances as a really good first early pea. As far as I can judge from my limited acquaintance with it this is the best first early for the home garden which has yet been produced.

**The Gradus Pea.**—This variety has been in cultivation in England for several years, but the quantity obtainable has been so small that the past season was the first that it has been extensively tried in this country. The vine grows to the height of from two to three and a half feet, is a little coarse-stemmed, with rather long nodes, and usually bears from four to six large, and two to three smaller pods, the lower one from about the eighth node. It rarely branches, even when given plenty of room, and has not proved with me very hardy or productive, but is better in both these respects than the Telephone was on its first introduction. I believe that stock grown for a few generations in this country will show even greater improvement in these respects than has developed in that variety. The pods first formed can be used about the same time as those of the Alaska or a good strain of Extra Early, but the crop does not mature so early or evenly, and will generally require several pickings to secure it. The individual pods remain in good condition much longer than those of most early sorts. The leaves are above medium size and the stipules are very large, so large as to distinguish the variety from all others, especially as they are a distinct light yellowish green color. The pods in size, shape and color closely resemble those of the Telephone, and are quite as handsome and attractive. They usually contain six to eight peas, and occasionally one is found having as many as ten. The green peas are very large, light bright green, oval in shape, and I think are sweeter and more tender than those of the Telephone. The dry peas are above medium size, coarsely and deeply wrinkled, and when well harvested and cured are a light green color, though if exposed to the sun in harvesting they bleach to a bright light yellow. Most of the stocks we have seen are much more pure and true than one can usually obtain of the newer English sorts, and with me the variety has shown little tendency to sport or run off in type. I am not certain what the future of this new Pea will be. Its earliness, the large size and beautiful appearance of the pod, and the excellent quality of the peas make it a most desirable sort for the market gardener, but its slow maturing, so that it requires a number of pickings to gather the crop, and its habit of growth, which calls for a liberal use of seed, are against it as a commercial variety. But these very qualities are in its favor for use in the home garden, and I think that it will find many friends among amateur gardeners and become extremely popular.

**Golden Hubbard Squash.**—This new squash has been before the public for two years and has proved to be a distinct and

fairly well-fixed variety of evident merit. The vine is vigorous and hardy, in general character like that of Hubbard, but on our rich soils it does not grow quite so rank, and in such cases instead of expending its surplus energy in the production of a few overgrown specimens it tends rather to develop a greater number of fruits of normal size. It matures some of its fruits quite early, nearly as early as the Prolific Marrow, and with me has always given a large crop, which has ripened before and much more uniformly than the Hubbard. The fruits are about the size and shape of a small and rather long Hubbard squash, the length coming from the projections at the stem and blossom ends being rather longer, and they are also generally more curved. It is very hard-shelled and uniformly warty, though the protuberances are smaller and less pronounced than in a warty Hubbard, and the projections at each end are smooth-skinned. When ripe the color is a rich orange-red, of a deeper and redder tint than that of Prolific Marrow, and about one and a half inches of the blossom end is dull olive-green, like a light-colored Hubbard. Some fruits show narrow, indistinct lighter stripes running from the blossom end, similar to those which the seed breeders have tried so hard to get rid of in the Hubbard. With me these fruits have proved as good or better keepers than those of the old sort. The flesh is a deep rich reddish orange color, darker than that of any winter squash I know, very fine-grained and brittle, and I have never seen one which was coarse-grained or had the objectionable green dots and shades found near the skin in most Hubbard squashes. The flesh is, however, only moderately thick, and the sort can probably be improved in this respect by selection. When cooked the flesh is very dry, often rather too much so, of fine color and grain, sweet and good-flavored, practically like that of the Hubbard, though if I were obliged to decide between the two on this point I should give the choice to the older sort.

Since the Hubbard squash was first introduced every few years there has appeared some new variety which it was claimed was better in some respects and just as good in all other particulars, and sure to displace the old sort. But after a few years' trial each of these has disappeared to be followed by another sort with the same history. To-day the majority of gardeners and consumers regard the Hubbard as by far the best winter squash, and I am not bold enough to say that it will ever give place to the Golden Hubbard or any other sort. It seems to me, however, that this new variety has some advantages over the old; it is more desirable in size and it is more uniform in this respect; it matures earlier and more uniformly; the exterior color is far more attractive than the dead green of the old sort; the flesh when cooked is of much better color and is practically the same in quality. It seems to me that the old stock may have to give way to an improved and beautiful descendant.

Detroit, Mich.

Will W. Tracy.

### Amaryllis.

**THOSE** who saw the magnificent lot of seedling Amaryllis exhibited by Mr. Kenneth Findlayson, gardener for Dr. Weld, Brookline, which were shown in Horticultural Hall, Boston, last spring, will not soon forget it. These gorgeous bulbous plants have been imported at high prices from European raisers. There has been little thought of the possibilities of procuring stock at home. A beginning has been made in southern California, where the climate is favorable, to grow seedlings for the trade supply. The finest varieties, however, do not come in wholesale lots, and it is only by thorough and persistent effort that they are obtainable.

As the season for these remarkable flowers approaches, some account of the methods of seeding and raising them may be timely. To cultivators who can find the time required this will prove an interesting occupation. The flowers do not appear to be self-fertilizing. No seeds are produced unless the work is done artificially. The stamens are always ready before the pistils, whose tips reflex, becoming triclavate and gummy before they are ready to receive the pollen. But as the pollen will keep some time after it is ripe I always take the stamens off before crossing them with other pollen. To indicate how long pollen will keep fresh I was at North Easton one Friday, where the late Mr. William Robinson had some choice varieties in bloom; he kindly packed some stamens in tissue paper, which I put in my pocket, and forgot until the following Sunday. This pollen took well, and now I have a fine batch of seedlings which will flower this winter and spring from these crosses. When the pollen has taken the flowers drop and the capsules swell at once. It takes about six weeks for them to mature, and when ready they open longitudinally. As many as fifty seeds may be produced from a single capsule, and

these will be ready for sowing a few days afterward. I use pans of light soil, setting the seeds with the thin point downward. Light watering and a moderate temperature are sufficient, and the seedlings will be up in from four to five weeks. They may be pricked off in the ordinary way, and will make nice bulbs, though not large enough to flower the first season. Some growers have planted them out for the summer, though the most successful practice I have seen has been to keep them in pots; six-inch size will be large enough until they bloom. Mr. Findlayson's *Amaryllises* were kept indoors all the time, but this was principally to avoid the *Narcissus-fly* grub, which has been destructive lately. Until they flower they should be kept growing, but afterward they may be rested annually in the ordinary way.

Wellesley, Mass.

T. D. Hatfield.

### More Orchid-flowering Cannas.

PANDORA is another of the Orchid-flowering Cannas from the list of Dammann & Co. We have the variety from the originators, and have been enjoying its blossoms in the greenhouse since September. The plant is dwarf, growing about three feet high. But these are young plants closely potted in the house, so that we may expect a larger growth of strong plants out-of-doors. The foliage is very dark red, splashed with lighter greenish red. The flowers most closely resemble those of *America*, described in *GARDEN AND FOREST*, vol. x., p. 178, with the attractive, full-rounded form of those of *Italia*, with reflexed petals (not staminodia). The petal-like staminodia are bright, fiery cherry-red, heavily splashed and overlaid with a darker velvety red, giving a peculiarly rich appearance. Pandora and *America* please us the best of all the Italian or Orchid-flowering sorts.

The varieties *Bavaria* and *Burgundia* (Dammann) have also been in blossom with us since September 13th. These are both of comparatively dwarf habit, the foliage being smaller and narrower than in the better-known *Italia*, *Austria* and *Burbank*. They both give blossoms of the *Italia* type, it being frequently difficult or entirely impossible to separate the three, *Bavaria*, *Burgundia* and *Italia*, by the blossoms alone. *Bavaria* tends to have more solid red at the centre, so that it becomes rather a yellow-bordered flower, of somewhat the same marking as *Queen Charlotte*; *Burgundia* is more spotted and looks a trifle more like *Florence Vaughan*; *Bavaria* usually has upright petals, while *Burgundia* commonly shows its *Canna flaccida* parentage in reflexed petals.

We had *Italia* and *Austria* in large beds on the open lawn throughout the summer, where they gave moderate satisfaction. Their large growth and heavy luxuriant leaves give a fresh, semitropical foliage effect worth consideration; but the blossoms are not, upon outdoor plants, an item of much importance.

## Correspondence.

### Ideals of Horticultural Instruction.

To the Editor of *GARDEN AND FOREST*:

Sir,—At a recent meeting of the Horticultural Seminar, to which reference was recently made in *GARDEN AND FOREST* (page 438), Professor F. A. Waugh, in the course of a paper on Ideals of Horticultural Instruction, said that in the fourth decade of this century Poiteau, an eminent French horticulturist, published what he considered an ideal course of study for horticultural students. It comprehended instruction in the elementary principles of those natural sciences having a technical application in horticulture, horticultural methods and an introduction to the literature of the subject. The end in view was the acquirement of technical skill.

Present notions of horticultural instruction in many schools are similar in ideals to those held by Poiteau. Obviously, related natural sciences, especially systematic and physiological botany, should precede a course in horticulture. With a course thus arranged, the instructor can pursue his ideal, that of technical instruction. But in some colleges horticulture is prematurely introduced before the prerequisites have been taken; hence more or less of the time that should be devoted to horticulture proper is necessarily spent in giving instruction that should have been previously given in other courses. This is a serious hindrance to the cause of horticultural instruction. In recent years, a few instructors, following Professor Bailey, of Cornell, have been influenced by quite different ideals. These men teach horticulture not merely for horticulture's sake, that is, for immediate practical results, but also, and this primarily, as a disciplinary

study in a scheme of liberal education. The former aspect of the subject belongs to technology, and can be taught to children in the industrial schools. The functions and purposes of a college course are different. Here the aim is to teach the student "to observe, to reason accurately, to present his thoughts cogently," and to cultivate the æsthetic tastes; in a word, the development of the mature man. In order to merit a place in a college curriculum, horticulture must confine itself within the scope of college instruction and must be subordinated to its aims. It must conform to the methods and requirements of liberal education in so far as the subject will permit.

Professor Waugh said there are three broad divisions of horticulture, each laid in a different field of knowledge: (1) a science, a branch of botanical science; (2) a philosophy, based on the science, and typified in the evolution course; (3) an art, illustrated in landscape-gardening. But art, science and philosophy are the basis of all university instruction. In such a course as is here advocated, while the student is adding to his general education, he is at the same time developing in sympathy with horticultural pursuits, and gaining an acquaintance with a valuable trade.

Those who follow Poiteau's ideal cultivate the practical side of the subject, in preference to the liberal aspect; their ideal is an institute of horticultural technology. The followers of Professor Bailey bring into the foreground the requirements of a liberal education; and while they teach technology, treat it as of secondary importance. Horticulture is a required study in agricultural colleges generally. For students who do not follow that occupation in after years, the technology is of comparatively little value; while the student who pursues a course shaped according to the second ideal develops in a manner to increase his satisfaction in life, whatever his surroundings may prove to be.

We may apply to horticultural instruction an epigrammatic statement made by President Fairchild, of Kansas, in his address at the Minneapolis meeting of the American Association of Agricultural Colleges, as to the development of agricultural education: "The ideal of agricultural education was first, education *for* agriculture; second, education *in* agriculture; third, education *by* agriculture." This characterization points out a real progress and the different stages of development are each marked.

In a short discussion that followed the reading of the above paper, Professor Waugh expressed his conviction that the greatest need in agricultural education to-day is that of High Schools that shall fit men simply for practical agriculture; and that the next step in agricultural education would be the establishment of such schools.

### Chrysanthemums in Boston.

To the Editor of *GARDEN AND FOREST*:

Sir,—At the recent exhibition of Chrysanthemums in Boston it was more than ever apparent that large flowers with strong stems were most popular. The florists' ideal was supreme; and the large vase of magnificent flowers of Mrs. Jerome Jones, shown by E. M. Wood & Co., was the centre of attraction. These were each of the same size, and arranged with such precision that the whole presented an even and rounded mass. That this was in keeping with the popular taste was evident from the frequent comments on other vases which did not show this regularity. There was one, however, in some respects a departure, arranged by Mr. John Ash, gardener for Mrs. Clark, of Pomfret, Connecticut, which the committee recognized by an award, though there were larger flowers in competing vases. While the arrangement of the blooms in all the other vases was uniformly even, and generally conceded to be effective, it was shown by the awards by the committee on plants that the matter of arrangement can be carried to excess. The groups arranged for effect were circular pyramids of single-flowered plants which followed, with one exception, the even plan of arrangement adopted in the vases. Kenneth Findlayson, gardener for Dr. Weld, of Brookline, effectively broke this monotony in his group by the use of a few separate plants, and was rewarded for his efforts.

Complaint is frequently made that naturally grown plants are not seen. The fact is that but few varieties are suitable for growing in this way. Plants like *Norma*, *Golden Ball* and many of the pompones stand up well, but the greater number would be accounted untidy if grown naturally. It seems to me there can be no halfway between a natural and a trained specimen. The greatest perfection in training is neatness and finish, just what we complain of when we want an artistic vase

of blooms. Those plants are adjudged best which are symmetrical in form and produce a mass of color. The decisions of the National Committee on Chrysanthemums judged by blooms alone, show that the deeply built incurved flowers which are well adapted for shipping, have been favored most, and even in the class for private growers few others have been recognized, though it may be that few have been offered. It will be seen, further, that when the grower of specimen plants must make his choice from blooms alone, and of this description, he finds few which are really suitable. If he is wise he will keep what is good among the older varieties, though he may be rated behind the times in consequence. Incurved varieties do not make as effective plants as reflexed ones; and when a large number of flowers have to be grown on a plant they are apt to be out of character. Sometimes the flowers are heavy, and the stems need to be supported close up to the flower. This gives a stiffness of arrangement which is far from effective. Experience shows that flowers belonging to the reflexed class, like President Hyde, Cullingfordii and W. H. Lincoln, make the best specimens and keep their character longest.

The Forest.

Willows at Chico Forestry Station.

THE Willows receive as yet little attention in California, and the value of our native species is not recognized as fully as it should be, although *Salix lasiandra*, which closely resembles *S. lucida*, *S. lasiolepis*, which somewhat resembles *S. humilis*, and the more distinct *S. lævigata*, all native in this state, are often planted for firewood and fencing. The best of the famous Spanish hand-made saddle-trees which were formerly produced in various parts of California and were even shipped to Mexico and Texas, were made of native willow wood, carefully selected and seasoned.

In time there will probably be an extensive demand for basket willows in California, especially for horticultural uses. *Salix viminalis* and other soft-wooded Osier Willows have been widely distributed for fifteen or twenty years by the Agricultural Department of the University, and have been planted in many places to protect levees and river banks. Aside from these Osiers, from *S. Babylonica*, and from the native Willows, nothing has been done with Willows in any part of California, although there is now more or less inquiry respecting the best species for cultivation.

The following brief notes upon various Willows planted at Chico Forestry Station were taken late in August of this year, when the season's growth, although not completed, was in most cases nearly so.

Our collection was begun in the spring of 1895 by planting in nursery small cuttings of twenty-four selected species received by mail. The soil is a good Corn land loam, near Chico Creek. Several native species of Willow are on similar soil, within a stone's throw. Again, in 1896 and in 1897, others were added to the collection, which now contains about forty species.

In February, 1896, from five to ten plants of each of the twenty-four species obtained in 1895 were set out in permanent plantation form. They received no irrigation, nor any especial care. The Willows in this plantation are, therefore, about thirty months old from small cuttings. The list includes *Salix alba*, *S. caprea*, *S. cordata*, *S. discolor*, *S. hippophaefolia*, *S. Japonica*, *S. Madeni*, *S. pentandra*, *S. purpurea*, *S. Salmoni*, *S. sericea*, *S. Sieboldii*, *S. Villarsiana*, *S. viminalis*, *S. daphnoides*, *S. dasyclades*, *S. regalis*, *S. lucida*, *S. serengeana*, *S. Babylonica*, *S. nigra*, *S. humilis*, *S. alba vitellina* and *S. caprea*, var. *cinerea*. Many of these Willows are beautiful in growth, and especially handsome in winter and spring. But since the collection was made in order to introduce the most useful species, I shall only describe those which seem particularly well adapted to California.

The Willow which shows the most remarkable growth is *Salix Salmoni*, a native of the Levant. This species in that

respect much surpasses all our native Willows as well as all others in the plantation. In the nursery the cuttings made roots and thrust up stems of ten feet in length within six months after planting. Five selected trees were cut back to one stem of two feet in height, and planted out in February, 1896. Now, in August, 1897, two of these trees stand respectively thirty-one and thirty-two feet in height, with trunks that exceed eighteen inches in girth at two feet from the ground. The other three are nearly as large. All five trees are beautiful in shape, with the straightest of main stems and with slender, semidrooping branchlets. Like *S. alba*, the young shoots seem to be well adapted for coarse basket-work if properly grown for that purpose, but the rapid development and hardness of this tree may give it greater economic value than Poplar or *Eucalyptus globulus* in some parts of California.

*Salix alba* and *S. alba vitellina* come next to *S. Salmoni* in point of growth, the former rising to a height of twelve feet, the latter to nineteen feet, with trunks which girth eight or nine inches. Although both these Willows are extensively used in Europe for timber, for charcoal, for hoops and basket-work, for tanning materials and other purposes, they do not as yet appear superior to some of our best native species.

*Salix pentandra*, though less rapid in growth, seems to be worth cultivation. The largest tree stands ten feet high, with a girth of five inches. The large, dark green, smooth and glossy leaves are extremely handsome. This species yields bark that is very rich in salicin, a substitute for quinine and a useful anti-rheumatic.

*Salix caprea*, another handsome species, grows very rapidly here. The tallest trees are fourteen feet high, with trunks eight inches in girth. The bark is valuable for certain sorts of tanning and the timber is very useful.

The average rates of growth of some leading species, as compared with *Salix Salmoni*, have been as follows; age, soil, culture and other conditions were the same in all cases:

	Feet.		Feet.
<i>S. Salmoni</i> , . . . . .	30	<i>S. Sieboldii</i> , . . . . .	10
<i>S. alba vitellina</i> , . . . . .	18	<i>S. Madeni</i> , . . . . .	8
<i>S. regalis</i> , . . . . .	15	<i>S. cordata</i> , . . . . .	6
<i>S. caprea</i> , . . . . .	14	<i>S. viminalis</i> (female plant),	5
<i>S. daphnoides</i> , . . . . .	13	<i>S. lucida</i> , . . . . .	4
<i>S. viminalis</i> (male plant),	12	<i>S. purpurea</i> , . . . . .	4
<i>S. pentandra</i> , . . . . .	10	<i>S. discolor</i> , . . . . .	3

The best native Willows under similar conditions appear to rank in point of growth somewhere between *Salix Sieboldii* and *S. regalis*.

Niles, Calif.

Charles H. Shinn.

Recent Publications.

*Stories of Insect-Life.* By Clarence Moores Weed. Ginn & Company, publishers, Boston and London. 1897.

This little book, of fifty-four pages, bears no introduction or dedication, but is evidently intended for children or those taking their first steps in entomology. It is, in fact, a number of first lessons or a primer which would naturally precede the same author's more elaborate *Life Histories of American Insects*, recently noticed in these pages. The short chapters particularly deal with only a dozen of our most common insects, although their attendant parasites are also noticed. Naturally and properly the first chapter is on "The Tent Caterpillars and their Nests," something that children are most likely to observe and inquire about, and the following chapters tell of "The Moth and its Eggs" and "The Tent Caterpillar Parasite."

The descriptions for the most part are simple and apparently freed as much as possible from technical terms, although there are some points which need to be made clear to the young mind. As there are various species of various genera of tent-building caterpillars it might have been better if the name of *Clisiocampa* had been given in connection with the species under discussion. It would certainly be no more difficult to master than the word *ichneumon* which is used, and in the child's mind tent-

caterpillar might mean the Fall Web-Worm, an insect of very different habits and appearance. Other popular subjects arranged for the juvenile mind are on the Common Potato Beetle, the May Beetles or June Bugs, and Cabbage-worms. It is a question whether the Ant-lion, the Lace-wing Fly, or the work of the larva of a Syrphus fly among plant lice are sufficiently well-known subjects to treat in a book or booklet of this kind, when so many more conspicuous or cosmopolitan species are available. The history of the Dobson, although interesting, is a subject likely to be practically understood by a select few who have opportunities for observation in particular localities. In this class is most likely to be the fisherman or boy who frequents the shores of some rocky brook or river; and he may wonder why the adult Dobson should be called a "Hell-gramite," a name quite as heavy for the young mind to carry as *Clisiocampa* for the tent-caterpillar.

Each chapter, however, cannot fail to interest every true observer of animate nature who may be taking first lessons in the wide field which opens before those who enter the domain of Entomology. The pages are well illustrated by numerous original or borrowed figures and the typography is large and clear.

### Notes.

The venerable Box-trees in the Bartram Garden, in west Philadelphia, which are probably 150 years old, and now about twenty-five feet high, are still in perfect health and beauty, and show the permanency of this European and Asiatic tree in the Atlantic states, where of late years, at any rate, it has been too generally overlooked by gardeners. Every one knows the value of the dwarf Box for the edgings of garden beds, but it seems less generally known that all of the numerous arborescent forms of *Buxus sempervirens* are hardy, even in New England. There is something very homelike in the Box and its pleasant odor, even to Americans, who generally know it only in old gardens or in foreign lands, and there is no plant which we can use here safely which is such a cheerful winter inmate of northern gardens; and no other broad-leaved evergreen we can plant grows equally well in the shade of other trees and in the full light of the sun. Most beautiful when it is allowed to grow naturally into a rather open-branched small bushy tree, the Box is also well suited for formal gardening and bears wonderfully well an annual shortening of the branches, which changes the open-headed tree into a dense ball or pyramid which, once formed, can be kept indefinitely in shape.

The berries of *Cissus Ampelopsis* of the middle and southern states are most remarkable as well as beautiful in color, clear pink, purple, rich blue, and an almost emerald green occurring in the same cluster. The botanists describe them as bluish, bluish or greenish, etc. They much resemble those of the Chinese species, often cultivated in this country for its beautifully colored fruit, and are not less beautiful, but while in the latter the prevailing color is a rich Nile blue verging to emerald green, purple and pink shades, especially the latter being exceptional, the reverse is true with the American species, in which a delicate lilac-pink is the predominating hue. Like the blue berries of *Cornus circinata*, the berries of this vine, which in the forest completely covers large trees with a luxuriant drapery of foliage, are a favorite fruit of many kinds of birds, particularly the catbird, brown thrasher, wood thrush and flicker, and on this account, if no other, should be grown by all lovers of birds. The fruit of *Cissus stans*, another southern species, is also very distinct in its coloring, the extremely glossy berries, the size of peas, ranging from light pink, through garnet, red and dark crimson to jet black. The elegant pinnate foliage of this vine is unique in its peculiar dark bluish-green color, the upper surface of the leaves having a semimetallic lustre.

In this winter month vegetables are still shown in great variety not only in the principal markets, but as part of the regular stock in many of the food-supply stores in residence sections of the city. Besides summer crops grown in the north, as Irish potatoes, sweet potatoes, cabbage, celery, onions, pumpkins, Hubbard squash, carrots, parsnips, beets, salsify, celeriac, Jerusalem artichokes, Brussels sprouts, cauliflower and turnips, fresh products from hothouses and southern

fields are common. Small carrots in bunches, with fresh tops, are one of the most attractive and showy of the new vegetables; these are grown in frames near by; choice mushrooms now sell at sixty-five cents a pound; radishes, from northern hot-houses, and cucumbers, from Boston, are seen in every collection; the latter cost fifteen cents each. Cucumbers grown out-of-doors in Florida cost half this price. Scalloped squashes, or cymplings, from Florida, at seven cents each; string-beans, at twenty cents a quart; peas, at \$1.00 a half-peck, and tomatoes, at twenty cents a pound, are other receipts from the same state. Eggplants, peppers and okra are in regular supply. New beets, from New Orleans, cost seven cents a bunch, and new potatoes, from Bermuda, bring fifty cents a half-peck. Artichokes, from France, sell at twenty-five cents each. Kale, lettuce, spinach, escarole, dandelion, cress, chervil, parsley, corn salad, mint, chives and tarragon are all seen at Kelly's, in Washington Market, many of the more delicate and tender greens coming in neat bunches in small hand-baskets direct from growers in New Jersey and Long Island.

In the November issue of *The Botanical Magazine*, Sir Joseph Hooker figures and describes *Mammea Americana* (t. 7562), a West Indian tree cultivated for its edible fruit, the mammee apple, which occasionally finds its way into the fruit-stores of this city. The fruit, which Sir Joseph Hooker has eaten on the Cape de Verde Islands, where this tree was early introduced, he compares to a good turnip with a sweetish and faintly aromatic flavor. The *Mammea Americana* is a large umbrageous tree from sixty to seventy feet in height, with a stout trunk and a dense head of thick branches covered with dark brown bark. The handsome white flowers are produced singly or in from two to four flowered clusters directly from the wood of the branches in the axils of fallen leaves, and are fragrant and about an inch and a half in diameter. The fruit, which varies from that of the size of an orange to that of a child's head, is hemispherical or nearly so, with a rough, leathery yellow bitter rind and a thinner interior skin enclosing a firm, somewhat spongy white pulp soon turning yellowish and of a hard fibrous consistency. This pulp surrounds from one to four large brown oblong, rather compressed rugose nuts with hard fibrous coats and oily, fleshy cotyledons. By the Portuguese and early British residents in the West Indies the fruit was cut in pieces and eaten with wine and sugar, and also preserved. A liquor called Eau de Creole and Crème des Creoles is obtained by distillation from the flowers infused in spirits of wine. From the bark an acrid resinous gum is obtained and the cotyledons yield hair oil. The wood is described as being comparatively worthless, but the tree with its brilliant green leaves and deliciously scented flowers is so handsome an object that Tussac, in his *Flora of the Antilles*, where it is well figured, speaks of it as "*La Sirène Végétale*."

The following note by Mr. W. L. Jepson, published in the November issue of *Erythea*, will interest, perhaps, those who have been successful in cultivating *Carpenteria Californica*, one of the most beautiful flowering shrubs of the Pacific states. "The first collector of this plant, as is well known, was General Fremont, who obtained it on one of his expeditions through the interior of California. No definite locality was known for *Carpenteria* until Dr. Gustav Eisen rediscovered it in Fresno County, on Big Dry Creek, in the foot-hills north-east of Fresno City. The shrubs, of which there were probably about 1,000, grew on the southern exposure of a chaparral hill about a mile above the toll-house, near what is known as the Grape Vine Spring, on the road to Pine Ridge. The altitude is about 3,500 feet, where are found the last Digger Pines (*Pinus Sabina*) and the first Sugar Pines (*Pinus Lambertiana*); it is also the lower limit of *Fremontia*, which extends 500 feet higher up. The shrubs were about seven to eight feet in height, and the flowers very striking in their showiness. The particular hill on which the species was found was about a mile in circumference. Big Dry Creek does not empty into Kings River, but loses itself in the San Joaquin Plains. Dr. Eisen collected about twenty-five pounds of the fruit, which was sent to a Washington florist, who distributed seed to other florists of the eastern United States and Europe. From such a source came the plants that were offered for sale in their catalogues. From seed of the same collection a single plant was also grown in the experimental garden of the Department of Agriculture of the University of California. This bush has never fruited, but it has been easily propagated by cuttings. The above account of the single known locality was drawn up from a verbal description by Dr. Eisen. The rediscovery of the species was made in 1875 and the locality was revisited during several years thereafter."

Landscape-gardening.

PUBLIC attention has recently been directed in this city to several enterprises seriously affecting the future of the public parks. Among them are the creation of the Botanical Garden, the transference of the Zoological collection from Central Park to one of the newer pleasure-grounds, the proposed erection of the Soldiers' and Sailors' Memorial, and the alteration of the entrance to Central Park at Eighth Avenue and Fifty-ninth Street. In none of these cases has the best course been pursued to secure the best result. Either the advice of experts has not been asked or it has been asked and not respected.

The fact that in so many instances, happening within a short space of time, mistaken efforts have been combatted, but without full success, proves that we are awakening to the truth that expert knowledge is required for the protection of our parks, but that we do not yet really appreciate either its nature or its value. And this means that we do not yet appreciate the individuality and the importance of the art of landscape-gardening.

More interest is felt in this art, both by the public and by artists in other branches, than was felt a few years ago. Yet the old idea that any person, ignorant of art but possessing a "feeling for nature," is competent to decide any question with regard to a naturalistic pleasure-ground has not yet died out. And, on the other hand, those who are expert in artistic questions of some different kind do not yet understand that, nevertheless, they may be incompetent to deal with problems of naturalistic landscape-gardening.

This branch of the art of gardening is of much more importance to the American people than the branch which concerns itself with the creation of formal pleasure-grounds. Of course, the borders of the two branches overlap; but naturalistic ideals are those which, in the great majority of cases, can best serve the needs of American communities. Only in the narrow environment of city buildings, and in the immediate vicinity of large and stately edifices which stand in more open situations, are formal gardening schemes demanded in this land and age. Vast formal pleasure-grounds, such as were created around the palaces of the Old World for the delectation of the frequenters of luxurious courts, are inappropriate to the needs of modern

times; and this is especially true in our democratic country. Our parks, large and small, exist for the greatest good of the greatest number; and this good can best be secured by making them, within the bounds laid down by art, as much like Nature's landscapes as possible. Only in this way can they fulfill the need of the populace for rest and refreshment, and bring Nature's peaceful, soothing, inspiring influences to bear upon the minds and bodies of those who live and toil amid the noise and stress of modern civic conditions; and only thus can they be genuine and characteristic works of American art, expressing the ideals and the temper of American civilization. The question of relative beauty need not be discussed. It need not be inquired which is more beautiful in itself, a great formal rich man's pleasure-ground like the royal park at Versailles or a great popular pleasure-ground like Prospect Park in Brooklyn, for it is certain that a popular pleasure-ground is the one which American tastes and practical needs require.

Probably no one will deny these assertions. The disputes which constantly arise in respect to our parks spring merely from disagreements in regard to what bounds art lays down for their treatment. But here the divergence is wide. The average citizen seems to think that, as a public park is for the public good, anything and everything which any section of the public desires ought to be provided within its borders. The average "lover of Nature" believes that Nature herself has set the bounds and prescribed the scheme for its beauty; that the artist should blindly respect everything she has created on the given site or, introducing needful work of his own, should make it as deceptively natural-looking as possible; and that, once his park is ready for use, Nature alone should care for its vegetation; and the average architect believes that a naturalistic park is a concession to the taste, or lack of taste, of our inartistic time; that it should, therefore, be made as little naturalistic as possible; that it should contain as many formal passages and ornamental structures as can be compassed, and that these should be considered of primary importance.

But widely apart as these extremists stand, their misconceptions are based upon the same error. Neither of them perceives that naturalistic gardening is in itself a true and noble art, an independent art, with special ideals and laws and boundary lines which cannot be well understood except by those who have given them special and sympathetic study.

In these pages an effort has more than once been made to explain, as well as brief words could do it, the aims and expedients of this branch of gardening-art, which was born, at the close of the Renaissance period, with the birth of modern civilization, and has perhaps received its fullest and finest expression in this country. Such an effort cannot be repeated now. To-day we merely wish once more to call attention to the dignity, the individuality and the essentially American character of the art of landscape-gardening, and to warn our people once more not to allow themselves to forget the need of experts to guard as well as to create their parks, and not to mistake the meaning of the word expert. A man is not necessarily an expert in park matters if he accepts the office of park commissioner, or if he is a practiced botanist or horticulturist or engineer, or if he is a passionate lover of Nature, or if he has taste and experience in artistic works of other kinds. He is an expert in park matters only if, with inborn artistic taste and an understanding of the needs of our people to help him, he has thoroughly studied landscape gardening itself and its application to American conditions. The engineer may have a portion of the needful wisdom, and so may the architect, the botanist, the horticulturist, and the business man familiar with large financial undertakings. But not either one of them nor all of them together can have the power to design a naturalistic pleasure-ground well or to maintain it properly.

Different dangers have threatened American parks at different times; just now in this city, at least, they seem to be specially threatened by the danger that the architect

will confidently assert his ability to design and to conserve them, and that the public will endorse his claim, believing him to be an expert. In one sense his art stands closer to that of the landscape-gardener than any other. Both concern themselves with the production, not of merely ornamental objects, but of objects of practical utility destined for actual occupation or frequentation by human beings; and the work of laying out formal gardens has a close æsthetic as well as practical affinity with architectural work. But here the parallel ends. Naturalistic gardening has very little æsthetic affinity with architecture. Symmetry and definite balance, mathematically exact proportioning, unity achieved by the repetition of conspicuous forms and features, and harmony achieved by the reiteration of subordinate ornamental motives—these are merits so characteristic of the art of architecture that, whenever we see them achieved in other arts, we say that the result has an architectural kind of beauty. But they are not the merits for which the landscape-gardener strives. He strives, indeed, for unity and harmony, for balance of parts and for appropriateness in the use of ornamental details; but he achieves them by avoiding symmetry and obvious repetitions, by appearing to treat each passage in his work for the sake of its individual importance and yet by combining them in subtle ways, often inexplicable in words, into a coherent artistic whole. The student of Oriental art will get a glimpse of his ideals when we recall the fact that the Chinese were the earliest landscape-gardeners, and say that, as modern architecture—with its helper, formal gardening—has come down to us in a straight line from classic art, so landscape-gardening has come down to us in a straight line from early Oriental art. It is not now in America the same art that it was in ancient China, any more than our buildings are the same as those which the Egyptians, Greeks and Romans knew. But the general ideal has been preserved in the one case as in the other. The radical difference between the ideals of the architect and of the landscape-gardener therefore lies in the fact that the one secures unity, harmony and beauty by the use of symmetry, the other by its avoidance.

This is the great reason why the modern architect, unless he has also made a special and sympathetic study of landscape-gardening, should not pose as an expert in park matters. The better architect he is, the less likely he is to understand the aims of an art so radically unlike his own in its ideals, or even to confess that it is as true and worthy an art as his own. Other things being equal, a landscape-painter is much more likely to understand the beauty and therefore to realize the needs of a naturalistic park than an architect. He knows that a natural landscape is not always beautiful, but often needs to be "arranged" before it can be turned into a picture; and he knows that this may be done without injury to its naturalistic character. He understands how composition—meaning a beautiful harmonious arrangement of lines and colors, of masses and voids, of lights and shadows—may be achieved without symmetry; he knows how balance may be secured without an obvious opposition of equal parts, how details may be made truly ornamental without reiteration, and how all this may be done in accordance with binding artistic laws and yet the general result seem spontaneous and natural.

Of course, on the other hand, the landscape-painter cannot be expected to understand those practical problems which, in the making of large parks, are of equal importance with æsthetic problems. He is not an engineer, he is not a horticulturist, and he is not experienced in regard to the needs and habits of masses of people seeking refreshment in the open air. Thus we come back to our main proposition: No one is experienced in all these matters except the man who has studied the making of naturalistic parks in and for itself. There are not many such men in our country. There are some, however, and they alone have the right to be regarded as experts. And until the public on the one hand and the artistic professions on the

other recognize this fact and act in accordance with it, our parks will never for a day be really safe from educated or ignorant vandalism.

#### Notes on Cultivated Conifers.—XII.

**C**EDRUS, which is confined to the Atlas Mountains of Algeria, the Island of Cyprus, the Lebanon, the Cilician Taurus, and to the mountains of northern India and southern Thibet, is a well-marked genus of three species, with scattered primary and tufted secondary persistent leaves, solitary staminate flowers on the ends of short spur-like branches, and erect cones with thin, entire, rounded, persistent scales. The type of the genus, *Cedrus Libani*, is one of the most magnificent of all cultivated conifers in those regions like some parts of England and France, where it really flourishes. The Cedar of Lebanon is not hardy, however, in Massachusetts; it barely survives in the neighborhood of New York, although a few years ago there was a fairly good specimen on the grounds of the old Prince Nursery, on Long Island; it is more successful further south and there are a number of healthy plants near Philadelphia and Washington. On the whole, the Cedar of Lebanon must be considered a failure in eastern North America. All the cultivated plants, however, are derived from seeds raised in Europe on trees taken from the original Lebanon stock, and it is quite possible that if plants were raised from seeds obtained from the high Cilician Taurus, a more northern and a colder region than the Lebanon, they would prove as hardy here as the Cilician Fir, another conifer of the same region. This would be an interesting and useful experiment to make, but, unfortunately, it appears practically impossible to find any one in the central part of Asia Minor to gather the seeds. The Algerian Cedar (*Cedrus Atlantica*) is rather more hardy than its near relative of the Lebanon, and small plants of the beautiful blue-leaved form of this tree have lived for the last two or three years in Mr. Hunnewell's pinetum. It is more vigorous, however, further south, and the best plants of this form which I have seen in the eastern states are at Biltmore, North Carolina. The Himalayan Cedar (*Cedrus Deodara*) has not proved a successful tree in Europe, where it has been planted in large numbers; it is not at all hardy here at the north, but I have seen healthy plants in Georgia and other southern states, and in California.

*Larix*, the Larch, is closely related to *Cedrus*, but the leaves are deciduous; the male flowers are borne on lateral branches of the previous year, and the much smaller cones with scales shorter than the bracts in some species, are at first nearly horizontal, and then assurgent. The genus, which is widely distributed over the boreal and elevated regions of the two hemispheres, is composed of about seven species, which are generally large trees and produce strong, durable and very valuable timber.

The Larch which has been most planted in the eastern states is *Larix Larix*, the Larch-tree of the mountains of central Europe, where it sometimes grows in extensive forests, and frequently forms the timber-line either alone or with the Spruce and Stone Pine. This Larch has been largely planted in Europe for timber, especially in Scotland, and successful experiments have been made with it as a timber-tree in New England. It is very hardy here and grows rapidly even in dry gravels, but, like the native species, it is now frequently disfigured by insects which kill the leaves during the early summer and weaken the trees, although they usually cover themselves with a second crop of leaves. In very early spring the Larch is lovely with the tender green of its young foliage, but later in the season the leaves often have a rusty look, due perhaps to the heat and dryness of our summers; and this Larch, which seems to belong only on rough mountain sides, appears, with its small regular branches and straight pyramidal habit, out of harmony with round-headed trees and out of place in pastoral landscapes. There is a form of *Larix Larix* with distinctly pendulous branches (var. *pendula*) of Swiss origin,

and now common in cultivation, which is curious rather than handsome; and Beissner describes other abnormal forms which I have not, however, seen. The Siberian Larch (var. *Sibirica*) is now generally considered a geographical form of the European species. It forms great forests on the plains of Russia and Siberia, and grows also on the Ural and Altai Mountains. This tree, so far as I know, has not been sufficiently tested in the United States.

Much more picturesque than the European species is our native *Larix laricina*. This inhabitant of northern swamps grows to a large size when transplanted into dry ground, and sends out long and often contorted branches. It is this tree which may often be seen in great beauty standing near old New England farmhouses and country mansions, and as an ornamental tree the eastern American Larch, which has been neglected in recent years, may well be used much more freely than it has been.

In *Larix occidentalis* of the high interior Columbian basin of the north-west *Larix* displays its greatest size and nobility of port, and furnishes to the world one of its great trees. From 150 to 200 feet in height, with a tall massive trunk from seven to ten feet in diameter and covered with bright cinnamon-red bark broken into thick enormous plates, the western Larch is one of the most beautiful and impressive trees of the continent, and in strength of timber surpasses all other American conifers.

Long neglected by the cultivators of exotic trees because David Douglas, who introduced most of the trees of the north-western part of this continent into English gardens, mistook it for the eastern species, *Larix occidentalis* was first cultivated in 1880 in the Arnold Arboretum, whence it has been distributed among many of the principal tree-lovers of the United States and Europe. Seedling plants of this Larch grow badly here and still remain small and stunted, but grafted on the roots of the Japanese species it has grown rapidly and vigorously, and the largest plants, now about eighteen feet in height, have already produced a few cones. The second species of western North America, *Larix Lyallii*, is a small alpine tree found only at the timber-line on some of the high mountains of southern Alberta and the adjacent parts of the United States. It has not been introduced into cultivation, and probably would grow very slowly at the sea-level. Even in its best condition, this Larch has little to recommend it to the lovers of ornamental trees.

The Japanese Larch (*Larix leptolepis*) is common at elevations of from 5,000 to 6,000 feet above the sea, scattered always in small groves mixed with other deciduous trees, and is confined to the central part of the main island. It is a handsome tree, seventy or eighty feet tall, with pale blue-green foliage and a massive trunk covered with reddish bark, and in habit is not unlike the European species. *Larix leptolepis* is perfectly hardy in eastern Massachusetts, and the large specimen which stood for nearly thirty years in Mr. Hunnewell's pinetum produced annually abundant crops of fertile seeds. Although it grows here very rapidly, the Japanese Larch is certainly inferior as an ornamental tree to the native species, and it probably will never become popular in this country. There is an alpine form of this tree (var. *Murrayana* of Maximowicz—*Larix Japonica*, Murray) which grows on Fugi-san at an elevation of about 8,500 feet, and differs from the common form only in its dwarfer habit, shorter branches and smaller cones. This plant has been raised in the Arnold Arboretum from seeds which I brought from Japan five years ago. It is, of course, too soon to form any idea of its value here. And this is true of *Larix Dahurica*, which is a large tree not unlike the European Larch, and possibly only a geographical form of that species, which is widely distributed through Siberia, northern China, Manchuria, Kamtschatka and Saghalin. Young plants of this Larch are growing well in the Arboretum, where they give promise of success, as do seedlings of the form of this species which reaches the extreme northern part of Yezo and the Kurile Islands (var. *Japonica*

of Maximowicz—*Larix Kurilensis* of Mayr) (see GARDEN AND FOREST, vol. vi., fig. 76).

The Himalayan *Larix Griffithii* has been raised several times in the Arboretum, but the seedlings have soon died, and I have never seen anywhere a good plant of this Larch, which in its native mountain forests of Nepal, Sikkim and Bootan is a slender tree sixty or seventy feet in height with long thin pendulous branches and elongated cones larger than those produced by any other Larch-tree, and conspicuous for their long exserted bracts.

*Pseudolarix*, like Ginkgo, is a monotypic Chinese genus known only from trees cultivated in temple gardens. It resembles *Larix* in its clustered deciduous leaves, but differs from that genus in its stalked, elongated, pendulous male flowers, borne in umbels at the ends of short spur-like lateral branchlets, and in its deciduous cone-scales, which separate from the central axis as soon as the cone ripens. Little is really known yet of this interesting tree either in Europe or America. Fortune, who first saw it dwarfed in Chinese gardens, finally, in 1854, discovered some trees near a Buddhist monastery in Che-kiang, which he estimated to be from 120 to 130 feet in height with trunks five feet in diameter, and sent the seeds to England. If it is cultivated at all in Japan I failed to notice it there, and Rein in his exhaustive work on that empire does not mention *Pseudolarix*, so that this tree is known outside of China only from specimens less than fifty years old. The largest tree I have seen is in the Rovelli Nursery at Pallanza, Italy, and is now probably nearly forty feet high; on the grounds of the old Parsons Nursery in Flushing, Long Island, there is a plant nearly as large, and in Mr. Hunnewell's pinetum there is one that has produced fertile seeds for several years. *Pseudolarix Kämpferi*, as the species is called, appears to delight in hot dry summers, and will probably succeed in our northern states better than in western Europe. I have never seen a plant which appeared to suffer from heat or cold, fungal diseases or the attacks of insects. The Golden Larch, so named probably because the leaves turn bright clear yellow in the autumn before falling, is one of the most promising of the exotic trees which are on trial in this country, and now that plants in Europe and America are beginning to produce seeds, it will soon be possible to test it here more thoroughly than it has been in the past. The young trees have more the habit of *Cedrus* than of *Larix*, with long branches usually pendant at the extremities, and generally a broad flat-topped rather than a pyramidal head.

*Pseudotsuga*, a barbarous and entirely inappropriate name, half Greek and half Japanese, has been inflicted on one of the most beautiful and valuable of all American conifers, the great Douglas Spruce of western North America. The genus is pretty closely related to *Abies*, from which it differs, however, in its petioled leaves, pendulous cones with persistent scales always much shorter than their conspicuous three-lobed bracts, and in the structure of the seeds, which are destitute of resin vesicles. There are two species in western North America, and in Japan, judging from the figure of a cone recently published in a Japanese botanical periodical, there is evidently a third about which, however, nothing as yet appears to be known to the outside world.

The Douglas Spruce, *Pseudotsuga taxifolia*, is one of the largest and most widely distributed trees of the continent. Near the shores of Puget Sound, where it grows in the greatest perfection, individuals between three and four hundred feet in height, with trunks ten feet in diameter, are not rare, and trunks even larger can occasionally be found. Trees nearly as large grow on the western slope of the California Sierra, but in drier interior regions where the Douglas Spruce is found on nearly all mountain ranges southward to Mexico and eastward to Wyoming, the outer range of the Rocky Mountains in Colorado and to the mountains of western Texas, it is a smaller tree, usually not more than 100 feet in height, with a trunk only four or five feet in diameter. The Douglas Spruce was introduced into English gardens nearly seventy years ago by David Douglas, and its value as an ornamental tree in

western Europe is shown by the existence there of specimens already more than 100 feet high, with long lower branches sweeping the ground. The first attempt to cultivate this tree in the eastern states with plants, doubtless of Oregon or California origin, imported from England, were not successful, as they were generally unable to adapt themselves to our dry, hot summers. But in 1861 Dr. C. C. Parry found the Douglas Spruce in Colorado, and from the seeds which he sent to the Harvard Botanic Garden plants were raised which have proved perfectly hardy here. The largest of these are now more than twenty-five feet high, densely clothed to the ground with vigorous branches, and perfect in color and density of foliage.

This demonstration of a fact that plants of the same species, raised from seeds gathered in different parts of a wide territory with different climatic conditions, is interesting, as it indicates that it may be possible to cultivate other trees here which have heretofore been considered tender, if specially selected seeds are used. In the case of the Douglas Spruce several American nurserymen have not been slow to take the hint, and during the last ten or fifteen years great numbers of the Colorado form have been planted in New England, where the plants are growing rapidly into handsome, healthy trees, promising, if it is safe to judge by the appearance of this tree in its native forests and in Europe, to surpass here in permanence and mature beauty the other conifers of western America.

The second American species of *Pseudotsuga* (*P. macrocarpa*) is a small tree found only on the arid mountains of southern California, which has never been tested here and could never support the cold of a northern winter.

The next and final number of these notes will be devoted to *Abies*, the only remaining genus of *Coniferæ* which furnishes hardy plants to our northern gardens.

C. S. S.

#### *Lilium parvum* and *L. parviflorum*.

IN his *Synopsis of all the known Lilies*, published in 1875, which is still the best authority for the nomenclature of this noble genus, Mr. Baker treats *Lilium parvum*, *L. Walterii* and *L. parviflorum* as varieties of *L. Canadense*. In the *Botany of California*, published in 1880, Dr. Watson follows Dr. Kellogg, who first described *L. parvum*, considering it a distinct species, and accurately describes Kellogg's typical form, but assigns to it a far more extensive range than it really possesses. Dr. Watson quite overlooked the other forms. At a still later date some English authority gave the name of *L. pardalinum*, var. *minor*, to one of the forms of *L. parviflorum*, which is now quite generally known in European gardens under that name.

I believe that a much more natural grouping would be to confine the name *Lilium parvum* to Kellogg's typical form, and to include all of those forms with more or less reflexed or revolute flowers under *L. parviflorum*. Following this division, therefore, I will proceed to speak of the typical *L. parvum* of Dr. Kellogg, the *L. Canadense*, var. *parvum*, of Baker.

*Lilium parvum* is a lily of high and subalpine regions in the central portion of the California Sierras. So much of the Sierra Nevada is unexplored by botanists that it is hard to set close bounds to the range of a species, but I have good evidence that the species does not extend to Plumas County on the north or farther than the Yosemite Valley on the south. It is found at an altitude of from six to nine thousand feet, and is common along the snow-fed streams which flow into the Truckee and Lake Tahoe on the east, and into the Yuba and American rivers on the west, as well as about the edges of the Tamarack swamps of that elevated region. It is not infrequent at an altitude where the snow lingers until July and August, and is again seen in September or October.

*Lilium parvum* is a charming little lily, well worthy of general cultivation. The soil in the localities where it is found is a granite sand rich in vegetable matter and the drainage

is good. It can hardly be called a Bog Lily. The stems are slender and leafy, and both stems and leaves are light green. The leaves are from long ovate to broadly lanceolate. There are a few whorls, but many leaves are scattering. The flowers are horizontal or ascending, funnel-formed, with only the tips spreading and a brilliant orange-red in color, dotted with maroon, with the tips a brighter red. They are from an inch and a quarter to an inch and three-quarters long. The size of the plants varies greatly. About the swamps they are often from one to two feet high and few-flowered, but along the banks of streams plants from three to five feet high and many-flowered are common. The bulbs of *L. parvum* are very small. Selected bulbs will not average above one-fifth of an ounce in weight, and measure an inch and a half in length by half an inch in width. They are rhizomatous, and thickly covered by three or four jointed scales which produce a beautifully-laced effect. They do not have runners like *L. Canadense*, nor do they ever branch and form mat-like clumps as is the habit of *L. pardalinum*. Not one bulb in 500 is branching or produces two stalks. Some years ago this Lily was distributed by Messrs. Hallock & Son, Queens, New York, under the name of *L. pardalinum*, var. *alpinum*.

In bulb, leaf and capsule *Lilium parviflorum* resembles *L. parvum*, but is stouter and larger, as a rule. In size the bulbs sometimes approach those of *L. pardalinum* in size, but the four-jointed scales and lace-like effects are constant features, and the bulbs seldom branch and never form the matted clumps so distinctive of the latter species. The stems may be very stout and tall, but the broader leaves, paler foliage and rounder, shorter capsule sufficiently distinguish it. There are many forms prevailing over more or less extensive regions. In some forms the flowers are as revolute as those of *L. pardalinum*, but they are smaller and fragrant, and this species comes into bloom several weeks before *L. pardalinum*. Mr. Baker says that *L. parviflorum* bears its flowers in an umbel, and I do not question the correctness of the statement as regards his specimen. Several Californian Lilies carry their flowers in umbels when there are few, and in racemes when there are many. Mr. Baker describes *L. rubescens* as umbellate, but it is only so when few-flowered.

The commonest form of *Lilium parviflorum* is the one distributed as *L. pardalinum*, var. *minor*, by some dealers, and still more widely sold as *L. parvum*. It has a flower like a small reddish orange *L. pardalinum*, and is found in the middle belt of the Sierra Nevada from Tulare County, in the south, to the base of Mount Shasta. Plants grown from bulbs collected at different points along this line are hardly distinguishable, and plants from Crater Lake, Oregon, seem identical. There is no reason to doubt that *L. parviflorum* in some of its forms extends into British Columbia, as mentioned in Baker's *Synopsis*.

On the Sierras, in Plumas County, especially on Lassen's Butte, *Lilium parviflorum* has subalpine forms which are indistinguishable from the typical *L. parvum* except that the flowers are tardily reflexed from the middle. For several days they are apt to remain broadly campanulate. In the same region the form is found described by me in *Erythea* in October of this year as *L. parvum*, var. *luteum*, which, by the division of *L. parvum* that I now propose, would become *L. parviflorum*, var. *luteum*. This very handsome little Lily is like *L. parvum* in every particular excepting that the small revolute flowers are a clear orange-red, brightly dotted with scarlet.

I might mention that a clear orange form of the true *Lilium parvum* has been figured in Europe as *L. parvum*, var. *luteum*. It has funnel-formed flowers. The *L. Canadense*, var. *Walkerii*, of Baker's *Synopsis*, I have never seen, and there are doubtless many other transitional forms belonging to this group, but *L. parvum* and the type of *L. parviflorum* are practically all which have been cultivated thus far.

## New or Little-known Plants.

*Prunus Davidiana*.

Numerous references have been made in the columns of this journal to the beauty of *Prunus Davidiana* as a flowering plant. It is a small bushy tree, discovered

the tree and its flower-buds are very hardy, the flowers are occasionally killed by late frosts. *Prunus Davidiana* has fruited in Paris, and more freely in the south of France, but in this country it has not, so far as we have heard, produced any of its small thin-fleshed fruits, which have no comestible value. The pale pink and white flowers, however, are lovely enough to compensate for the want of fruit

Fig. 64.—*Prunus Davidiana*.

about thirty years ago by the Abbé David, who found it in the neighborhood of Pekin and also near Gehol, the summer residence of the Emperor of China. Botanically interesting as being somewhat intermediate in character between the Peach and the Plum, *Prunus Davidiana* is the earliest of all the Peach-like trees to flower in this climate, and, although

and make this one of the most desirable of small early-flowering trees.

Our illustration on this page, made from a photograph for which we are indebted to Mr. James M. Codman, of Brookline, Massachusetts, shows a bunch of flowering branches of this tree from the Arnold Arboretum.

## Calopogon pulchellus.

SOME years ago one of the illustrated journals gave a sketch, with this legend: First tourist, "And how do you like Venice?" Second tourist, very bewildered, "Venice! why, is this Venice? I thought it was Milan; the itinerary says we are to be in Milan to-day." This is the typical state of mind of plant collectors who try to fit their newly-found plants to the descriptions found in either scientific manuals or popular hand-books. The description is grasped with a tenacity worthy of a better cause, while the charm of variation is quite lost sight of; consequently, when plants varying even slightly from the accepted description are found they are looked upon as something rare or unique.

The common descriptions of *Calopogon* usually read as follows: "Plant about one foot high, bearing from two to six flowers; color, magenta." *The Dictionary of Gardening* is even more modest and reduces the number of blossoms from "two to three," based on the plants figured in *The Botanical Magazine* of 1790\*, which were the first specimens seen in England. Mr. Baldwin alone seems to really have seen *Calopogons* as they are commonly found, and in the *Orchids of New England* gives from three to nine blossoms as the ordinary number.

In the bogs of Adams and Franklin Counties, Pennsylvania, where they are very numerous, the plants vary from ten to twenty inches in height, and bear from six to fifteen flowers, eleven being an average number during midseason, both early and late ones having fewer blossoms. The season is longer than that of any other native Orchid, except the inconspicuous *Spiranthes*, and lasts from late in June until about the beginning of August.

The plants figured on page 505 were gathered late in June and represent the most ordinary specimens found by the hundreds in the South Mountain meadows. The coloration is generally given as "magenta," which seems to me too harsh a term, as they are only magenta when removed from their setting of bog-moss and grasses. The sepals and petals are usually of the same tone throughout, occasionally the wings are lighter, and generally the ridges of the labellum are white in their lower portion.

In a small area selected for daily observation, the plants ranged from one having pure white blossoms, with light green stigmatic surface and anther-lid, through very pale pink, to those with ordinary deep pink tones. The latter in almost every instance bore many more flowers than the paler specimens, the white one having only three blossoms, though these were of unusually large size. The deep-toned specimens averaged half as many filled seed-pods as there were blossoms; in no plant that was observed were all the seed-pods developed, and in no case at all of the white or very pale specimens were any seed-pods filled, or the pollinia even removed, so the attraction for insects appears to depend not only on the kind of color, but the degree, those having a purplish tone bearing more seed-pods. This agrees with the accepted theories of color, but other localities may show different results.

The *Calopogons* bear transplantation, and were not only grown in England a century ago, but are among the American Orchids mentioned by Mr. Meehan as having been successfully cultivated by the Comte de Paris (see page 484 of this volume of *GARDEN AND FOREST*). They are not among our most showy bog-plants, but they are certainly very pretty, with a certain distinction that entitles them to consideration as worthy of protection, for the meadows where they grow naturally are more and more disturbed by the plow, so that in a few years we shall look in vain for a single plant, where now hundreds may be found. This has happened with many of our wild animals which have been hunted to extermination, and is happening to more of our wild flowers than most persons realize. Unless those interested in the preservation of our native plants endeavor, as wild land is needed for cultivation, to transfer

to protected places some of our woodland and meadow beauties, we shall in a little time find them only in the botanical gardens of large cities.

Harrisburg, Penn.

M. L. Dock.

## Correspondence.

## An Amateur's Experiment.

To the Editor of *GARDEN AND FOREST*:

Sir,—The articles entitled "Harmony in Country Places," "Native Plants for Ornamental Planting," and "What Can be Done in Nine Years," in recent numbers of *GARDEN AND FOREST*, have reminded me in so many things of my own experience in endeavoring to carry out my plans for a suburban home, that I think some of your readers may be interested in a brief account of the results of seven years of experiment, and the methods by which comparatively satisfactory results have at last been reached. The term experiment should, in this case, be emphasized, since the undertaking was not only such at the beginning, but continues so.

Besides lack of previous experience in such matters there was much to contend with in the situation and other local conditions. The grounds slope rather steeply to the south, more gently to the west, and the terraces and banks face in the same directions, thus exposing the greater part of the surface to the summer's sun; besides, the ground being a very hard clay, overlaid by a few inches of excessively poor soil, or in places none at all, a far greater amount of rain or use of the hose is necessary than on a level or more friable surface. This disadvantage proved so serious that my choicest trees and shrubs were killed by drought during the five years when they were dependent entirely upon rain and water carried by hand, and each summer, after the middle of July, it was impossible to prevent the grass from burning to the roots on those portions of the lawn and terraces not protected by shade. Now, however, having Potomac water and some eighty feet of hose, nothing has been lost from drought within the last two years, and the lawn continues green until seared by freezing weather.

It should be mentioned that my place is a small one, only 150 feet square (appropriately half an acre in area), fronting for that distance on two streets, which form the west and south boundaries, the latter marking the lowest level of the plot. Crossing the lower portion diagonally a military road had been built during the war, leading to a fort which crowned one of the neighboring knolls. The grading of this road produced the only level ground on the premises, and likewise a bank averaging about three feet in height along the upper edge. The only fair-sized trees on the place grew upon this old road and below it, some dozen or fifteen slender and rather tall Scrub Pines (*Pinus Virginiana*), about forty to fifty feet high. Ranged along the top of the bank were four fine bushes of *Cornus circinata*, several young flowering Dogwood-trees, occasional clumps of smooth Sumach, a few other shrubs and young trees, a slender Persimmon-tree growing between two of the latter Pines and nearly of the same height, and a tangle of Greenbrier (*Smilax rotundifolia*) which overran a portion of the shrubbery and clambered into the lower branches of the Persimmon. From this fringe of shrubbery and small trees the slope leading to the upper limits of the place was covered with a jungle of young Scrub Pines, intermixed with Blackberry brambles, Sumachs (*Rhus glabra* and *R. copallina*), Sassafras sprouts, weeds and coarse grasses, and a few small Red Cedars.

The first step toward improvement consisted in the building of the fence, a procedure hastened by the discovery that my larger Pine-trees had been blazed, and a fine Cedar cut down by a small boy of the neighborhood, who had become the proud possessor of a new, and evidently sharp, hatchet. The fence consisted of Cedar posts set three feet deep and connected by wire netting four feet wide.\* The glaring scars on the Pine-trees were coated with liquid grafting wax and have quite grown over. Soon after the fence was built roots of Japanese Honeysuckle were dug up from a piece of sandy ground in the neighborhood, where this hardy and beautiful climber had taken complete possession,† and planted on the inside, one at each post and one or more at the middle of each panel. These roots have developed, with assistance in the way of training and pruning, into a hedge which I believe cannot be surpassed in beauty, compactness and durability, and is far superior, in my estimation, to any hedge of shrubs which

\* The height of the fence was afterward reduced to three feet by cutting off both posts and wire at the top, and the wooden top rails (2 x 4 scantling), which were continually sagging and rotting in the middle, replaced by double wire cable, which, besides being permanent, binds the posts together far more firmly.

† This plant is abundantly naturalized in the vicinity of Washington.

can be successfully grown in this climate, being entirely unbroken, quite evergreen, and deliciously fragrant when allowed to bloom.

terest to me of native plants as subjects of study and from past associations, the necessity of placing a definite limit to my selections, and last, but by no means least, a desire to show

Fig. 65.—*Calopogon pulchellus*.—See page 504.

It was my original plan to grow only native plants. This somewhat risky departure from prevalent custom was prompted by several considerations, chief of which were the greater in-

others how beautiful our native trees, shrubs and vines really are in cultivation. I was much disappointed that a suitable native woody climber could not be found with which

to cover the fence; but as one was desired which could be pruned closely into a formal compact hedge, none appeared to meet the requirements, at least among those whose hardiness in this climate was not more or less doubtful.\* A careful examination of the woody growth upon my lot revealed the presence of a very respectable nucleus for the collection which I proposed to make, the specimens marked for preservation numbering nearly two dozen species. Most of the trees were seedlings or of but a few years' growth, while none were more than thirty years old, the largest—the tall Scrub Pines before mentioned—having grown from a road constructed and used during the war. Adjacent unimproved grounds yielded about fifteen additional species, so that I had already at hand sixteen species of trees, eleven of shrubs and nine of woody climbers before recourse was had to the nurseryman.

With the exception of one *Gordonia Altamaha* and one *Catalpa speciosa*, nothing was purchased for the collection until the autumn of 1891, when a considerable number of species not obtainable in the neighborhood were planted; additions have been made each year, until there are now established on the place more than 130 woody plants which are native to the country east of the Mississippi River and south of the latitude of New York. Of these forty-eight are trees, fifty-seven shrubs and twenty-seven woody climbers. The number of herbaceous species is unknown to me, but these embrace many of the more interesting or beautiful kinds, as *Lilium superbum* and *L. Grayi*, *Trillium grandiflorum* and *T. sessile*, several Irises and Orchids, including *Goodyera pubescens* and the rare *Tipularia discolor*, here locally common; Lilies of-the-valley, from the mountains of North Carolina; Anemones, Buttercups, Violets, including the beautiful *Viola pedata*; several Erythroniums, *Aquilegia Canadensis*, *Dodecatheon Meadia*, *Dicentra eximia*, and many Ferns. Among the larger species the scarlet Hibiscus (*H. coccineus*), perfectly hardy here, is most conspicuous.

The number of species of trees may seem entirely disproportioned to the area over which they are distributed, but with very few exceptions the kinds selected do not attain a large size, trees of small growth, as Hawthorns (four species), flowering Crab, Flowering Dogwood, Hercules Club, etc., prevailing; hence it will be many years, if ever, before serious overcrowding becomes evident; and by judicious arrangement ample space for lawn and continuous vistas are not lacking. The shrubs are, of course, grouped or massed, and, therefore, do not take up nearly the amount of room that might be supposed. The vines, being supported by the trees, do not require extra space, all the larger trees being utilized for this purpose. The naturally bare trunks of the tall Pines are densely covered with the evergreen foliage of the Cross-vine (*Bignonia capreolata*), whose profusion of yellow and dark crimson flowers, hanging in wreaths and festoons, in early May glow brightly against their dark background. The same elegant climber clothes two good-sized Catalpas (*C. speciosa*) with its golden blossoms before the leaves of the trees are large enough to hide them, the great white panicles of the Catalpa appearing ten days to two weeks after the *Bignonia* has done blooming. Two rather short and wide-spread Pine-trees growing close together support not only the *Bignonia*, but also a *Clematis Virginiana*, which reaches to the topmost twigs. Other trees, chiefly Pines, are decorated with vines of the Trumpet-flower (two species or varieties), *Wistaria frutescens*, *Celastrus scandens*, Supple-jack (*Berchemia volubilis*), climbing *Hydrangea* (*Decumarea barbara*), *Ampelopsis cordata* and *Virginia Creeper*. In fact, climbers, both woody and herbaceous, have been used as freely as possible, not only on trees, but also on the veranda and on fences, and my chief regret is that suitable supports cannot be found for more of them.

Among the shrubs all the native wild Roses are represented, including the Cherokee Rose (here quite hardy and evergreen), trained over a rustic gateway, and several scendent clumps of the beautiful Prairie Rose, to my taste the most exquisite of all single Roses. All the Azaleas are likewise established, as well as *Rhododendron Catawbiense* and the *Rhodora*; but among them all there is no more charming shrub than *Chionanthus Virginica*, with its fragrant, lace-like flowers, or the graceful, wand-like *Neviusia Alabamensis*.

Unquestionably the finest trees in my collection are the even dozen Flowering Dogwoods (*Cornus florida*), all of which, with one exception, grew naturally from seed on the premises.

\* Possibly the Carolina Jessamine (*Gelsemium sempervirens*), which has thus far proved hardy on my place, might answer, although its small narrow leaves are against the probability that it would prove satisfactory even if it would stand severe pruning. To those who prefer a vine-covered fence to a hedge of the usual kind the matter is well worth experiment, and I would suggest not only the above-named climber, but also several of the Green-briers, especially the evergreen and lower-growing species. *Bignonia capreolata* will not answer, its growth being too rampant, the same being true of the *Virginia Creeper*.

It is the only tree that has been duplicated except *Catalpa speciosa* and *Aralia spinosa* (of which three and two, respectively, have been allowed), and I would far rather materially reduce the number of species than sacrifice one of my Dogwoods. Having plenty of room, they have grown into wide-spreading symmetrical trees, and in early spring are masses of white bloom, one tree having flowers averaging nearly four inches across. The only Dogwood-tree not grown on the place is one of the pink-flowered variety, obtained from Meehan. This has proved to be all that has been claimed for this variety. Among other trees for which space has been found is the American Smoke-tree (*Cotinus Americanus*), much inferior in bloom to the European species, but equaled by no other tree of my acquaintance in the brilliancy of its autumnal coloring, its large oval leaves turning bright scarlet and orange. The Hercules Club (*Aralia spinosa*) is one of the prizes of my collection; it is decidedly more beautiful, both in habit, foliage and flower, than the Chinese form, yet not a single specimen can be found in the parks of Washington, where its foreign relative has been considered worthy of a place. Our *Aralia* is, with the exception of *Catalpa speciosa* and perhaps two or three of the *Magnolias*, the most tropical-looking of all our trees, and is of exceedingly rapid growth.

Among the discouraging disappointments and various backsets which have attended my horticultural efforts may be mentioned the loss by drought of all my *Andromedas*, *Kalmias*, *Rhododendrons*, *Stuartias*, *Gordonia Altamaha*, *Hydrangea quercifolia* and many other of my choicest shrubs and young trees; the yearly blighting and disfigurement of the coral Honeysuckles by aphides and defoliation of wild *Clematis* by bugs; the ruin of the *Robinias*, especially the two arborescent species, by borers, while borers of another kind have destroyed, one by one, about half of the large Pine-trees; the stems of *Euonymuses* and *Celastrus* are encrusted with bark lice, just as they have attained a luxuriant growth, and they probably will have to be cut down and burnt; the larvæ of June-bugs have made havoc with the lawn, while the beetles themselves have mutilated the foliage of the young Oaks; rose-beetles last May utterly destroyed the unusually abundant blossoms of several large shrubs and of a Washington Thorn before they could make any show; all my Hawthorns and flowering Crab are infested with the Cedar fungus; *Cypripedium* spectabile will not bloom for me—the roots live and the leaves appear each spring, but before any flowers appear the stem rots off close to the ground; and the seeds of many herbaceous plants (*Lobelia cardinalis* among the number), repeatedly sown, refuse to germinate. Again, dealers persist in sending me what I do not order, so that my Sweet-shrub turns out to be another species with ill-smelling flowers, though finer foliage (*Calycanthus lævigatus*), *Lonicera flava* becomes the yellow-flowered variety of *L. sempervirens* or else *L. glauca*, *Cocculus Carolinus* invariably puts out leaves of *Menispermum Canadensis*, and even *Trillium grandiflorum* comes up an unattractive Siberian plant for which I have no use.

Some things, however, have grown with a rapidity that is surprising, a *Catalpa speciosa* being the most remarkable example. This was discovered by accident in the fall of 1890, a natural seedling of that year, quite hidden by weeds and coarse grass of the then uncleared ground. In 1892 it bore two large panicles of flowers, and each succeeding year an increased number, the last two or three years producing a full crop of its showy and individually beautiful blossoms. It is now a sturdy tree twenty-two feet high, with a spread of twenty feet and a trunk girth of two feet.

Transplanting has been done both spring and fall, but the latter is beyond question the best season in this climate for most trees and shrubs. Such work has, however, frequently been carried on nearly throughout the winter, whenever the weather and condition of the ground were suitable; and one of the largest deciduous trees on the place, a Black Locust (*Robinia Pseudacacia*), was taken up from the woods and replanted January 16th, 1891. The great benefit of cultivating, manuring and (in summer) mulching around trees and shrubs has been very evident, specimens thus treated having in the same time grown far more rapidly than others of the same kind around which the grass was allowed to grow. Each spring, in March, a circle nearly equal to the ambitus in the case of the smaller trees, but of less extent for the larger ones, is carefully dug up round the base, and given a covering several inches deep of well-rotted cow-manure. In watering during very dry seasons a basin is made around each tree and filled from the hose, allowing the water to sink in and then refilling, until the earth about the roots is well saturated. The soil is then drawn back and covered with a light mulching of

dry grass cuttings or pine needles. One such thorough watering is quite sufficient to carry a tree in good condition through any ordinary season of drought.

Now, near the end of the seventh year of my experiment, I can look back and, through the many mistakes that have become evident, see how various things should have been done at the start. Most of them can be remedied, some of them cannot. Much work remains to be done in the way of transplanting, for at first, according to the custom of most amateurs, trees were planted much too near together and without due reference to their artistic arrangement. One tree intercepts what without it would be a beautiful vista; another is already bending away from the larger growth on one side, and certain shrubs whose mature stature had been underestimated, have quite outgrown the limits assigned to them. At the end of the last transplanting season I was congratulating myself that the hard work was practically done, and I had now before me only the pleasure of watching the progress of my plants; but one summer's growth has quite dispelled this illusion, and the approaching autumn will be scarcely less notable than preceding ones in the amount of digging and changing things about. This would be most discouraging were it not also evident that my ideal, while by no means yet attained, is (barring limitations which preclude the possibility of actual attainment) each year less remote.

Brookland, District of Columbia.

#### *The Geographical Distribution of Forest Trees in Canada.*

By Dr. Robert Bell.

This is a paper read a few months ago before the Scottish Geographical Society, and now issued in separate form from the *Scottish Geographical Magazine* of June, 1897. Dr. Bell has had exceptional opportunities for studying the northern distribution of the Canadian trees, as for forty years he has been engaged every year in exploring, in connection with the Canadian Geological Survey, the extreme northern regions of the continent east of the Rocky Mountains. In 1873 Dr. Bell prepared a map showing the northern limits of the principal trees in the four original provinces of the Dominion, and in 1879 a reduction of this sheet was published in the Report of the Montreal Horticultural Society and Fruit-growers' Association; and in the Report of the Canadian Geological Survey of 1882 he joined to another map a paper containing the latest information upon the northern range of thirty of the principal forest-trees which grow in Canada east of the Rocky Mountains. The present paper, which is accompanied by a map on which the northern distribution of these thirty trees is marked, must be considered a supplement to Dr. Bell's earlier papers, and contains the results of his own observations and those of other travelers and explorers in the far north during the last seventeen years, and these probably in the case of several of the species, at least, must be considered final; although such a comparatively small part of the interior of Labrador has yet been explored, that some changes in the limit-lines now laid down by Dr. Bell for that part of the country will doubtless be needed.

Dr. Bell has had so much experience and has studied so carefully the distribution of Canadian trees and the causes which control their different ranges that his conclusions are extremely interesting and valuable. He finds, for example, that "in approaching their northern limits some kinds of trees become gradually smaller and smaller, and are finally reduced to mere bushes before they disappear altogether, while others terminate abruptly or without any apparent diminution in the average size of the individual trunks. The latter habit is commoner in the southern than in the northern species, and it appears to prevail more in the eastern than in the western parts of Canada." He finds, too, that "it is probable that those trees which bear large numbers of seeds capable of being carried for some distance by the wind, such as the conifers and the Poplars, have now reached the extreme northern limits of their growth, but some other species may be continuing to extend their borders. Indeed, the general tendency appears to be to advance still farther north, as if many kinds of our

trees had not yet had sufficient time to occupy all the territory congenial to their existence." In support of this theory Dr. Bell cites successful experiments which have been made in growing the Black Walnut in the neighborhood of Quebec, although the nearest place where this tree grows naturally is 500 miles farther to the south-west, showing that the range of this tree is capable of being extended over a much greater area than it yet occupies naturally. On Pelee Island, in Lake Erie, the most southern point in Canada, is the only place in the Dominion where the Honey Locust and the Kentucky Coffee-tree are known to grow naturally, although the former flourishes wherever it has been planted through the Ontario peninsula and down the St. Lawrence nearly to Montreal, and the Kentucky Coffee-tree grows to a large size in Ottawa. The Negundo, which has not extended its natural range east of the western end of Lake Superior, grows as well in Montreal, 900 miles further east, as it does in Manitoba, and the Black Ash is perfectly hardy on James Bay, 100 miles to the north of its natural range.

This ability of various trees to grow far from their existing homes is not attributed by Dr. Bell to any change of climate since they attained their present range, as there is no meteorological proof of such improvement, but because sufficient time has not elapsed to permit the "fullest possible territorial expansion of all the species. When frost alone operates to check the northward extension of a tree, there would appear to be no reason why such a species should not grow as far in that direction as it can ripen its seeds, even once in a number of years. When early frost happened to coincide with good seed years many seasons might intervene between crops of ripe seeds, and the natural progress of northward extension would be very slow. The Red Oak, which requires two seasons to ripen its fruit, would suffer a double disadvantage." Dr. Bell notices that the Beech, Elm and Black Ash seldom bear any fruit toward the northern limits of their range.

It is interesting to read that Dr. Bell considers "the greater dryness of the region between Red River and the Rocky Mountains is one of the principal causes of its treeless and partially treeless condition. The former country is called plain and the latter prairie. The other principal cause is the extremes of heat and cold. Some persons have jumped to the conclusion that the plains and prairies have resulted from repeated fires burning off pre-existing forests in modern times. If this were the case the tree-lines in their general westward course would all end abruptly at the edge of the burnt space, and some traces of the various species would still be found in the prairie region. But, instead of this, on approaching the prairie country they all curve gradually to the southward in a concentric fashion, so that what was the northern limit of each successive species now becomes in turn its western boundary. But if other evidence be required it may be found in the prairie flora, the absence of hollows with hillocks accompanying them, left by the bodily upturning of the roots of trees with a large quantity of earth attached, which are always to be found where forests have grown; the comparative scarcity of water courses, and the prevalence of regular rings of boulders around the edges of the nearly circular ponds which have resulted from the action of ice in a treeless region."

While it is probable that the treeless condition of the northern extension of the prairie region and of the plains as distinguished from the prairies, is due to insufficient moisture and to cold, it is evident that the absence of trees from the comparatively well-watered prairie regions of the United States can be largely ascribed to fires, which if they did not originally destroy the forest covering, have certainly prevented a growth of trees, because when the annual burning over of the prairies stopped with the settlement of the country by the whites, trees soon covered or attempted to cover the surface of the ground wherever there was sufficient moisture for tree-growth.

Unfortunately space will not permit us to make longer

extracts from Dr. Bell's paper, which those interested in the subject will find one of the most important contributions to the knowledge of the distribution of the trees of north-eastern North America which has been made.

### Notes.

Mr. J. G. Luehman, for twenty-eight years the assistant of the late Baron von Mueller, succeeds him as Government Botanist of Victoria, and has now been placed in charge of the National Herbarium of Melbourne, with the title of Curator.

A brilliant effect was produced in the table decorations at a private dinner in this city last week by the use of nearly 500 bracts of Poinsettia, which, in five baskets, were arranged on a bed of Asparagus. Many of the bracts measured from eighteen to twenty inches across.

With the completion of the third volume, *The Forester*, an illustrated monthly journal of Forestry, passes from the control of Mr. John Gifford, of Princeton, New Jersey, and in future will be published by the American Forestry Association. The new office of *The Forester* will be at No. 73 Cochran Building, Washington, District of Columbia.

The proposition to perpetuate the memory of William A. Stiles and his labors in behalf of the parks of New York, by naming one of the new small parks for him, has received the endorsement of many of the most prominent professional and business men of this city, whose Memorial has been presented to the Park Commissioners, with whom it rests to pay this fitting tribute to their late associate.

A Catalogue of Fruits has recently been published by the Division of Pomology of the United States Department of Agriculture. This useful and valuable bulletin is the work of a committee of the American Pomological Society, of which Mr. T. T. Lyon was the chairman. Such species and varieties of fruits and nuts as are recommended for cultivation in the United States and in British America are arranged in three divisions: Fruits mainly adapted to northern localities; subtropical and tropical fruits; native and introduced fruits and nuts grown in the open air. The entire region is divided into fifteen pomological districts, with primary reference to the influence of latitude, elevation, prevailing winds and oceanic and lacustrine exposures upon their adaptation to pomological pursuits. Comprehensive and carefully arranged tables show the size, form, color, texture, flavor, quality, season, use and origin, besides the districts in which a particular fruit succeeds.

Mr. James Bateman, who died at Spring Bank, Worthington, on the 27th of November, in his eighty-seventh year, will be remembered as one of the first and most enthusiastic cultivators of Orchids and as the author of *The Orchidaceae of Mexico and Guatemala*, perhaps the most sumptuous and splendid volume which has been devoted to plants. This consists of a series of colored illustrations of life size of a large number of species of Orchids, with descriptive titles and cultural hints to which are added notes, literary, scientific, archaeological and ethnological, the whole work being enlivened by humorous sketches and tale pieces from the pencil of George Cruikshank himself. Forty years ago Mr. Bateman's gardens at Biddulph Grange and Knypersley were famous all over Europe, with their Chinese garden, in which the scheme of a Willow-pattern plate was reproduced, their Egyptian court, their avenue of Sequoias, their groves of Sikkim Rhododendrons, their bulb gardens, Rose gardens, Dahlia gardens, their pinetum and their great collection of Orchids. This last, when Mr. Bateman came to reside principally in Kensington, he presented to the Royal Horticultural Society, to which for more than fifty years he was zealously devoted. His portrait, taken in 1871, is published in *The Gardeners' Chronicle* of December 4th.

At a secret session of the Board of Park Commissioners of the city of Buffalo, held on the 7th of December, Mr. William MacMillan, for twenty-six years the superintendent of the Buffalo parks, was summarily dismissed without even being informed of the nature of his offense. There have been differences of opinion between individual members of the Buffalo Park Board and its superintendent as to the wisdom of permitting the erection in the parks of museums and other buildings not intended for park purposes, and in some other matters about which we do not know all the details. No question, however, has ever been raised as to the strict honesty

and conspicuous ability of Mr. MacMillan's administration. No one has ever doubted his integrity and entire devotion to the best interests of the city of Buffalo, and if, in opinion, he has differed from his commissioners in matters of park administration, he has, we feel confident, been governed solely by his sense of duty to the public. To those who know the Buffalo parks, that city has always appeared particularly fortunate in its park superintendent, who has shown himself one of the best park managers we have ever had in the United States, honest, intelligent, faithful and unbending to the improper demands of the spoilsmen. That the value of his services was appreciated by the people of Buffalo is shown in the numerous letters deploring the unprecedented action of the Park Commissioners, which have been published during the last two weeks in the journals of that city.

In a recently-issued circular, Mr. A. M. Herr, Secretary of the American Carnation Society, names, among the most popular varieties of Carnations now grown, Flora Hill as the best white sort; Harrison's White, Lizzie McGowan, Alaska, Mrs. Fisher and Nivea are other good white varieties which succeed under certain conditions. Mr. Herr considers the pink Triumph superior to William Scott for size of flower, productiveness and keeping qualities. William Scott and Daybreak are ranked as standard kinds. New varieties in this color are Emma Woche and Victor. Abundance is recommended as a small flower for summer. Jubilee is considered the most brilliant scarlet, and Portia and Garfield are listed in this color. Buttercup is praised among yellow varieties, though it blooms sparingly. Eldorado is stated to be the only Carnation of this color which flowers freely enough to be a commercial success. The new Yellow Jacket carries abundant blooms, but is subject to rust. This disease is not considered a serious matter by Mr. Herr, as, notwithstanding its general prevalence, Carnations are improving. Another new yellow variety, Mayor Pingree, promises to bear freely. Iago, Anna Webb, Maceo and Empress are considered the best of the crimson varieties. Helen Keller and Armazindy are praised as the foremost among striped Carnations. The latter is described as bearing flowers of excellent form on stiff stems; not quite as bright as Helen Keller, and the most floriferous of all Carnations. Thomas Cartledge is said to be the only cerise Carnation which it pays to grow for the trade. Daybreak leads among salmon or light pink varieties, and Mrs. McBurney, one of Mr. Hill's introductions last year, is favorably mentioned.

The decks and saloons of the steamer "Magenta," from Keyport, New Jersey, have been crowded with fragrant stacks of manufactured Christmas greens during the past fortnight, and the volume of business has increased steadily until to-day, when the height of the season in the wholesale trade is reached. Nearly all the roping and designs used hereabout come from this portion of New Jersey. Roping has been in special demand this season, and that made of Ground Pine has found ready buyers at from \$1.75 to \$2.00 a hundred yards for the smallest size. Laurel roping is plentiful and may be bought in wholesale lots at from \$1.00 to \$2.00. From 10,000 to 15,000 yards of roping are used in the holiday decorations of each of several large department stores in this city, and churches have been more liberal customers than in recent years. The supply is ample, however; one manufacturer alone has more than twenty workers busily employed in Keanesburg, and besides hundreds of dozens of set pieces, has made up 100,000 yards of roping. Early snows in New Hampshire and Vermont, the region from which much of the Ground Pine is obtained, are responsible for a scarcity of material, as for its dull color. Stars and wreaths made of this graceful creeper are the most costly. Box, which is becoming scarcer each year, is used effectively in combination with grayish lichens, and sometimes the glossy leaves, with their aromatic suggestion of old gardens, are less pleasingly arranged as a foil to bright-colored immortelles. The available supply of Holly is more meagre than last year, but it is profusely berried, and some Holly from the neighborhood of Greenwich, Cumberland County, New Jersey, is unusually handsome, with large brilliant fruits. Loose branches, in cases, are coming from Delaware. Small wreaths made of Holly cost wholesale buyers from forty to eighty cents a dozen on the "Magenta." The supply of these wreaths from Keyport will be smaller than that of last year by from 2,000 to 3,000 dozens. Excepting the increased sale of roping and the manufacture of many large pieces in the design of stars there is no noticeable change in this industry. The season of the wholesale trade practically ends to-day, and the city dealers will be busy from now until Christmas eve disposing of their stock to housekeepers and other retail buyers.

American Trees for America.

LOOKING at the matter broadly, comparatively little, in northern countries at least, has been accomplished toward beautifying the earth's surface by transferring trees from one region to another, although a great deal of time, energy and money has been expended during the last two hundred years in the attempt to do it. It has given to Europe from America the Locust, the great southern Magnolia, the Negundo, the White Pine, several California conifers, the Arbor Vitæ, one or two Thorns, and the Stag-horn Sumach, as truly permanent and valuable additions to the native silva; China has really enriched Europe, as it has eastern North America, with the Ginkgo, the Ailanthus, the Paulownia, the Yulan Magnolias, the Weeping Willow and the flowering Apples; western Asia has sent to Europe the Cedar of Lebanon, the Oriental Plane, the Oriental Spruce and the Cypress, while experiment has shown that of the trees of Europe and western Asia only the White Willows, the Beech, the Elm, the Norway Maple, the Oriental Plane, the Larch, the Box, the Hawthorn and the Mountain Ash can really be depended on in the eastern states to live out their lives in health and beauty. These results may appear small to economists, but certainly all the effort that has been expended in testing exotic trees in Europe and America has been well repaid in the stimulus it has given to the study of botany, in the increase of knowledge and in its few really important practical results. Still, the lesson to be drawn from these two centuries of effort is clearly that the best trees to plant in any particular region are those that grow and thrive naturally in that region. No teacher in such matters is so wise, experienced and unprejudiced as Nature herself, and when her teachings have been followed the best results from tree-planting have always been obtained. The Elms and Maples taken from adjacent swamps and hillsides, which grace the streets of many New England country towns and adorn many New England homesteads, and the Magnolias, Live Oaks and Water Oaks in the streets and gardens of the south testify to the value of native trees; and in England, too, it is the native Oaks, Elms and Beeches which give its distinctive aspect to the land and make its parks the most dignified in the world. Fortunately, in this

country it is not difficult to apply this rule, for no other land is blessed with such a rich, varied and splendid silva. In the southern United States the great evergreen Magnolia, the most beautiful of the broad-leaved evergreen trees of the northern hemisphere, the Live Oak, the Water Oak, the Laurel Oak, the Pecan and noble Bay trees, are available for the planter. In the Pacific coast states the conditions are somewhat different; the number of native trees is smaller than it is in the east, and many of the finest of these are found naturally only at high elevations and cannot be successfully cultivated in the warm, dry valleys in which the people of these states have principally established their homes. Some of the trees which grow in the valleys spontaneously are not ornamental, and are often difficult to cultivate, but some of the noble California Valley Oaks surpass in stately beauty any exotic trees which are likely to flourish in that peculiar climate, and two California conifers, the Monterey Cypress and the Monterey Pine, are generally and successfully grown from Vancouver Island to San Diego. These are both beautiful trees, but California will doubtless always be obliged to depend on other parts of the world for many of her ornamental plants. The trees of the eastern states do not flourish west of the Rocky Mountains; it is not probable that those of Europe or Asia will ever gain much foothold in the soil of California, and it is to Australia, Mexico and other dry countries that California planters will continue probably to derive much of the material needed for the decoration of their parks and gardens.

It is in the eastern and middle states, however, where there is a greater interest in ornamental planting than in other parts of the country, that most is to be obtained from the native silva. That of no other part of the world is richer in handsome trees. From its Magnolias, Oaks, Hickories, Walnuts, Elms and Ashes, its Tupelo and stately Tulip-tree, its Rhododendrons and Mountain Laurels, its Birches and Lindens, its Coffee-tree and Honey Locust, its Sourwood and Sassafras, its Beech, Chestnut, Yellow-wood and Wild Cherry, its Catalpas, its Persimmon and Silver-bell tree, its Flowering Dogwood and Fringe-tree, its Liquidambar and Hackberry, its Sumachs, its Wild Crab and its Hawthorns, planters of deciduous-leaved trees can choose material enough to satisfy every taste and fill every requirement. And among coniferous trees none is more picturesque in youth or more stately at maturity than the northern White Pine, more graceful than the Hemlock, or more symmetrical and enduring than the Red Cedar.

In the past our gardens have suffered from the general ignorance with regard to the true beauty and value of native trees, which appears to have been peculiar to us as a nation. Too often the planter, unable to obtain American trees, has had to rely on the Spruces, Oaks, Ashes, Maples, Pines and other trees of Europe, and these are still too largely used in this country, although it is now known that they are entirely unsuited to our climate and that where they have been used in public parks they must soon be replaced by native species. The lesson has been a costly one, but the experience has not been dearly purchased if we have finally come to realize that Nature has placed for us in America a greater number of beautiful trees, large and small, than is found in any other part of the world, and that American trees are the best for America.

Notes on Cultivated Conifers.—XIII.

ABIES, the name now given to the Silver Firs, is one of the widely distributed coniferous genera with a larger number of species than any other except Pinus. It is well characterized by its flat or more or less quadrangular leaves, without persistent woody bases, spreading on lateral branches in two ranks and leaving in falling nearly circular scars, scattered axillary male flowers, erect cones usually produced only on the upper branches and maturing in one season, their thin entire, rounded scales being often shorter than the bracts, and separating at maturity from the

central axis of the cone. *Abies*, which is usually found on the slopes of high mountains, is represented in North America by ten species, seven of them belonging to the flora of the Pacific states and one to Mexico; it is common in Japan with several species, and is widely scattered over Siberia, the Himalayas, Asia Minor, central and southern Europe and northern Africa. The Silver Firs are pyramidal trees with small branches arranged in regular whorls and usually thin bark filled with large conspicuous resin vesicles; some of the species grow to a very large size, especially those of western America, and others are valuable timber-trees. No genus of conifers probably has contributed more to the beauty of gardens, for nearly all Fir-trees are extremely handsome while young. Their tendency, however, to become thin and lose their lower branches early when they are taken from cool mountain slopes makes the first thirty or forty years of the lives of these trees the most attractive period of their garden career.

The species which grows in the swamps and on the mountains of the north-eastern part of this continent from Labrador and the shores of Hudson's Bay southward to the high mountain peaks of Virginia, the so-called Balsam or Balsam Fir (*Abies balsamea*), is a beautiful tree while it is small, with lustrous foliage and dark purple cones. Its beauty, however, is short-lived in cultivation, and the tall, narrow, scrawny Balsams still so common in the neighborhood of New England farmhouses show how worthless it is for any scheme of permanent decoration. The dwarf spreading Silver Fir, only a foot or two high, frequently cultivated under the name of *Abies Hudsonica*, although it has not produced cones and nothing is known of its origin, is probably a depauperate form of *Abies balsamea*. Beissner describes a number of other seminal varieties of this tree which are grown in Europe, but I have never seen any of them. A seedling form sent several years ago to the Arnold Arboretum by Robert Douglas is distinct in its broader and more crowded leaves.

The second eastern American Silver Fir, *Abies Fraseri*, a small tree found only on the highest slopes of the southern Appalachian Mountains, will probably not be of more permanent value here as an ornamental tree than the northern Balsam, from which it chiefly differs in the long exserted recurved bracts of the cone-scales. The southern tree appears to have been common in European collections about the beginning of the century, and then probably entirely disappeared from gardens, as for many years seeds of *Abies balsamea* were sold for those of *Abies Fraseri*, and most of the plants now cultivated under that name are certainly wrongly named. For nearly twenty years, however, *Abies Fraseri* has been growing in the Arnold Arboretum, where it is perfectly hardy, produces cones and is still good-looking.

Of the Silver Firs of western America the most valuable here as a garden plant is *Abies concolor*, the White Fir of the southern Rocky Mountains, of the California Sierras, of the Pacific coast ranges, of many of the interior mountains of the south-western states and of northern Mexico. No other *Abies* flourishes in such hot, dry regions or has been able to sustain itself among such climatic hardships; and it is not surprising that a tree, which is equally at home in the sea-fogs which sweep in from the Pacific over the California coast ranges as it is on the mountains of Lower California, southern Arizona and central Colorado, should find little to fear from the cold blasts and hot summers of New England. Both the California form, with its rather shorter and greener leaves, which in England is still called *Abies Lowiana*, and in this country sometimes *Abies Parsonsii*, and the handsomer Colorado form with longer blue leaves, are perfectly hardy in New England. The oldest specimens here of the California tree are already becoming somewhat thin and are beginning to lose their lower branches, and so have passed the period of greatest beauty. The largest of the Colorado plants, however, in eastern gardens, which are now probably twenty-five feet in height, are still perfect in habit and density of foliage, surpassing

in vigor and in loveliness of form and color all the *Abies* hardy in New England, and are still as full of promise as trees of the same age in sheltered ravines of the Rocky Mountains. However ugly and unsatisfactory old trees of this Fir may become here later, it deserves a place in every garden for the beauty of its early years.

None of the other western American *Abies* promise to be of much value to us here in the east. *Abies lasiocarpa* (*A. subalpina* of Engelmann), which is the most widely distributed of the North American species, ranging as it does from Alaska southward over all the high interior mountain systems to northern Arizona, has been cultivated for many years in the Arboretum, where it is perfectly hardy, but grows very slowly, forming here broad compact pyramids of pale blue-green foliage. A tree of the north and of high mountains, where it grows up to the timber-line, *Abies lasiocarpa* will probably never attain at the sea-level a large size or show the narrow spire-like pointed head of dense foliage which makes this tree such a beautiful object in the alpine forests of the west and the not unworthy associate of the lovely Patton's Spruce. Among the seedlings raised at the Arnold Arboretum is a plant of this *Abies* which has remained a low flat cushion only a few inches in height, which now promises to be one of the most attractive of the dwarf hardy conifers.

*Abies amabilis*, *Abies nobilis*, *Abies magnifica* and *Abies grandis*, the four largest Fir-trees in the world, can be kept alive here in sheltered positions, although none of them will probably ever be of any permanent value in our plantations. Of these four trees *Abies nobilis* of the mountains of Oregon and Washington is, perhaps, the hardiest, and fairly healthy specimens can occasionally be found in eastern gardens. *Abies amabilis*, which has always grown badly in cultivation, even in Europe, is a more northern tree. It grows, however, very slowly in the eastern states, and gives little promise of ever becoming large enough to show its true character and beauty. The other American species, *Abies venusta* of the Santa Lucia Mountains of California, the least widely distributed of all the *Abies*, and *Abies religiosa* of Mexico, are too tender for New England and the middle states, so that of the ten American species only *Abies concolor* is really valuable in eastern gardens where, moreover, it will possibly be beautiful only during the years of its early vigor.

In Japan there are probably only five species of *Abies*, although a number of others have been described at different times. These trees are all hardy in New England, where they grow with varied success. The largest and most beautiful of the Japanese Firs is *Abies firma*, which I have seen in Japan only in cultivation, when it often attains a height of 120 feet and produces a tall straight stem from four to six feet in diameter. As it grows in temple gardens near Tōkyō, where the climate is not very unlike that of Charleston, South Carolina, it is the handsomest of all Firs, distinguished by nobility of port and bright green and very lustrous long rigid leaves which are sometimes sharply pointed and sometimes notched at the apex. This beautiful tree has generally proved a disappointment in the United States and Europe. It is very hardy even in eastern Massachusetts, where it grows rapidly and where in the Arboretum it has produced cones. In this country, however, it is almost always ragged and miserable in appearance, and it evidently needs a warmer and moister climate than that of the northern states to develop its beauties.

*Abies homolepis*, which is usually cultivated in our gardens under the name of *Abies brachyphylla*, is the common Fir of central Japan, where it abounds at elevations between 4,000 and 5,000 feet above the sea, and where it is scattered singly or in small groups through the Birch and Oak woods which exist just below the subalpine Hemlock forest belt. It is a massive, although not a tall, tree, and in old age is easily distinguished from all other Firs by its broad round head, the branches near the tops of the trees growing more vigorously and to a greater length than those lower on the

stems. This peculiarity is seen even in the young plants in our gardens, on which the short lower branches are usually soon shaded by those above them. The pale bark, long crowded leaves, dark green on one surface and silvery white on the other, and the large purple cones make this a beautiful tree. It grows here very rapidly and is perfectly hardy, but probably will be early disfigured by the loss of the branches near the base of the trunk. *Abies Veitchii* forms forests of considerable extent on the high slopes of Fugi-san and is another handsome tree with lustrous dark green leaves, silvery white below. From *Abies homolepis*, to which it bears considerable resemblance, it may be distinguished by its shorter and more crowded leaves, by its more slender branches coated with fine pubescence, and smaller cones. This tree was sent to the Parsons Nursery in Flushing nearly forty years ago by Mr. Thomas Hogg, and was cultivated in the United States under the unpublished name of *Abies Japonica* for many years before it was introduced into Europe. It is very hardy in eastern Massachusetts, where it has produced cones, and in its young state, at least, is an exceedingly beautiful tree of slender pyramidal habit and dense lustrous foliage.

*Abies Mariesii*, which appears to grow only on a few of the high mountains of northern Hondo and at one point on the southern coast of Yezo, is a compact, shapely pyramidal tree forty to fifty feet in height, with crowded branches covered with short, dark foliage, pale below and abundant large dark purple cones. In this country and Europe, although it appears to be hardy enough, *Abies Mariesii* is a feeble grower and gives little promise of success.

The Silver Fir of Yezo (*Abies Sachalinensis*) is a tall pyramidal tree with pale bark, long slender dark green leaves and conspicuous white buds which make it easy to distinguish this species at any time. It is not rare on the hills of central Yezo, and in the northern part of that island and in Saghalin it is said to form great forests. In the neighborhood of Boston, where it is very hardy, *Abies Sachalinensis* grows more rapidly than any of the other *Abies*. The largest plants are, however, only five or six feet high and too young, of course, to give any idea of the permanent value here of this tree.

In China *Abies* is less common than it is in Japan, although a still little-known species has been found by Dr. Augustine Henry on the mountains of Hupeh, in the central part of the empire. Further north the Silver Fir of Siberia (*Abies Sibirica*) ranges eastward to the valley of the Amoor River and to Kamtschatka. This is a very hardy tree in New England, of slender pyramidal habit and narrow dark green lustrous leaves, in form and color not unlike *Abies Sachalinensis*. I do not know that it has produced cones here yet, although the largest trees are from twenty-five to thirty feet in height and have already passed the period of their greatest beauty. This is one of the earliest of the Silver Firs to begin its growth in the spring, and in western Europe it is often injured every year by spring frosts. The Himalayan Fir (*Abies Webbiana*), which sometimes grows to the height of 150 feet, with a trunk ten feet in diameter, and is distributed from Bootan to Afghanistan at elevations between seven and thirteen thousand feet above the sea, is one of the handsomest of the whole genus, with leaves which are dark green and lustrous on one side and silvery white on the other, and large bright purple cones. This tree grows only moderately well even in sheltered positions in western Europe, where it frequently suffers from late spring frosts, but in some of the gardens of southern France and northern Italy it appears to be perfectly at home. I have never seen a specimen in this country, and the Himalayan Fir would certainly not be hardy in the north-Atlantic states. In south-western Asia and south-eastern Europe there is an interesting group of *Abies*. The most widely distributed and best known of these trees is the common Silver Fir of Europe (*Abies pectinata*), which is distributed from central France to middle Russia, and grows also on the mountains of Macedonia and Greece and on some of those of the eastern provinces of Asia Minor. This is the

Silver Fir of the silviculturists of central Europe, who consider it a valuable timber-tree, although the wood which it produces is inferior to that of the Spruce. Long a popular ornamental tree in England, *Abies pectinata* was probably first brought to this country nearly a century ago. It has never proved very successful here, although occasionally a healthy specimen fifty feet high or more can be found in some old garden of the middle states. In New England, except in very sheltered positions, it suffers from the cold and usually disappears at the end of a few years. Among several abnormal forms of this species the most distinct is the variety *pendula*, a handsome tree with distinctly pendulous branches; variety *nana*, a handsome bush, which in time often loses its dwarf habit and grows into the normal form, and the variety *columnaris* with erect branches pressed closely against the stem and short crowded leaves.

Another of this group, *Abies Cephalonica*, is a distinct-looking tree with branches long in proportion to the height of the stem and crowded rigid sharp-pointed leaves. It is a native of Mount Enos, on the island of Cephalonia, and has been an inhabitant of English gardens since 1824. The Cephalonian Fir is quite hardy in eastern Massachusetts, and there are specimens in Mr. Hunnewell's pinetum which are from thirty to forty feet in height and have produced cones for several years. Large plants in this country, however, are not handsome, and the Cephalonian Fir is probably one of the least desirable of the genus as an ornament of our gardens. *Abies Apollinis* and *Abies Reginæ-Amaliæ*, natives of the mountains of Greece, are usually considered merely geographical forms of *Abies Cephalonica*; they are both hardy here in a young state and the largest plants which I have seen in this country, still only a few feet high, are handsome. *Abies Nordmanniana*, another of the Silver Firs of south-western Asia, has been the most generally planted of all the Old World *Abies* in the northern states, where it has proved very hardy and one of the most beautiful and satisfactory of the exotic conifers which have been tried here. The largest plants in the eastern states are now from fifty to sixty feet in height and are still well furnished with branches clothed with beautiful crowded leaves dark green and lustrous above and silvery white below. The Nordmann Fir is a native of the mountain forests east and south-east of the Black Sea, including the western spurs of the Caucasus, and in its native country it is said to grow to the height of 150 feet, with a trunk five or six feet in diameter, in forests of Oaks, Horn-beams and other deciduous-leaved trees. A number of seminal varieties which I have not seen are cultivated and described by European nurserymen.

A more beautiful tree, perhaps, at least in its young state, than the Nordmann Fir, although still much less well known in American gardens, is the Cilician Fir (*Abies Cilicica*), a more southern species confined chiefly to high elevations on the Taurus and anti-Taurus, where it is the companion of the Cedar of Lebanon, and to the Lebanon range itself. Rarely seen in western Europe, where it suffers seriously from spring frosts, the Cilician Fir grows admirably in New England, where it forms splendid broad-based, dense pyramids covered with lustrous narrow leaves conspicuously marked with pale stomata. This is a difficult tree to obtain; it has not been long enough in this country to produce seeds here; apparently they never ripen in western Europe, and it seems impossible to obtain them from the remote and inaccessible forests which are the home of this tree.

The handsome Algerian Silver Fir (*Abies Numidica*), which grows well in England and some parts of France, is probably nowhere hardy in the northern states; and the beautiful Spanish and north African *Abies Pinsapo*, which is one of the handsomest conifers cultivated in central and western Europe, where it has already grown to a good size, can only be kept alive here in sheltered situations, and will never show its real beauty in the northern states.

This brief review of the species of Taxids and Conifers which have been tried in our gardens, or which are likely

to succeed here, shows that the number of species of these great families which can be really depended on to grow permanently in this part of the world is a small one. *Pinus Strobus*, *Pinus resinosa*, *Pinus rigida*, *Picea alba*, *Picea rubra*, *Juniperus Virginiana*, *Juniperus communis*, *Thuya occidentalis*, *Tsuga Canadensis*, *Ginkgo biloba*, *Larix Americana* and *Larix Europea* are the only handsome trees of these families which have shown themselves able to grow in this climate to a large size and preserve in cultivation here their mature beauty. All of these, with the exception of the *Ginkgo* and the European Larch, belong to our northern silva. In a second list may be placed *Abies concolor*, *Pseudotsuga taxifolia* and *Picea Engelmanni* of the Rocky Mountains, *Taxus cuspidata*, *Abies homolepis*, *Abies Veitchii*, *Picea Ajanensis*, *Pinus parviflora*, *Thuya Standishii* and *Sciadopitys verticillata* of Japan, *Pinus Koraiensis* of Corea, *Pseudolarix Kämpferi* and *Pinus Bungeana* of northern China, *Abies Nordmanniana*, *Abies Cilicica* and *Picea orientalis* of Anatolia. The trees in this second list all do well in the northern states, where they have been grown from twenty-five to fifty years, although none of them have been tried long enough yet to show their ability to thrive permanently here. In a third list of species promising in this climate, but still less tried than those of the second list, may be placed *Abies Sachalinensis*, *Pinus densiflora*, *Abies lasiocarpa*, the two Japanese Hemlocks, *Thuya plicata*, *Tsuga Caroliniana*, *Tsuga Pattoni*, *Picea Omorika*, *Larix Dahurica* and *Tumion nuciferum*. If these all succeed here the number of plants of these families which we can really depend on is still very small, and the permanent decoration of the parks and gardens of the north-eastern states will have to be largely made of broad-leaved trees, which flourish here almost as well as in any other part of the world, and of a comparatively small number of species of *Taxids* and *Conifers*.

C. S. S.

### The Botanic Garden of Smith College.

#### A STUDY OF AN EDUCATIONAL ADAPTATION.

IT is plain to all who read the signs of the times that the present trend of botanical activity is toward the study of the phenomena of the life of plants. The facts of plant-structure, and of plant-relationships as suggested by resemblances of structure, have been relatively so well studied that for the present and near future the most attractive problems must lie in the investigation of the causes of structure. The plant static needs to be, and is being, explained by the study of the plant dynamic. But as investigation leads, so must education follow. For the systematic pursuit of physiology and ecology, however, a botanic garden with a well-proportioned greenhouse system is essential; and it is rapidly coming to pass that a college must provide these if it is ambitious to keep abreast of the general advance.

It is in this spirit that Smith College has established its Botanic Garden. As an attempt to realize with fair rapidity and minimum expense, a preformed plan which should express the optimum of adaptation to the present demands and indicated tendencies of botanical education, this venture is, perhaps, without exact precedent, and its results must possess, botanically and educationally, a far more than sectional interest.

The history of this Garden is very brief. In 1891 the trustees of the college, following the recommendation of President Seelye, to whose initiative and constant interest the Garden owes everything, decided to attempt to combine the beautifying of the college grounds with the formation of a scientifically planned botanic garden which should serve as an adjunct to the department of botany. Messrs. Olmsted, Olmsted & Eliot were engaged to draw up the plans, and in 1892 planting was begun. The next year a small greenhouse was built. In 1894 the position of Director of the Botanic Garden and Professor of Botany was established and an appointment made. Since then, though with large changes in the original plans made necessary for practical reasons, development has gone steadily on. Some progress has been made in the school of trees and shrubs; the herbaceous garden is nearing completion; the greenhouses are finished and stocked; the work of administration is systematized.

The college campus contains about thirty acres, including the space occupied by the nineteen buildings (see map on p. 513). It

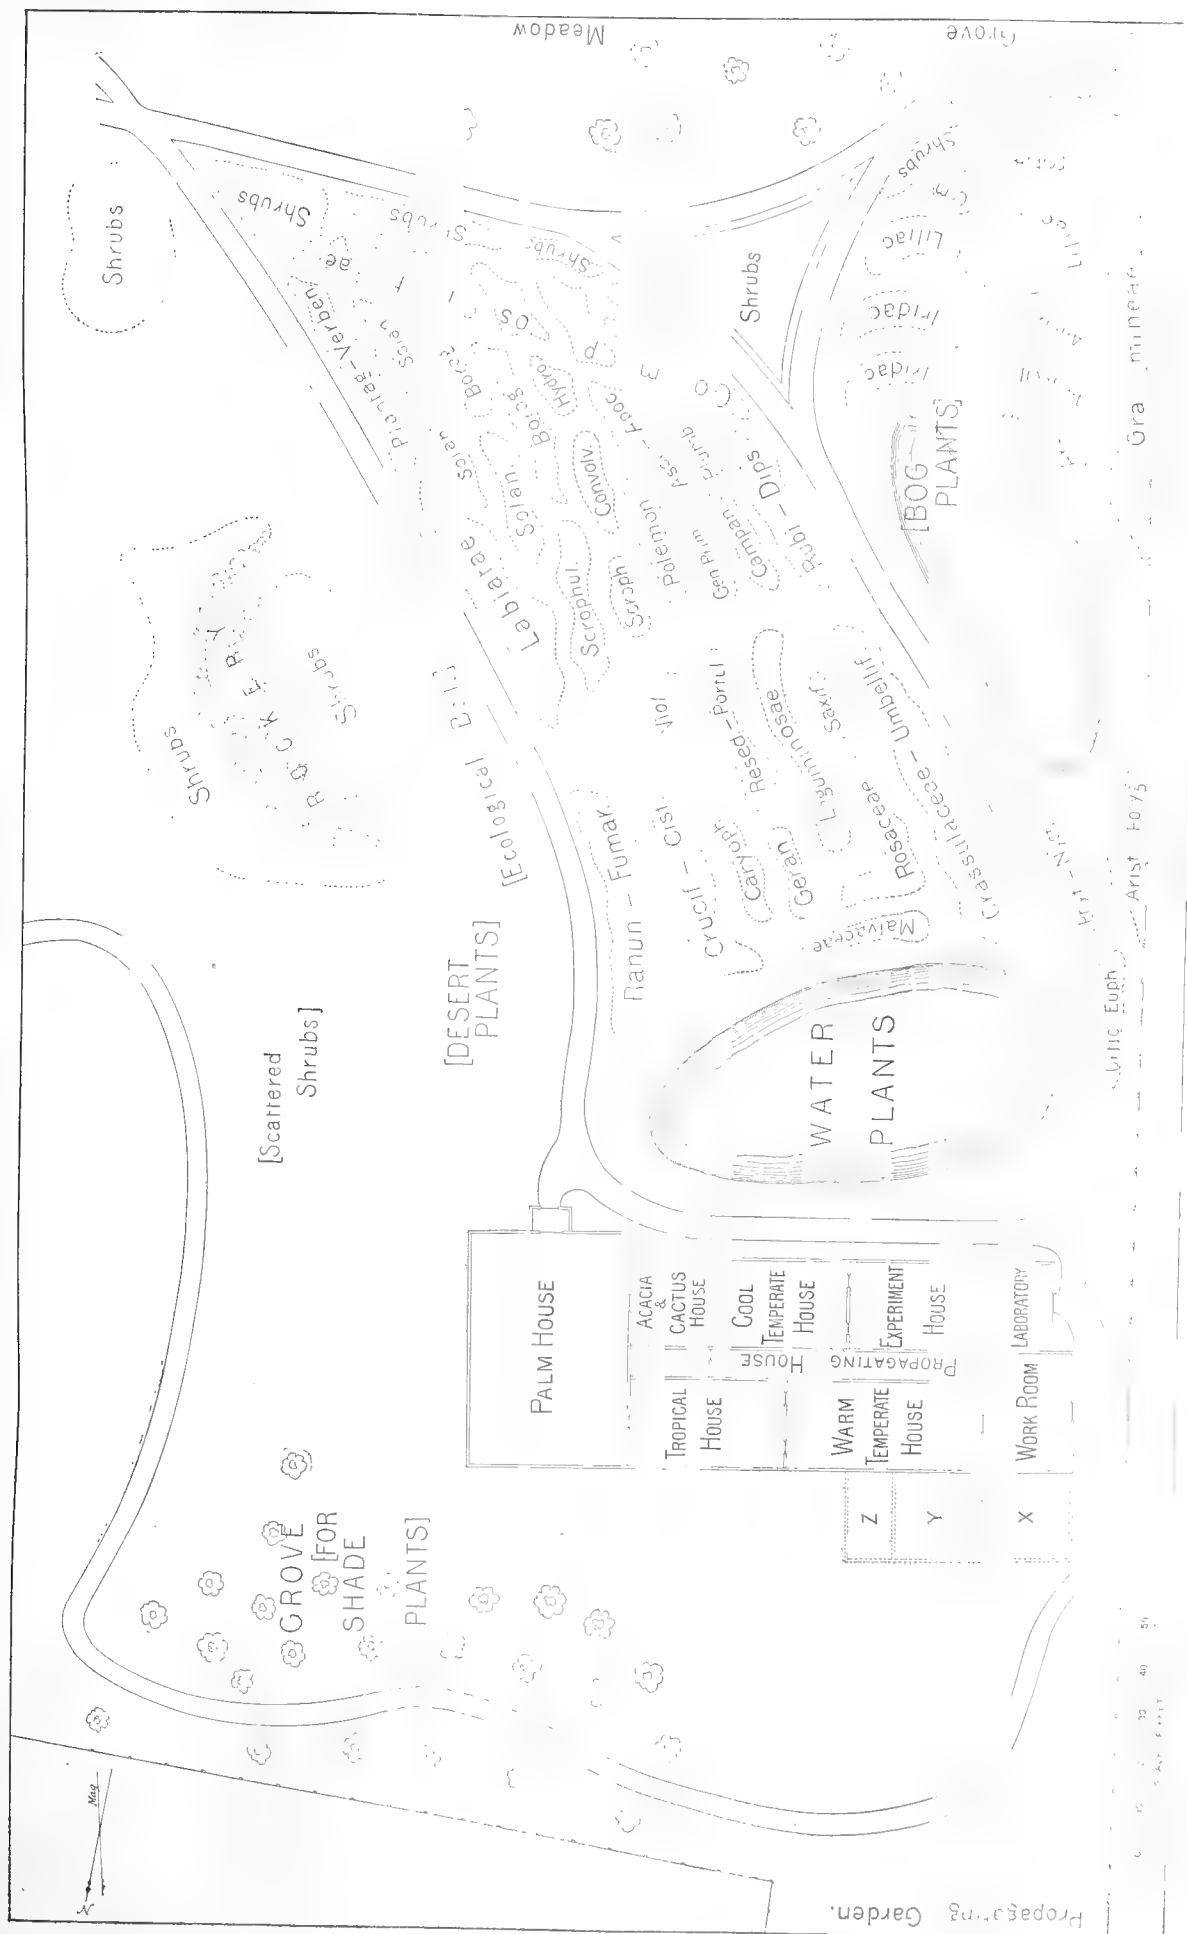

is roughly quadrangular in shape, and, as to surface, consists of two nearly equal plains differing fifteen to twenty feet in elevation, the higher on the north-east, with a slope of varying steepness between. The soil is mostly poor. There were originally some fine trees on the grounds, and two or three good vistas and open spaces, and from several points there are beautiful views of the distant hills or over a little lake and the woods beyond. Happily, the campus is not a public thoroughfare. Except for the herbaceous garden and a large open meadow, the entire grounds are divided by imaginary lines into sections, each devoted to a single family of woody plants, and arranged in sequence according to the natural system of Bentham and Hooker. Within the limits of the family it is intended to group the trees and shrubs about the buildings chiefly for artistic landscape-effect. Naturally, development in this part of the Garden must be slow. None of the good trees or shrubs originally on the grounds will be disturbed, but all new planting will be made to accord with the new plans. Of trees and shrubs 276 species, in forty-five families, are now growing on the grounds.

In the north-west angle of the campus, and on the lower level, about two and one-half acres have been devoted to the herbaceous garden. It has four parts: (1) the systematic section, (2) the ecological section, (3) the greenhouses, (4) the propagating garden.

A systematic section must always form the centre of any complete botanic garden, for name and relationships are to botanists practically the most important things about a plant. The accompanying plan sufficiently shows the arrangement of this section, which follows the system of Bentham and Hooker, and aims to illustrate the systematically important families and genera, not of New England alone, but of the world. It now contains, along with the ecological section, more than 1,200 species, in seventy-eight families.

For the many plants which will not grow in open beds because they are fitted to a different situation, and that the principles of their adaptation to their particular habitats may be shown, it is necessary to supply those habitats. For this reason we have the ecological divisions. The pond is well stocked with water-plants selected to show the different ways in which plants overcome the drawbacks of that mode of life. A bog is being prepared for bog and marsh forms. The rockery is completed and well stocked with alpine and other rock-dwelling species. Behind the greenhouses a grove of native trees and shrubs has been started in which the shade-loving plants are to be placed. Desert plants will have a place on the sunny bank near the rockery, and strand plants will ultimately be present also. In addition to the ecological groups, there are important principles, needing illustration, of adaptation to particular modes of nutrition, exposure to light, the climbing habit, protection, movements, locomotion (dissemination and pollen-transfer), etc. For these, and for illustrating principles of form and color, a series of beds will be made along the space reserved for the purpose west of the rockery. An economic section has not yet been arranged for, though in a complete botanic garden it should be present. The shrubs which have a place in the herbaceous section are all of special educational interest.

The greenhouses stand in a sheltered corner with a high terraced bank on the north and east. They are a gift to the garden from Mr. E. H. R. Lyman in memory of his mother. They are built and equipped in the most thorough and modern manner. Their divisions are, of course, primarily climatic, but within each there is an attempt at an ecological arrangement. The Warm Temperate House (18 by 42 feet, inside measurement) contains, in addition to plants proper to that climate, a raised tank, eight feet square, in which principal types of water-plants are constantly growing, and a grotto or rock-work, over which water is always trickling, for Liverworts and similar amphibious forms. The Tropical House (18 by 35 feet) contains special collections of Orchids, Begonias and Ferns, with other smaller tropical types. The Palm House (50 by 35 by 25 feet high) is the best furnished and most attractive of the range. Its chief feature is the great central bed in which selected types of larger tropical vegetation—Palms, Bamboos, Figs, Dracænas, Musas, Crotons, Aroids, Ferns—are growing directly in the earth, and form a jungle instructive of many principles of adaptation. The great success of this bed illustrates the value of planting out large plants wherever possible. Other collections in this house are the climbers, *Nepenthes*, *Bromeliads*, all chosen for principles which they illustrate. The *Acacia* and *Cactus House* (17 by 18½ feet) is filled with forms to show relations to the desert habit. The Cool Temperate House (18½ by 33 feet) contains forms of our own latitudes, and in it large quantities of materials are raised for elementary instruction. In it also is another tank, a group

THE BOTANIC GARDEN OF SMITH COLLEGE

1897

of Sarracenias, and later are to be added halophytes and alpinas. The Experiment House (18½ by 33 feet) is chiefly devoted to the practical study of plant physiology by the advanced students. Here a practicum is carried on in which each student works through a series of experiments upon the nutrition, growth, irritability and other vital operations of plants. The laboratory is used by them in this work. A Propagating House (5 by 66 feet) and the workroom, with the boilers beneath, complete the series. This brief sketch does but scant justice to the botanically and educationally interesting contents of the houses. It is difficult to estimate the number of species in them, but it will give some idea to state that they contain 28 species of Palms, 15 of Aroids, 16 of climbers, 15 of economic plants, 56 of Ferns, 8 of Sensitive plants, 78 of Cactaceæ, 37 of Acacias, etc., 20 of Aquatics, 15 of Insectivora, etc. It is not, however, accumulation, but selection, which is the guiding principle here as throughout the Garden.

In practice this arrangement of the houses in parallel series has proved both economical in heat and labor, and convenient for study, and can be strongly commended. There is but one change needed, a larger cool greenhouse, for the present one is too small. In time the Experiment House will be taken for this purpose and a new house and laboratory built on a space reserved along the north of the present range.

The Propagating Garden contains the usual equipment of frames, bulb houses, etc.; in it plants are grown on for winter-flowering, and woody plants for the School of Trees and Shrubs.

A great element in all adaptation is size. This Garden is not for the public, nor even for University work (which Smith College only permits and does not encourage), but is intended for the botanical education of a growing college of about a thousand undergraduate students. This, and economy, have made the Garden the size it is, and it is believed to be ample for a long time to come. The relatively large size of the greenhouses is made necessary by the nature of the American college year, with a winter session and no summer session. Such houses as these, since they allow the study of living plants to be carried on practically regardless of season, both permit the arrangement of the botanical courses upon the best educational principles, unhampered by the usual practical difficulties, and also allow of constant improvement, through experiment, in the providing of the most illustrative materials, in the best condition, for the most thorough, vivid and economical instruction of the different grades of students. It is plain that efficiency in these respects presupposes a gardener of special and unusual qualifications; such is our head-gardener, Mr. E. J. Canning, to whom most of the success of the Garden is due.

Of great importance to any American college contemplating such an equipment is the question of cost, which in this case also has had to be considered with great care. Since the grounds of a college must be kept in good order in any case, and their improvement ought to go steadily on, the additional cost of developing them on a botanical system is not great, and the chief expense is in the care of the herbaceous garden and greenhouses. The winter force in this Garden consists of a head and second gardener, aided by about half of the time of one laborer; the summer force consists of the two gardeners, with from three to four laborers. Materials for stocking garden and greenhouse are, thanks to the generosity of the older gardens of Harvard, Washington and St. Louis, readily obtainable as gifts, or else may be chosen from the exchange seed-lists of the gardens of Europe. Following their example, this Garden issues an annual exchange list, which is sent to all of the great gardens of the world, for which theirs are received in return. During the past year we received from other gardens 744 packets of seeds, all we could use, selected from 23 seed-lists, and in return sent out 1,368 packets selected from our own by thirty gardens, nearly all European. Another question of cost often raised is as to the profit of maintaining a garden when college is not in session at its best time. The answer is, first, if a garden is wanted at all, its maintenance through the summer must be reckoned as a part of its cost, and, second, it is more useful in summer than it seems. The blossom is not always the important part of the plant, nor is the study of flowers all of botany; it is possible within certain limits to select forms which blossom early and late; summer-blooming materials may now be cheaply and well preserved in formaline for winter use; and finally, summer schools may fully utilize the summer condition of a garden.

Although in this sketch the botanical or educational aspect of the Garden has had first place, it is not to be inferred that its æsthetic side is neglected. Plants for beauty as well as plants for use stand in our beds and houses and are open to

all. The Garden is yet too new, and in some respects too incomplete to have ripened to full beauty. But in time and with constant growth, it may yet come to pass that there will gather about the gardens of Smith College something of that charm which makes the gardens of Oxford almost sacred ground, where all that is dearest to vigorous and scholarly youth is associated with all that is most beautiful in man's friendship with Nature.

Northampton, Mass.

William F. Ganong.

## Plant Notes.

### The Fruit of Sequoia.

IN *The Silva of North America* the fruit of Sequoia is described as maturing during the first season, although both Engelmann, in *The Botany of California*, published in 1880, and Masters, in *The Journal of the Linnæan Society* (xxx., 22), published in 1895, stated that it did not mature until the second season. It is now evident, however, that the statement in *The Silva* was based on the study of insufficient material, and that so far, at least, as Sequoia Wellingtonia is concerned, the fruit does not ripen until the second season. This fact has been pointed out to me by Miss Alice Eastwood, the curator of the herbarium of the Academy of Sciences of California, who has made a careful investigation of the subject, and in a recent letter says: "I think that this is what happens. The trees bloom early, probably in February or March, and the cones grow during the following summer and, perhaps, also during the winter. The next spring they are of mature size and the seeds are ready to germinate. The cones open during the following summer, in August or September, after the hot, dry season." To Miss Eastwood, too, I am indebted for the specimens which show the accuracy of her observations, and which are reproduced in Mr. Faxon's drawing on page 515 of the present issue.

So far as I have seen there is no reason to believe that the second species, the type of the genus, *Sequoia sempervirens*, does not mature its cones in one season.

C. S. S.

### Notes on the Botany of some Southern Swamps.

THE following notes were gathered the past summer during a journey especially devoted to collecting and studying the plants of swampy regions in the states of Missouri, Arkansas, Louisiana, Mississippi, Alabama and Florida.

Leaving St. Louis on the night of July 27th, I arrived at Little Rock, Arkansas, early the next morning, and at sunrise heard the shrill cries of mocking-birds as they left the trees where they had passed the night, announcing, as well as the appearance of Cotton in the fields, the Crape Myrtle and Pride of India trees in the yards, and the Paper Mulberries in the streets, that I was entering the sunny south. The principal indigenous plants observed near the banks of the Arkansas River at this place were the Willow Oak, Spanish Oak, Cow Oak, Catalpa, Sweet Gum, Cassia occidentalis, C. Tora, Jussiaea decurrens, Rhexia Mariana and Hibiscus lasiocarpus. As my object was to study the swamp flora, I did not attempt to make a collection here, but proceeded to Alexandria, Louisiana, noting as good collecting points Varner, Arkansas, and Mer Rouge, Louisiana, for the return trip.

On reaching Pine Bluff, Arkansas, I found that Albizzia Julibrissin was common in cultivation, and that Sabal Adansonii was abundant in low woods along the Arkansas River. Big trees became common from Walnut Lake, Arkansas, southward. Hicoria aquatica, Aralia spinosa, Populus heterophylla and Sesbania macrocarpa are very common beyond Pine Bluff, Arkansas, while the Long Moss (Tillandsia) became conspicuous at Parkdale, Louisiana. Passing through Alexandria and reaching Melville, Louisiana, I found Fraxinus pubescens, var. lanceolata, Brunnichia cirrhosa and Quercus lyrata common in the swamps. Here I paid little attention to the upland flora,

the main object of my journey being to collect swamp specimens and to make special search for *Leitneria Floridana*, and an Ash-tree which I had found several years ago in the swamps of south-eastern Missouri, and described as *Fraxinus America profunda*.\* Later studies and observations have shown that this tree is abundantly distinct from the White Ash and from all other species of the genus, and I now propose to give to it full specific rank as *Fraxinus profunda*, under which name it will appear throughout these notes. Believing that these two plants would be found at many stations between Missouri and Florida, I watched for them carefully throughout the trip, with what success the reader will learn later.

Leaving Melville, I went to Bayou Goula, Louisiana, but as the bayou was as dry as the streets of St. Louis I did not stay there long, but went on to White Lake, where there is a large Cypress swamp, which I examined thoroughly, failing, however, to find any *Leitneria* or *Fraxinus profunda*, although the Green Ash was present in goodly

I gathered specimens of a fine *Clematis* in fruit, which appears to be undescribed.

Leaving the Chattahoochee River, I went down the Apalachicola, looking with reverence on *Tumion taxifolium* and *Taxus Floridana*. Arriving at Apalachicola, I visited, in company with Dr. Chapman, the St. Mark's branch of the Apalachicola, where Dr. F. Roth found early last spring *Fraxinus profunda*, and when Dr. Chapman showed me what he had called the Red Ash I was pleased to recognize the species I was looking for. The fruit had already fallen, but I took a few leaf specimens that I might record the locality. The trees here were small, being only from twenty to thirty feet in height, with trunks swollen at the base, as I had found them in Missouri. Here I saw magnificent Cabbage Palms at least fifty feet in height, their tall wide-leaning trunks standing out in bold relief against a background of Swamp Hickories, Pecans and other deciduous-leaved trees. Near the margin of the river dwarf Palmettos flourished with great clumps of *Rhyncospora*

Fig. 66.—*Sequoia Wellingtonia*.—See page 514.

1. A young cone, gathered in July. 2. A fruiting branch of the same year, gathered in October. 3. A mature open cone of the previous year, gathered in October.

numbers. Here I first saw the French Mulberry (*Calli-carpa Americana*), with its attractive bright reddish purple fruits; and here also I made the acquaintance of the beautiful *Aspidium patens*, which covers with tall graceful fronds the higher parts of this swamp.

Leaving White Castle, I went on to Orleans without seeing any suitable place to stop on my return, and then proceeded to Mobile, Alabama, passing several days at Spring Hill, in southern Alabama, collecting with Dr. Mohr, who introduced me to a number of the most interesting southern plants. On the borders of swamps in this region I was surprised to find the Crape Myrtle, the Pride of India, *Albizia Julibrissin* and *Zizyphus Jujuba* thoroughly naturalized. Leaving this most delightful collecting-ground, I passed on to Florida to seek for the two trees on the Chattahoochee River, stopping on my way to examine several swamps along the route without finding anything of importance until I reached the Chattahoochee River, where

corniculata and its variety *patula*. Associated with the beautiful Mallow, *Kosteletzkya Virginica*, and the fine leguminous plant, *Vigna luteola*, a few specimens of *Leitneria* were also observed; they were, however, quite small with narrow leaves. At Apalachicola I examined the marshes north of the town, finding there another clump of *Leitneria*, the plants being larger than those which I had seen on the St. Mark's River, and a broad-leaved Willow which appears to be undescribed. I was much elated on finding here some handsome leguminous plants with fine large scarlet flowers, which proved on examination to be *Daubentonia longifolia*, which has become introduced into waste places and is spreading along roadsides. Returning from Apalachicola I went to the Chattahoochee River and Spring Hill, Alabama, and then homeward by the way of New Orleans and Alexandria without seeing any further signs of *Leitneria* or *Fraxinus profunda* near these places.

Going on to Mer Rouge, I found the White Ash common in that locality, this being the first place in which I had noticed it. There was no sign, however, of the Green Ash,

\* *Ann. Rep. Missouri Bot. Gard.*, v., 147 (1894).

which is common from south of Mer Rouge to New Orleans. Here I saw also the common Papaw, which I had not observed further south. Leaving Mer Rouge, I went to Varner, Arkansas, where I spent two days in examining the country near the railway station. Here I observed the French Mulberry in abundance, and also the White Ash. The second day I went some distance into the lowlands, across Cypress Creek, and here I found *Fraxinus profunda* in great quantities, besides plenty of Green and White Ashes. I examined several hundred trees of *Fraxinus profunda*, but could not find any fruit, although I secured good leaf specimens, as well as those of *Leitneria*, which is also abundant here. My guide told me that the people in the neighborhood called *Fraxinus profunda* Pumpkin Ash on account of its being swell-butted, a character which I had already noted in the trees in Missouri. This Ash grows here to a height of one hundred feet, with a trunk eighteen inches in diameter, and is larger and better developed and more abundant than I have seen it elsewhere. The *Leitneria* was also larger than at Apalachicola, being here about twelve feet in height, with stems nearly four inches in diameter. The Arkansas River is only six miles distant from this point, and although I examined the country carefully the next day I did not see either a Pumpkin Ash or *Leitneria* on its banks.

Leaving Pine Bluff, I went next to Marked Tree, Arkansas, where I fully expected to find both *Fraxinus profunda* and *Leitneria*, as this place is at the junction of the St. Francis and Little Rivers, on which further up in Missouri I had collected the two trees. I was disappointed however, in not finding either of them. Leaving Marked Tree, I went to Papaw Junction, in New Madrid County, Missouri, where I found the *Fraxinus profunda* in abundance, and where it is almost the only Ash. Here the trees were in splendid fruit. At this point the Green Ash appears to be rare, and, on account of the exceedingly dry season and the draining of the overflow of Little River by a new canal, the fruits of the Pumpkin Ash were remarkably small here, still showing, however, the characteristic form which first attracted my attention.

I saw no *Leitneria* at Papaw this year, although when I was there two seasons ago I was told that it grew in the neighboring swamp. This is probably true, as the conditions for it are exactly right. The Pumpkin Ash here is a rather medium-sized tree, growing to a height of about fifty feet, with a trunk a foot in diameter. I am of the opinion that the regions of the greatest abundance and largest development of the Ash and the *Leitneria* are somewhere in the vicinity of Big Lake, that is, in south-eastern Missouri and north-eastern Arkansas.

Courtney, Mo.

B. F. Bush.

## The Forest.

### The Shasta Fir (*Abies Shastensis*).

AMONG the conifers of the Pacific coast, two Firs, *Abies nobilis* and *Abies magnifica*, have long been a hard knot for botanists. *Abies nobilis* was described in 1833, *Abies magnifica* in 1863, and after various bibliographical vicissitudes, during which the real distinctness of the two was seriously questioned by the highest botanical authorities both in the United States and Great Britain, the essential distinctive character of the species was considered by Dr. Engelmann in 1878\* to be the exserted bracts on the cones of *A. nobilis*, a tree of the Cascade Mountains of Oregon, and the included bracts of *A. magnifica*, a tree of the Sierra Nevada of California, a position he still maintained in 1880.† Two years later, however, after a trip through Oregon and California with Professor C. S. Sargent, he expressed the opinion that the real differential mark of the two trees was the grooved leaf of *A. nobilis* and the two-keeled leaf of *A. magnifica*.‡ Now, on Mount Shasta, which is inter-

mediate in geographical position between the Cascades and the Sierra Nevada, occur large forests of a Fir with two-keeled leaves and exserted bracts. In the light of his earlier opinion Dr. Engelmann considered this tree a form of *A. nobilis*, but afterward, in the light of his later opinion, a form of *A. magnifica*.

In 1890 Mr. J. G. Lemmon took the matter up, following Dr. Engelmann's later view that the grooved leaf constituted the real character of *A. nobilis*, and ventured to describe the Mount Shasta tree as a variety, *Shastensis*, of *Abies magnifica*; and in May of the present year he published it as a distinct species, *Abies Shastensis*.

During the past summer the writer, in company with Mr. Elmer I. Applegate, of Klamath Falls, Oregon, had ample opportunity, on a journey from end to end of the Cascade Mountains of Oregon, to examine both *A. nobilis* and *A. Shastensis*. As no botanist has made this trip before, many new facts regarding the geographical distribution of plants were observed, and among other interesting things, the most of which must be deferred for later publication, the rather startling discovery was made that the bracted Fir abundant in the Crater Lake region and for nearly a hundred miles toward the north along the Cascades, is not *Abies nobilis*, as has heretofore been supposed, but is in reality *Abies Shastensis*.

We entered the Cascade Mountains from the east at a point about fifteen miles north of the Oregon-California boundary, and turning northward from Buck Lake toward Lake of the Woods, we came upon the Shasta Fir near the summit of the divide between these two lakes at an elevation of a little more than 5,000 feet. On the following day, traveling south-westward from the Lake of the Woods about two miles on the Dead Indian Road we found the tree again, on the summit of a divide of about the same altitude as the other, and probably continuous with it. These two localities, about twelve miles south-east of Mount Pitt, are situated near the point where the great Cascade Range breaks down, being separated from Mount Shasta, sixty miles to the south, by a broad gap through which the Klamath River flows oceanward from the elevated plains of the interior.

From these first localities we observed the tree northward along the Cascades at points of suitable elevation as far as the mountain immediately south of Davis Lake, one of the reservoir sources of the Deschutes River, about latitude forty-three degrees thirty-five minutes. The tree has been reported by Mr. Lemmon as occurring also westward from the Cascade-Shasta gap in various smaller ranges toward the sea, including Mount Eddy, the Trinity Mountains, Scott Mountains and the Siskiyou Mountains, all except the last lying wholly south of the Oregon-California line.

The individual localities at which we saw the tree in addition to the first two already cited, are in detail as follows: Sparingly about the base of Mount Pitt, in the vicinity of Four-mile Lake, and for three or four miles down the stream that forms its outlet; abundant along the upper part of Anna Creek Cañon to Crater Lake and down the Rogue River road on the western slope of the mountains to Whiskey

first, apparently, to bring this leaf distinction prominently before botanists, especially as a key to the difference between true *nobilis* and the Mount Shasta tree, that this leaf character had been advanced as early as 1875 (*Gardeners' Chronicle*, page 752) by Mr. Syme, the London nurseryman, as a means of distinguishing *nobilis* from *magnifica*. In the note, written by Andrew Murray, in which this character is announced there is an evident hesitation to assert its constancy. The note reads, "... There are a great many plants in this country (Great Britain) which have always been considered *Picea nobilis* (now *Abies nobilis*), which have been bought as *P. nobilis*, which have been raised from seed sent home to Great Britain as *P. nobilis* which yet have tetragonal leaves. I anticipate Mr. Syme's answer to this objection, that *P. magnifica* has been confounded with *P. nobilis* in its native country (the north-west coast of America), and that these plants with subtetragonal leaves are really *P. magnifica* raised from seed sent home as *P. nobilis* by mistake." This suggested solution of the difficulty is undoubtedly correct in the main, but the trees cultivated in Great Britain under the incorrect name *Abies nobilis*, having tetragonal or two-keeled leaves, may be not *magnifica* alone, but some of them *Shastensis*. The original importation of seeds by David Douglas in 1830, was, of course, true *nobilis*. John Jeffrey's importation, in 1851-53, was a failure, as none of his seeds grew. The seeds sent by William Murray and A. F. Beardsley a few years later reached Great Britain in good condition and were successfully grown, but none of these could have been *A. nobilis*, for that tree does not grow in the region in which they got their seeds. All the trees grown from this importation must be either *magnifica* or *Shastensis*.

\* Engelmann, *Trans. St. Louis Acad.*, iii., 602 (1878).

† Engelmann in Brewer and Watson, *Bot. Cal.*, ii., 119 (1880).

‡ Engelmann, *Bot. Gazette*, vii., 4 (1882). I find that while Dr. Engelmann was the

Creek; abundant on Huckleberry Mountain; sparingly on a mountain spur between Crater Lake and Diamond Lake; abundant on the slopes of Mount Thielson and Old Bailey; occasionally along the trail from Diamond Lake northward into the headwaters of the Umpqua; abundant on the south slope of the Calapooia Mountains near their junction with the Cascades, and sparingly on their north slope; occasionally on the lower slopes of Diamond Peak, between Summit and Crescent lakes, and on the lower divide between the latter and Odell Lake; and lastly, on the mountain east of Odell Lake and south of Davis Lake. At this point we turned eastward away from the main mountain chain, but the tree doubtless occurs at least a few miles farther north.

In the Cascade Mountains the Shasta Fir belt has an elevation of from 5,000 to 7,000 feet and the tree is usually associated with *Tsuga Pattonii*, growing chiefly in the lower part of the *Pattonii* belt, but it often also crosses the *Pinus Murrayana* belt and sometimes overlaps on its lower side the uppermost edge of the *Pinus ponderosa* belt.

In its best development, as, for example, on Huckleberry Mountain and near the summit of the Fort Klamath-Rogue River Road, it is a superb tall tree of magnificent proportions, easily the queen of the forest. Its common height is from 150 to 200 feet and its trunk diameter three or four feet. The trunks of two large, but by no means extraordinary trees near the lower camping-ground at Crater Lake measured fifteen feet seven inches and fifteen feet eight inches in circumference about four feet from the ground. The crown of a mature tree is narrowly oblong in outline, usually equaling from one-half to two-thirds the total height of the tree, supported on a straight, only slightly tapering, branchless trunk, from forty to seventy-five feet in height. The bark is of a reddish gray color on the outside, is regularly and rather deeply fissured, and within has the color of Hemlock-bark in alternating layers of dark red and reddish brown. The branchlets are extremely symmetrical in their ultimate ramifications, so that one standing beneath a tree can always distinguish it by this feature alone from *A. lasiocarpa*, *concolor*, *grandis* or *amabilis*. The large cones, described in detail below, sit erect upon the branches, and are continually suggestive of little owls.

In general appearance trees of *Abies nobilis* and *Abies Shastensis* are to me indistinguishable, though a more intimate acquaintance with them might discover some gross differences. The cones of the two trees, though very similar, can always be distinguished by one familiar with both. The cone of *A. nobilis* is the slenderer of the two, measurements of the specimens of five collectors giving an average length of 133 millimeters, and an average thickness of fifty-seven millimeters, giving a ratio of 2.33—in short, a typical, well-developed cone is noticeably more than twice as long as broad. In *A. Shastensis*, cones from six different places give an average of 131 millimeters in length by seventy millimeters in breadth, a ratio of 1.87, indicating that they are usually a little less than twice as long as broad. The cone scales of *A. Shastensis* are usually from thirty to thirty-five millimeters broad and the seeds about thirteen millimeters long, these measurements in those of *A. nobilis* being about twenty to twenty-five millimeters and ten millimeters, respectively. In external appearance the cones differ also in another way. The exposed portion of the bract is usually longer and more inclined to be obcordate in *A. nobilis*, and is abruptly reflexed and appressed to the surface of the cone, thus usually completely covering the scales. The awns of the bracts, above the marginal serrations, are commonly five to seven millimeters long. In *A. Shastensis* the awn is two to three millimeters long, and the shorter exposed part of the bract, seldom retuse at the apex, is rather loosely recurved, so that a considerable portion of the surface of the cone is commonly visible.

Probably the best diagnostic character of the tree, however, is in the leaves. Unfortunately, good series of the lower leaves of the two species are not accessible, but those of the upper branches, broken dead twigs from which can

almost always be found underneath the trees, have been examined in quantity. In both species these leaves are thick, stiff, upwardly curved, keeled on the lower surface, and often, especially on cone-bearing branches, sharp-pointed. On the upper surface of the leaves of *A. nobilis* there is, however, a sharply defined, narrow groove, while in those of *A. Shastensis* the upper surface is keeled like the lower, the cross-section therefore being rhomboidal like that of a *Picea*. The groove in the leaf of *A. nobilis* does not always reach all the way to the apex, and sometimes in the leaves situated along the middle of the upper surface of the twig, and therefore without lateral curvature, it is entirely wanting, but in the outside leaves of the twig it is invariably present.

*Abies nobilis* is primarily a tree of the Cascade Mountains, the locality best and longest known for it being Mount Hood. It has been known for several years to extend as far north along the Cascades as Mount Ranier, and now it is reported by Mr. A. J. Johnson, of Astoria, Oregon, as occurring on Mount Baker in extreme northern Washington, close to the British boundary. Southward along the Cascades in Oregon we found it as far as Browder Ridge, on the northernmost headwaters of the Mackenzie, an affluent of the Willamette. This is about fifty miles north of the northernmost point at which we found *Abies Shastensis*. Our route between these two points lay wholly on the eastern slope of the Cascades, but examination of the western slope in this region will undoubtedly show that the range of the two species approaches much more closely, if they do not, indeed, actually meet. Mr. Johnson has also reported it from the coast mountains of south-western Washington.\* The tree grows here, I am informed by Mr. B. E. Fernow, at an elevation of usually 1,500 to 3,000 feet, sometimes extending as low as 500 feet, as, for example, on the north slope of the divide between Grays River and Skamokawa River, about four miles from the sea.

By a strange misapplication of names, the history of which I do not know, the name Larch is applied by the lumbermen of Washington and Oregon to both *Abies nobilis* and *Abies Shastensis*, but I could find no evidence that the two are distinguished by them. Both are considered valuable for lumber, though from the high elevation at which they grow, and their consequent inaccessibility for the most part, neither has as yet come into the lumber market in large amount.

Though it is several years since I had the opportunity of observing *Abies magnifica* in the high Sierra Nevada of California, I recall it as a tree of the same magnificent proportions as *A. nobilis* and *A. Shastensis*, with the same deep red color of the bark within and the same geometrical regularity of the twigs. From an examination of abundant herbarium material I coincide with the view expressed by Dr. Engelmann and implied by Mr. Lemmon that it is with this tree rather than with *A. nobilis* that *A. Shastensis* is the more intimately related. Indeed, in size and relative dimensions of the cone, in the size of the scales and seeds, and in the character of the leaves the two seem to be indistinguishable, the only tangible character being the conspicuous one of protrusion or inclusion of the bracts on the cone-scales. Intergradation is not to be expected between *A. Shastensis* and *A. nobilis*, though it may hereafter be found between *A. Shastensis* and *A. magnifica*.

Department of Agriculture, Washington, D. C.

## Recent Publications.

*Insect-Life: An Introduction to Nature-Study and a Guide for Teachers, Students and Others Interested in Out-of-door Life.* By John Henry Comstock. New York: D. Appleton & Co. 1897.

In this admirable text-book the needs of the beginner in

\* *Abies nobilis* was found in August, 1896, in the valley of the Solduc River on the northern slope of the Olympic Mountains in Washington, by Professor Sargent, and was also noticed by Dr. E. Hart Merriam during the past summer in the same locality.

the study of insects have been kept constantly in mind. Although carefully adapted to the teaching of children, the book is intended for adults as well, and it would be hard to find a better introduction to entomology. The treatment of the subject results from the extensive experience of the author in teaching, and commends itself by constantly inducing personal observation, the development of this habit being one of the greatest benefits derived from such study. Part i. outlines a course of study, beginning with a series of carefully graded lessons based on material easily obtained in any part of the country, a locust being selected for the study of the parts of the body. After this knowledge has been acquired the student begins out-of-door study, and is taught about the metamorphoses of insects. The classification of insects and their near relations is then considered, and is treated in a concise and effective way; indeed, it would be hard to find a clearer exposition of the subject. A series of chapters follows on pond-life, brook-life, orchard-life, forest-life and roadside-life, in which typical insects in all the orders are taken up and treated in a simple and clear manner wholly admirable. These chapters are profusely illustrated with wood-cuts of the highest class, the figures (by Mrs. Comstock) being, in fact, one of the notable features of the work. Part ii. treats of the collection and preservation of specimens, and gives complete directions how and when to collect, how to preserve and label, and as to the different methods of breeding insects in confinement. The closing chapter is devoted to a list of some of the most useful books for beginners in entomology.

In every way the book seems to us praiseworthy and a fitting companion to the author's *Manual for the Study of Insects*.

*Bird-Life a Guide to the Study of Common Birds.* By Frank M. Chapman. New York: Appleton & Co. 1897.

The success achieved by the *Handbook of Birds of Eastern North America* leads one to expect much pleasure from the examination of another book by the same author, and this expectation is fully realized in the case of the volume before us. Beautifully printed, and illustrated by so competent an artist as Mr. E. S. Thompson, it appeals at once to the eye, and the worthiness of this appeal is confirmed by a study of the contents. The care and thought bestowed on its planning and execution have resulted in one of the best text-books ever published on that most fascinating department of Natural History—bird-life. Ornithology in this country has a record of which we may be proud indeed. Raised at once to the highest excellence by the genius of Wilson and Audubon, it has found worthy followers down to the present day, who have maintained the high standard set by them.

The steadily increasing interest in the purely popular side of the subject has been ably met by the publication of such books as the one under consideration. These books deserve the highest praise in giving to the public with absolute accuracy the results of the latest scientific knowledge. To present such knowledge in well-ordered form is a task of no little magnitude, and when, as in this instance, it is conscientiously performed, it deserves our sincere applause. The book is not addressed to professional ornithologists, but to those who desire a general knowledge of bird-life and some acquaintance with our commoner birds. The earlier chapters deal with the place of birds in Nature and their relation to man, and outline the leading facts in their life-histories. The concluding chapters describe 100 or more of the more familiar species of eastern North America and give figures of most of them, many of these ranking among the best bird portraits we have. Such figures as the downy woodpecker, phoebe, field sparrow and veery are exquisite. Throughout the volume there is everywhere evidence of care and judgment, and the reader is impressed on every page by its trustworthiness. In short, the merits of the book are of the highest order.

## Notes.

The American Forestry Association will hold a popular meeting at Tampa, Florida, in February. Dr. B. E. Fernow, Chief of the Division of Forestry, will deliver an address on National Forest Reservations and Their Management.

From the recent report of the Parks Committee of the London County Council it appears that 208 open spaces, each less than ten acres in extent, with an aggregate area of 366¼ acres, are now open in London for the enjoyment of the public.

Mr. Horatio N. Rust, of South Pasadena, California, reports an interesting case of the effects of natural root-grafting noticed by him on the Sierra Madre Mountains, where he has found that a stump of a tree of *Pseudotsuga macrocarpa* a foot in diameter, and cut down about thirty years ago, has continued to live and that a layer of wood and bark has formed over the entire top without the assistance of leaves from the stump itself.

By act of Legislature of the state of New York the College of Agriculture of Cornell University is empowered to conduct University Extension work in agriculture in this state. Scientific knowledge effecting practical agriculture is thus brought into the farmer's home in a popular and reliable form. A class which now numbers several hundreds is engaged in a course of reading in some of the fundamental principles of agriculture. Those wishing to join the class should address Professor I. P. Roberts, at Ithaca, New York. Printed matter for study is sent to applicants free of charge.

A correspondent sends us a beautiful photograph of *Rhododendron Catawbiense* at Balinie, Scotland, described as being over twenty feet in height with a spread of branches, which rest on the ground, 172 feet in circumference. This remarkable plant is about 100 years old and in still vigorous health, as is shown by the thousands of flower-clusters with which it was covered when the photograph was taken. This must be one of the oldest specimens of *Rhododendron Catawbiense* in Europe, and it is particularly interesting because it has grown to a size many times larger than this species ever attains on the mountains of Tennessee and Carolina, which are its natural home.

In the Proceedings of the California Academy of Sciences (third series, vol. i., part 2) Miss Alice Eastwood, curator of the herbarium of the Academy, distinguishes and figures under the name of *Iris Purdii* the beautiful *Iris* common in the Redwood region of Mendocino County, which has heretofore been confounded with *Iris Douglasiana*, which it resembles in its narrow red-based lanceolate spreading leaves and cream-colored flowers. From that species, however, it differs in its larger flowers, in its lighter green, less distinctly nerved, stiffer and often glaucous leaves, broader stamens and shorter, broader capsules. This *Iris*, which we believe has been successfully flowered by Max Leichtlin in his garden at Baden-Baden, is named in honor of our correspondent, Carl Purdy, of Ukiah, who first noticed and called attention to its peculiar characteristics.

With the present issue, which completes the tenth volume, the publication of GARDEN AND FOREST ends. For ten years the experiment has been tried of publishing a weekly journal devoted to horticulture and forestry, absolutely free from all trade influences, and as good as it has been possible for us to make it. This experiment, which has cost a large amount of time and money, has shown conclusively that there are not persons enough in the United States interested in the subjects which have been presented in the columns of GARDEN AND FOREST to make a journal of its class and character self-supporting. It is useless to expend more time and money on a publication which cannot be made financially successful, and must, therefore, sooner or later cease to exist.

Mr. J. H. Griffith, room 106, Tribune Building, New York, is authorized to receive money due to the Company, and to attend to any other business matters which may arise in winding up its affairs.

PRACTICAL. POPULAR. SCIENTIFICALLY EXACT.

TREATS of the science and the art of gardening, and is a trustworthy record of progress in horticulture. The weekly issues contain practical directions for cultivation under glass and out-of-doors, correspondence on seasonable topics, editorials and articles on forestry, and on legislation affecting the national forests. The contributors are botanists and specialists of the highest standing. The illustrations are original, accurate and artistic.

For the enlightened owners of gardens and woodlands this journal is invaluable.—*New York Tribune*.

Its writers are authorities in their lines and the illustrations very artistic.—*Springfield Union*.

Its character is at once dignified and pleasing, and its contents are scholarly and scientific in the exact sense.—*Chicago Evening Journal*.

Faultless in mechanical make-up, and written throughout in a polished style seldom found in the best periodical literature.—*Philadelphia Press*.

It continues on its high level—its highest level, for it has no peer. It appeals, as mere literature, to every cultivated person, and is full of information for the lover of Flowers and Trees.—*N. Y. Evening Post*.

Its arrival is the coming of a wise and intelligent and entertaining friend, who enables us to live more happily because more harmoniously with nature.—*Harper's Weekly*.

The foremost journal of its class, keeping in touch with every advance in the scientific, artistic and practical phases of horticulture and arboriculture.—*Boston Herald*.

Published weekly. \$4.00 a year.

Specimen copy free on application.

GARDEN AND FOREST PUBLISHING CO.,

Tribune Building, New York.

## Hardy Evergreens,

For Lawns, Parks and Cemeteries.

A large stock of Colorado Conifers, from six inches to ten feet high, all grown from seeds on our own grounds. Evergreen Seedlings in large quantities for Nursery and Forest planting. Shade Trees for Street and Ornamental planting. Deciduous Tree Seedlings for Forest planting.

R. DOUGLAS & SONS, Waukegan, Ill.

CAN I OBTAIN A PATENT? For a prompt answer and an honest opinion, write to MUNN & CO., who have had nearly fifty years' experience in the patent business. Communications strictly confidential. A Handbook of Information concerning Patents and how to obtain them sent free. Also a catalogue of mechanical and scientific books sent free.

Patents taken through Munn & Co. receive special notice in the *Scientific American*, and thus are brought widely before the public without cost to the inventor. This splendid paper, issued weekly, elegantly illustrated, has by far the largest circulation of any scientific work in the world. \$3 a year. Sample copies sent free.

Building Edition, monthly, \$2.50 a year. Single copies, 25 cents. Every number contains beautiful plates, in colors, and photographs of new houses, with plans, enabling builders to show the latest designs and secure contracts. Address MUNN & CO., NEW YORK, 361 BROADWAY.

## Rhododendrons and Azaleas.

IMPORTED to order from the famous English nursery of Anthony Waterer, who has supplied all the notable collections in this country, and is the largest and best grower of this class of plants in the world, and the only grower that can supply Rhododendrons grown on their own roots. I can supply fine bushy plants, well set with bloom buds, at \$8.50 per dozen; \$53.00 per 100 and upwards. (For descriptions, prices and cultural directions, see my catalogue.) Orders must be received not later than March 1st.

CHOICE NAMED LILACS ON THEIR OWN ROOTS can also be supplied by Mr. Waterer. Named Lilacs are usually budded on Privet and are practically worthless.

My *Special Import Price-list* is ready, and will be sent on request. Trees, Shrubs, Plants and Bulbs furnished from the best nurseries in America, Europe and Japan, at prices twenty-five to fifty per cent. less than those usually asked.

## APPLETON'S Popular Science Monthly.

PROSPECTUS FOR 1897.

DURING the last few years science has been unusually fruitful in important and striking discoveries. Helium and argon, the electric furnace, and the X-ray are but a few of the more startling results in the physical sciences. Similarly important if less sensational advances are being made in the fields of medicine and sanitation. Students of society and politics are coming to see the necessity for a scientific study of sociology, if we are to cope successfully with the increasing difficulties of modern civilization. We have always insisted that such a study was the only one which promised any satisfactory solution of social problems, and that many of society's worst evils were due simply to ignorance of elementary scientific principles. It is very gratifying to observe the unmistakable signs of a growing acceptance of this view that have become manifest during recent years. In our issues for 1897 we shall endeavor, as heretofore, to help on this movement by giving to the general public month by month a summary, in simple words, of what is going on in the various fields of scientific research, and of the applications of the principles thus worked out.

Among the features of special interest will be a series of papers by Professor WILLIAM Z. RIPLEY, on the Racial Geography of Europe, the subject of the last course of Lowell lectures delivered by him. The articles will be freely illustrated. DAVID A. WELLS's interesting papers on Taxation will continue, and there will be a series of carefully prepared illustrated articles on science at the universities, which is to include accounts of the leading scientific institutions and societies of the country. Education and child psychology will be given considerable space, and sanitary questions, especially in connection with household economy, will receive attention. Timely single articles may be expected from our usual contributors, among whom may be named:

Andrew D. White, David A. Wells, Appleton Morgan, James Sully, Frederick Starr, William G. Sumner, William T. Lusk, M.D., Garrett P. Serviss, David Starr Jordan, T. C. Mendenhall, Herbert Spencer, Edward S. Morse, T. Mitchell Prudden, M.D., C. Hanford Henderson, Charles Sedgwick Minot, G. T. W. Patrick, M. Allen Starr, George M. Sternberg.

Fifty Cents a number. \$5.00 per annum.

D. APPLETON & CO., Publishers,

NEW YORK.

### FERRY'S SEEDS

There has never been a time when growers should guard against failure with more care. There has never been a time when *Ferry's Seeds* were more essential. They are **always the best**. For sale by leading dealers everywhere. Insist on having them.

### FERRY'S SEED ANNUAL

is full of information for gardeners and planters. There will never be a better time than now to send for the 1897 edition. Free. D. M. Ferry & Co., Detroit, Mich.

### BUY NO INCUBATOR

and pay for it before giving it a trial.

The firm who is afraid to let you try their incubator before buying it has no faith in their machine. We will sell you ours on trial. **NOT A CENT** until

tried, and a child can run it with five minutes' attention a day. We won **FIRST PRIZE** **WORLD'S FAIR**, and will win you for a steady customer if you will only buy ours on trial. Our large catalogue will cost you five cents and give you \$100 worth of practical information on poultry and incubators and the money there is in the business. Plans for Brooders, Houses, etc., 25c. N. B.—Send us the names of three persons interested in poultry and 25 cents and we will send you "The Bicycle: Its Care and Repair," a book of 180 subjects and 80 illustrations, worth \$5 to any bicycle rider.

VON CULIN INCUBATOR CO.,  
Box 206, Delaware City, Del.

### PRIVATE GARDENERS.

We have on our register the names of reliable, experienced Gardeners. Write us at either address—**VAUGHAN'S SEED STORE**, 14 Barclay St., New York, or 84 and 86 Randolph St., Chicago. CATALOGUES FREE.

## GARDEN AND FOREST

\$4.00 a Year, in advance.

### MAILING TUBES.

The issues of *GARDEN AND FOREST* will be mailed in paste-board tubes to any subscriber, on request, for seventy-five cents in addition to the regular subscription price.

### BINDER FOR FILING.

A specially prepared binder for the convenient filing and preserving of the current issues of *GARDEN AND FOREST* will be sent, postage prepaid, to any address in the United States, on receipt of Fifty Cents. Each issue can be inserted in such a manner as to allow of the pages being opened perfectly flat, and of one or more papers being taken out and replaced at any time without disturbing the other parts.

### SPECIMEN COPIES.

The publishers will appreciate the coöperation of subscribers who will send them the addresses of persons likely to subscribe for *GARDEN AND FOREST*, and specimen copies will be sent.

### DISCONTINUANCES.

A large majority of our subscribers prefer not to have their subscriptions interrupted and their files broken, and it is, therefore, assumed, unless notification to discontinue is received, that the subscription shall continue.

## APPLETON'S Popular Science Monthly.

PROSPECTUS FOR 1897.

**D**URING the last few years science has been unusually fruitful in important and striking discoveries. Helium and argon, the electric furnace, and the X-ray are but a few of the more startling results in the physical sciences. Similarly important if less sensational advances are being made in the fields of medicine and sanitation. Students of society and politics are coming to see the necessity for a scientific study of sociology, if we are to cope successfully with the increasing difficulties of modern civilization. We have always insisted that such a study was the only one which promised any satisfactory solution of social problems, and that many of society's worst evils were due simply to ignorance of elementary scientific principles. It is very gratifying to observe the unmistakable signs of a growing acceptance of this view that have become manifest during recent years. In our issues for 1897 we shall endeavor, as heretofore, to help on this movement by giving to the general public month by month a summary, in simple words, of what is going on in the various fields of scientific research, and of the applications of the principles thus worked out.

University*, and HON. ADDISON BROWN, *President of the Torrey  
Botanical Club*.

With Four Thousand Illustrations.

In 3 volumes. Imp. 8vo.

First volume now ready, covering the subject from Ferns to Carpet  
Weed. Price, \$3.00, *special net*. Postage, 36 cts. additional.

### AN EXPERT OPINION OF THE WORK.

U. S. Department of Agriculture,  
Division of Botany, Washington, D. C.,  
September 29, 1896.

Dr. N. L. BRITTON,  
Columbia College Herbarium, New York, N. Y.

DEAR DR. BRITTON: I have examined, with the greatest pleasure, the first  
volume of your "Illustrated Flora," and I want to congratulate you on its  
success. In the line of books bearing the stamp of scientific authority, and at  
the same time adapted for popular use, this is unquestionably the best work  
ever issued on the flora of any part of the United States.

Yours very sincerely,

FREDERICK V. COVILLE.

**VON CULIN INCUBATOR CO.**,  
Box 206, Delaware City, Del.

## GARDEN AND FOREST

\$4.00 a Year, in advance.

## MAILING TUBES.

The issues of GARDEN AND FOREST will be mailed in paste-board tubes to any subscriber, on request, for seventy-five cents in addition to the regular subscription price.

## BINDER FOR FILING.

A specially prepared binder for the convenient filing and preserving of the current issues of GARDEN AND FOREST will be sent, postage prepaid, to any address in the United States, on receipt of Fifty Cents. Each issue can be inserted in such a manner as to allow of the pages being opened perfectly flat, and of one or more papers being taken out and replaced at any time without disturbing the other parts.

## SPECIMEN COPIES.

The publishers will appreciate the cooperation of subscribers who will send them the addresses of persons likely to subscribe for GARDEN AND FOREST, and specimen copies will be sent.

## DISCONTINUANCES.

A large majority of our subscribers prefer not to have their subscriptions interrupted and their files broken, and it is, therefore, assumed, unless notification to discontinue is received, that the subscription shall continue.

Advertising rates on application.

## GARDEN AND FOREST

\$4.00 a Year, in advance.

### MAILING TUBES.

The issues of GARDEN AND FOREST will be mailed in paste-board tubes to any subscriber, on request, for seventy-five cents in addition to the regular subscription price.

### BINDER FOR FILING.

A specially prepared binder for the convenient filing and preserving of the current issues of GARDEN AND FOREST will be sent, postage prepaid, to any address in the United States, on receipt of Fifty Cents. Each issue can be inserted in such a manner as to allow of the pages being opened perfectly flat, and of one or more papers being taken out and replaced at any time without disturbing the other parts.

### SPECIMEN COPIES.

The publishers will appreciate the cooperation of subscribers who will send them the addresses of persons likely to subscribe for GARDEN AND FOREST, and specimen copies will be sent.

### DISCONTINUANCES.

A large majority of our subscribers prefer not to have their subscriptions interrupted and their files broken, and it is, therefore, assumed, unless notification to discontinue is received, that the subscription shall continue.

Advertising rates on application.

### CARD No. 1.

THE undersigned beg to announce that the Stoke-Pogis Farms, Nurseries and Dairies (800 acres) are now under their joint management, Mr. Watson having charge of the business end (in conjunction with his Seed and Bulb Establishment, at Juniper and Walnut Streets, Philadelphia), and Mr. Gardner looking after the growing and propagating at Stoke-Pogis. All correspondence, inquiries for prices, etc., should be addressed to the Philadelphia office. The specialties of the Nursery Department are Hardy Ornamentals, Hedge Plants, Climbers, Fruit Trees and Bushes, Rhododendrons, Tree Pæonies, Flowering Shrubs and Herbaceous Plants. New land and good land. Everything grows thrifty and well rooted. No disease and no insects of any kind. No old rubbish. Everything new and up to date. When you need anything in their line keep these facts in mind. Have you heard of the Stoke-Pogis "Instantaneous" Hedge? Catalogue tells all about it. Free. Send for it.

G. C. WATSON,  
JOHN G. GARDNER.

### CARD No. 2.

YOU can have my list of "Bulbs for Spring Planting" for the asking; also condensed list of "Seeds for the Garden and Farm." I sell a first-class Lawn Grass at \$2.10 per bushel of 14 lbs. Is it good? Try it. Never mind what my competitors say. It has stood the test of time—the only true test. These be hard times. In the general Readjustment of Values I mean to be in the thick of the scrimmage.

G. C. WATSON, Seedsman.  
Juniper and Walnut Sts., Phila.  
March, 1897.

# Cosmopolitan Magazine

. . . . During 1897 . . . .

## An Important Series of Papers on the Conduct of Great Business Operations.

THE COSMOPOLITAN will present a valuable series of *papers on the great industries and more important operations of finance and business*. They will be from the pens of men thoroughly familiar with the subjects of which they write. No business man, however high his place in the financial world, or humble his commercial life, but will find interesting and instructive material in this series. It will constitute a very complete course of business training, and every young man just entering commercial life, and every old man, however experienced, will alike find it of value. The first of the series is in the March number, on

### "The Methods of Banking,"

by THOMAS L. JAMES, formerly Postmaster-General, many years president of the Lincoln National Bank. This paper is illustrated by portraits of twelve of the leading bankers of New York, taken for THE COSMOPOLITAN in their bank offices by flash-light.

## Julian Hawthorne Goes to India to Investigate Plague, Famine and British Rule for the Cosmopolitan.

Mr. Julian Hawthorne is on his way to India, as commissioner for THE COSMOPOLITAN, to investigate the famine and plague now desolating that land. India is the least known of the populous countries of the earth, and it is worth while sending there an American with an established reputation for fairness and sincerity, who will paint, in his own graphic style, the actual condition of affairs.

- I—The Famine in India,
- II—The Plague in India,
- III—British Rule in India,
- IV—Commerce and Finance in India,
- V—The Future of India,

will be studied for THE COSMOPOLITAN's readers by Mr.

Hawthorne. These papers will embrace one of the most important series ever presented in a magazine.

## The New Story—The War of the Worlds By Wells—to begin in April Cosmopolitan.

If Du Maurier had not chosen "The Martians" as his last title, that would have been the name of the new story of Mr. H. G. Wells, to be begun in the April COSMOPOLITAN. "The War of the Worlds" is one of the most brilliant pieces of imagination ever put in words. Swift and Poe, Jules Verne and Flammarion have all been left behind by the boldness of this new conception of Mr. Wells. Mars, growing cold through the ages, the fight for life on that planet has developed the intelligence of its people to acuteness many centuries in advance of the inhabitants of our globe. They determine to migrate and seize upon our warmer soil. England is the point at which they arrive, and the interest is intense from the first to the closing chapter.

## Does Modern College Education Educate in The Broadest and most Liberal Sense of the Term?

During 1897 THE COSMOPOLITAN will contain a series of articles bearing upon the merits and defects of the educational system of the present day—and the kind of education demanded by modern life. Some able educators have promised to contribute to the series. With a view to the broadest possible discussion, the editor of THE COSMOPOLITAN has prepared a table of subjects which seem valuable for the equipment of the young man or woman entering the world as constituted in the year of our Lord 1897. The courses of the great universities will be placed in comparison with this table, and the opinions of officers of the university sought in criticism or defense of the merits of the existing arrangement of studies. It can do no harm to have, just at the close of the nineteenth century, a general discussion of the merits of our educational methods. On the contrary, it may serve a useful purpose—and it will be interesting to know what leading educators really think of the system in vogue.

On all News Stands. Price, Ten Cents, or One Dollar a Year.

## STOKE-POGIS.

THE undersigned beg to announce that the Dept. of Farms, Nurseries and Dairies (800 acres) of Stoke-Pogis are now under their joint management, Mr. Watson having charge of the business end (in conjunction with his Seed and Bulb Establishment, at Juniper and Walnut Streets, Philadelphia), and Mr. Gardner looking after the growing and propagating at Stoke-Pogis. All correspondence, inquiries for prices, etc., should be addressed to the Philadelphia office. The specialties of the Nursery Department are Hardy Ornamentals, Hedge Plants, Climbers, Fruit Trees and Bushes, Rhododendrons, Tree Peonies, Flowering Shrubs and Herbaceous Plants. New land and good land. Everything grows thrifty and well rooted. No disease and no insects of any kind. No old rubbish. Everything new and up to date. When you need anything in their line keep these facts in mind. Have you heard of the Stoke-Pogis "Instantaneous" Hedge? Catalogue tells all about it. Free. Send for it.  
G. C. WATSON,  
JOHN G. GARDNER.

## G. C. WATSON.

YOU can have my list of "Bulbs for Spring Planting" for the asking; also condensed list of "Seeds for the Garden and Farm." I sell a first-class Lawn Grass at \$2.10 per bushel of 14 lbs. Is it good? Try it. Never mind what my competitors say. It has stood the test of time—the only true test. These be hard times. In the general Readjustment of Values I mean to be in the thick of the scrimmage.

HILL**, EVERGREEN SPECIALIST, DUNDEE, ILL.

**"MAPLE BRAND"****Canada Hard Wood Ashes.**

A CLEAN, COMPLETE MANURE

That can be applied to the lawn and garden, having all the advantages without the offence and inconvenience attending the application of stable manure. They are Nature's Complete Fertilizer. They make new soil out of worn-out lands. They produce no unhealthy or offensive odors. They are easy to handle. Liberal application of Wood Ashes to lawns and grass lands will produce that close, velvety sward so much desired, and will, at the same time, be very active in exterminating white grub and army worm. I guarantee my Ashes to be strictly pure, and to contain full amount of potash and phosphoric acid. They are nicely screened, and delivered in carload lots, in bulk, bags or barrels. Write for free pamphlet and price delivered at your station. Mention GARDEN AND FOREST.

**F. R. LALOR, Dunnville, Ontario, Canada.**

**FOR SALE.**

**CABBAGE**, Woodhaven Flat, earliest Cabbage, pkt., 10c.; oz., 40c. Cauliflower, Erfurt, pkt., 15c.; Eclipse, 25c. Celery, Golden Yellow, pkt., 10c. Lettuce, large Erfurt, pkt., 10c. Radish, Deep Scarlet Forcing and New White Tipped Forcing, oz., 10c.; lb., 60c. ASTERS, Queen of Market, the earliest and best, pkt., 10c.; oz., \$1.00. [\$4.00 A YEAR, IN ADVANCE.]

## The Mapes Manures.

*Fertilizers for Hard Times. Prices Reduced. Standard Maintained.*

BASIS of the Mapes Manures is Pure Bone, the BEST FORMS of Ammonia, Nitrogen and Potash are added and in the best proportions. They enrich the soil same as stable manure. Hundreds of farms brought up and maintained in rich condition with paying crops for some twenty years, including the past year of 1896.

### MAPES MANURES AND GRASS SOD IN FIVE YEARS' ROTATION. ALL FARM MANURE USED ON CORN.

(From *Rural New Yorker*, July 27th, 1896.)

This system has been fully explained in a pamphlet. It is enough to say here that four crops are grown—potatoes, corn, wheat and grass. The potatoes are planted after corn, with 1,500 pounds of high-grade fertilizer to the acre. After digging, the potato ground is worked over and seeded to wheat with timothy, and clover is added in the spring. After two years or more of grass, the stable manure is hauled and spread on the sod. This is all plowed under in the spring, and the ground is planted to corn—to be followed by potatoes, and so on through the rotation. The large dressing of fertilizer on the potatoes is supposed to carry through the wheat and grass. In case it is evidently needed, extra fertilizer is applied to these crops, but, generally speaking, the fertilizer used on the potatoes answers for potatoes, wheat and grass. A quantity of fertilizer is used in addition to the manure, on the corn.

### WHEAT 25 TO 30 BUSHELS PER ACRE. HAY 2½ TONS PER ACRE, WITHOUT ADDITIONAL FERTILIZER.

Mr. D. C. Lewis, Middlesex Co., N. J., in a recent interview states: "My wheat will run from 25 to 30 bushels per acre, and, even in this dry season, I have grass that will cut 2½ tons per acre. If I had dropped off on fertilizers for the past two years, my grass would have been poor stuff. At present prices for hay, an acre of grass is one of the most profitable things on the farm. You might say that we might have saved by putting less fertilizer on the potatoes, and then applying more directly to the wheat and grass. All that I can say is that our plan of crowding it upon the potato crop has always given us the best general satisfaction."

"But how did you manage to sell \$1,000 worth of potatoes last year at those awful prices?"

"I sold them as fast as they were dug, and took my chances. Prices seemed low then—30 and 40 cents per bushel—and many farmers laughed at me for selling. I knew, however, just about what potatoes cost me, and felt sure that any price above 25 cents was profit. This is a time for small profits, and I took what I could get.

In spite of the hard times and the past season of so-called disastrously low prices of farm produce there are many growers of potatoes, wheat, hay, strawberries and even apples, who have used the Mapes Manures exclusively for long periods of years who "weathered the storm" of the past depression in prices and had the same experience as related above by Mr. Lewis and Mr. Davis, and who have purchased as much of the Mapes Manures for use in 1897 as in any previous year.

Says the *American Agriculturist*, March 13, 1897, in commenting on the Mapes Manures: "It is in times like these that more than ever the BEST is the CHEAPEST."

DESCRIPTIVE PAMPHLET MAILED FREE.—This pamphlet contains full descriptions of the Mapes Manures, with full directions up to date, embracing the practical methods used by the most successful growers of potato, farm crops, in renovating grass and clover lands, and growing of truck, vegetables, tobacco and fruits, strawberries, orchards, etc.

**THE MAPES FORMULA & PERUVIAN GUANO CO.,** 143 LIBERTY STREET, NEW YORK.

Some of those who held potatoes for higher prices are holding them yet!"

"Have you not cut down your fertilizers on account of the hard times?"

"No, sir; there was no falling off in the amount of fertilizers applied in 1895. Our total outlay for fertilizers in 1895 was \$681.11, or an average of \$6.81 for each acre on the farm. You will notice that the total gross income was \$26.72 per acre."

"But have you not used a lower grade fertilizer?"

"No, I use the same brand that I always have. This is no time to cut down on quality. If the high-grade goods are cheapest in good times, they are even more desirable in hard times. My reason for keeping up to the mark with fertilizers in these hard seasons is that I cannot afford to take any chances on poor crops."

### LARGE PROFIT IN STRAWBERRIES, ETC.

Highest Quality of Fruit—Unusually Heavy Yield.

Fourteen to Fifteen Acres. Over 6,000 Quarts Strawberries (Varieties, Bubach, Warfield, Wolverton and Gandy) per Acre. Large Prices Realized. Blackberries and Raspberries.

Mr. J. A. Davis, of Greensboro, Md., reports December 9th, 1896: "The Mapes Fruit and Vine Manure has given me better satisfaction than any I have ever used. I apply 1,000 pounds per acre at the time of setting the plants. I picked not less than six thousand (6,000) quarts of strawberries to the acre. This fertilizer is equally good for blackberries and raspberries. For a general land strengthener this fertilizer surpasses any I ever used before."

Mr. L. Shanley Davis, commission merchant, 100 Barclay Street, New York, who handled 52,100 quarts of the fruit shipped to New York by J. A. Davis, Greensboro, Md., reports: "The average price received for season of 1896 for the Davis strawberries was eight and three-quarters (8¾) cents net per quart. This was two to three cents above the market price for berries during the season. The blackberries were of the Lucretia Dewberry variety. These were also very fine and sold during the season from eight (8) to twelve (12) cents per quart."

## Catalogues Received.

*These Catalogues, unless otherwise specified, will be sent free on application to the publishers of them.*

W. ATLEE BURPEE & Co., 475-477 North Fifth Street, Philadelphia, Pa.; Burpee's Manual of Thoroughbred Live Stock and Fancy Poultry.—G. CAMERER, Madison, Ind.; Vineless Sweet Potatoes.—MAX DEEGEN, Köstritz, Germany; Roses, Dahlias, Gladioli, etc.—T. J. DWYER, Cornwall, Orange County, N. Y.; Tested new varieties of Strawberries, and the best standard sorts for family use and for profitable marketing. ## STOKE-POGIS.

THE undersigned beg to announce that the Dept. of Farms, Nurseries and Dairies (800 acres) of Stoke-Pogis are now under their joint management, Mr. Watson having charge of the business end (in conjunction with his Seed and Bulb Establishment, at Juniper and Walnut Streets, Philadelphia), and Mr. Gardner looking after the growing and propagating at Stoke-Pogis. All correspondence, inquiries for prices, etc., should be addressed to the Philadelphia office. The specialties of the Nursery Department are Hardy Ornamentals, Hedge Plants, Climbers, Fruit Trees and Bushes, Rhododendrons, Tree Pæonies, Flowering Shrubs and Herbaceous Plants. New land and good land. Everything grows thrifty and well rooted. No disease and no insects of any kind. No old rubbish. Everything new and up to date. When you need anything in their line keep these facts in mind. Have you heard of the Stoke-Pogis "Instantaneous" Hedge? Catalogue tells all about it. Free. Send for it.

G. C. WATSON,  
JOHN G. GARDNER.

## G. C. WATSON.

YOU can have my list of "Bulbs for Spring Planting" for the asking; also condensed list of "Seeds for the Garden and Farm." I sell a first-class Lawn Grass at \$2.10 per bushel of 14 lbs. Is it good? Try it. Never mind what my competitors say. It has stood the test of time—the only true test. These are hard times. In the general readjustment of Values I mean to be in the thick of the scrimmage.

Prices on application. This is certainly a great opportunity to secure the finest Apples and Pears known to cultivators.

**Ellwanger & Barry,**

Mount Hope Nurseries,

Rochester, N. Y.

## Wild Ferns and Flowers

The most beautiful that grow in all countries. I grow and test them in this climate, and sell the hardiest. Hardy orchids, ferns, vines, climbers, lilies, shrubs, trees. Plants for sun and shade, for bog and rock-work, border plants, etc. Surprisingly low prices for the quality and kind of stock.

My illustrated catalogue describes about 700 kinds, tells where to plant and how to grow them. ~~My~~ 2-cent stamp.

F. H. ROSFORD, Charlotte, Vt.

## Water Hyacinths.

The most beautiful and easiest grown of aquatic plants. Beautiful rosy lilac orchid-like flowers. 10 cts. each; 3 for 25 cts.; 75 cts. per dozen, postpaid.  
O. H. STEARNS, Eustis, Florida.

## Universal Horticultural Establishment.

Headquarters for Old, New and Rare Plants.

REMEMBER the old and true saying, that "Whatsoever a Man Soweth, That Shall He Reap!" Therefore, sow only the very best Seeds if you are looking for good results.

"A Corrupt Tree Cannot Bring Forth Good Fruit," neither can poor and cheap Seeds produce satisfactory Flowers or Vegetables. I have on hand a very large stock of the choicest and best strain of both Flower and Vegetable Seeds that can possibly be obtained, including all the latest Novelties introduced this year.

I Deal in Nothing but the Best! In my general catalogue, which I will send to all intending purchasers, will be found a complete list of Vegetable and Flower Seeds, together with a list of my general stock of

Orchids, Stove and Greenhouse Plants, including Palms, Flowering and Decorative Plants, which is one of, if not the most complete collection of its kind in this country.

Trees, Shrubs and Hardy Herbaceous Plants for Spring planting are also very fine, and plants are offered at prices within the reach of every one. A most complete collection of

Bulbs for Spring and Summer Planting will also be found at my establishment, including all the latest Novelties in Tuberous-rooted Begonias, Cannas, Lilies, etc., which I import from all parts of the world, and which are the finest kinds that can be grown. I have established in connection with my business a

Landscape Department, and make a specialty of Landscape work in all its branches, and if you are contemplating the improvement of your grounds, or laying out new grounds, you cannot do better than communicate with me. I am at all times pleased to make plans, specifications or estimates for this particular line of work, which I have made a special study for many years. Write at once, with list of your needs in everything that pertains to Horticulture, to

**W. A. MANDA, Horticultural Expert, South Orange, N. J.**

**Arnold, Constable & Co.**

In the large and luxuriously equipped establishment of Arnold, Constable & Co., Broadway and Nineteenth Street, the thoughtful woman finds everything in the way of wearing apparel and all the necessities of the wardrobe to gratify every cultivated taste. The firm are past grand masters in the art of selecting the richest, most reasonable and beautiful goods the dry goods market affords, and of so placing and displaying their treasures as to please every customer within their doors.

The exhibition of model costumes is queenly in its completeness. A regal Paquin gown has a foundation skirt of shell-white satin and a second skirt of white tulle rosetted in several tiny rows. Over this is a veiling of white lace applique. The skirt is very full and round, and drapes away from the figure in lovely billows. The bodice waist of white chiffon is covered with black net spangled in steel. The cutaway pointed bolero is also richly garnished. Above the bolero are drifts of tulle, edged with cream lace and a stock of white satin. The sleeves are transparent and trimmed with chiffon and lace. The girdle is of coral ribbon.

A dainty Doucet gown suitable for almost any person is of open work etamine, in heliotrope of bar design. The bottom of the skirt is finished in tiny bands of heliotrope velvet and a pleating of corn-colored chiffon. The basque waist has a bolero of etamine trimmed with chiffon and velvet, opening over a chemisette of accordion-pleated buff chiffon. The stock is of buff chiffon and lace. The sleeves fit snugly, and are gracefully decorated in chiffon and lace. The girdle is finished with sash ends of pompadour silk. A handsome tailor-made frock is of pale gray, smooth-faced cloth, braided in a fine pattern of black and steel. The jacket opens over a violet chiffon vest and has a collar of deep pansy velvet. An exquisite white organdie has four full flounces gracefully arranged on the skirt. The yoke is square cut and finished in ruffs and the sleeves are elaborately trimmed.

The silks of Arnold, Constable & Co. are noted far and wide, and they seem more lovely than ever this season. The beauty of these materials is that they are light in weight and rich and becoming in their combinations of colors. In new shades there are to be noticed Alexandra brown, mummy brown, serpolet green, Napoleon blue, saffron, Moscow red, Sultan red and new shades in violet, mauve, ashes of roses and tan. The Roman colors in silks, surahs and taffetas will be much worn, and all sorts of patterns are exhibited in fancy foulards. But probably most favored of all are the new Louisines, which come in many patterns. They are two-toned, blocked in many colors, checked in brown, bronze and olive, magenta, buff and white and buff, black and violet and many other combinations of tints. The Persian taffetas, too, call forth much praise, as do taffeta chenilles, taffeta poplins and the clouded taffetas. In other materials are to be found the novel pauletts in lovely claret, royal purple and French gray shades, striped, blocked, checked and run through with odd threads, light gray and tan serges, chic grenadines and fancy silk and wool goods.

Any number of adjustable, swinging and dumping barrels can be used with one truck.

Rose Hill Nurseries, 407 Fifth Ave., New York.

Our 1897 Novelty Catalogue sent free on application.

## Wild Ferns and Flowers

The most beautiful that grow in all countries. I grow and test them in this climate, and sell the hardiest. Hardy orchids, ferns, vines, climbers, lilies, shrubs, trees. Plants for sun and shade, for bog and rock-work, border plants, etc. Surprisingly low prices for the quality and kind of stock.

My illustrated catalogue describes about 700 kinds, tells where to plant and how to grow them. Mailed for 2-cent stamp.

F. H. HORSFORD, Charlotte, Vt.

## Water Hyacinths.

The most beautiful and easiest grown of aquatic plants. Beautiful rosy lilac orchid-like flowers. 10 cts. each; 3 for 25 cts.; 75 cts. per dozen, postpaid.

O. H. STEARNS, Eustis, Florida.

## STOKE-POGIS.

THE undersigned beg to announce that the Dept. of Farms, Nurseries and Dairies (800 acres) of Stoke-Pogis are now under their joint management, Mr. Watson having charge of the business end (in conjunction with his Seed and Bulb Establishment, at Juniper and Walnut Streets, Philadelphia), and Mr. Gardner looking after the growing and propagating at Stoke-Pogis. All correspondence, inquiries for prices, etc., should be addressed to the Philadelphia office. The specialties of the Nursery Department are Hardy Ornamentals, Hedge Plants, Climbers, Fruit Trees and Bushes, Rhododendrons, Tree Pæonies, Flowering Shrubs and Herbaceous Plants. New land and good land. Everything grows thrifty and well rooted. No disease and no insects of any kind. No old rubbish. Everything new and up to date. When you need anything in their line keep these facts in mind. Have you heard of the Stoke-Pogis "Instantaneous" Hedge? Catalogue tells all about it. Free. Send for it.

G. C. WATSON,  
JOHN G. GARDNER.

## G. C. WATSON.

YOU can have my list of "Bulbs for Spring Planting" for the asking; also condensed list of "Seeds for the Garden and Farm." I sell a first-class Lawn Grass at \$2.10 per bushel of 14 lbs. Is it good? Try it. Never mind what my competitors say. It has stood the test of time—the only true test. These be hard times. In the general Readjustment of Values I mean to be in the thick of the scrimmage.

G. C. WATSON, Seedsman.  
Juniper and Walnut Sts., Phila.  
March, 1897.

## Readers' Wants, Situations Wanted,

## Lawns and Gardens.

How to Beautify the Home Lot, the Pleasure Ground and Garden.

By N. JÖNSSON-ROSE.

With 172 plans and illustrations by the author. Large 8vo, gilt top (in a box), \$3.50.

**Contents:** On the Study of Natural Scenery—Implements—The Plan—Grading—Drives and Walks—Grouping and Massing of Trees and Shrubs—Detached Groups and Specimen Plants—On the Proper Use of Herbaceous Plants—The Lawn—Rocks and Water—Flower Beds and Borders—Hedges—Buildings and Enclosures—On the Embellishment of the Dwelling House—The Orchard and Kitchen Garden—After-treatment—Deciduous Trees—Coniferous Trees—Flowering Trees—Ornamental Shrubs—Creepers and Vines—Herbaceous Plants—Index of Common Names—Index of Botanical Names.

Mr. Jönsson-Rose is landscape gardener in the Department of Public Parks in New York City. Under his direction Morningside Park has lately been replanted and improved, and he is now engaged in laying out Riverside Park according to plans made by himself.

This book is intended to be a help to all lovers of gardening, as applied to home surroundings; a useful aid to every owner of a country residence, to village improvement societies, landscape gardeners and young students of the art. It treats of the practical side of landscape gardening, describes the best hardy plants, and points out the proper use of each.

G. P. PUTNAM'S SONS,  
New York and London.

## Wild Ferns and Flowers

The most beautiful that grow in all countries. I grow and test them in this climate, and sell the hardiest. Hardy orchids, ferns, vines, climbers, lilies, shrubs, trees. Plants for sun and shade, for bog and rock-work, border plants, etc. Surprisingly low prices for the quality and kind of stock.

## Rhododendrons.

THE glory of every place possessing Rhododendrons is their superb bloom in the latter part of May and early June. The magnificent coloring and huge clusters of flowers in so many shades of pink, violet, rose, purple, and the delicate creamy-white, give them the first place among the evergreen shrubs, the veritable Queen of Spring. The principal feature of every fine place in England is the collection of these plants, and surely we Americans ought to appreciate and prize them even more, when our mountain ravines and brook-sides are transformed into fairy-land every summer by the bloom of our native Rhododendrons, growing and flowering in such masses as would be priceless if like effects could be produced on private grounds. Even their foliage is beautiful and most effective in the dull winter months, when their glossy green leaves add a beauty to the otherwise bare shrubbery.

The great decorative value of Rhododendrons is now fully recognized, and every year increases their popularity. This has been much hindered by the fact that so many of the most strikingly brilliant colors were not hardy in our climate, the heat and dryness of the summer and extreme cold of the winter usually proving fatal to them. But during the past five years we have expended much time and money in selecting a few varieties that will combine hardiness and the brilliancy of coloring, and the results have been so satisfactory that now we are enabled to have several exquisite colors in our collection, which a short time ago would have been impossible in this climate. We consider our plants fully acclimated now, as they have stood the severe test of four winters in our Nurseries. Of these hardy varieties the finest are the Hybrids of Catawbiense, and from these our stock is specially selected.

We take great pleasure in inviting all admirers of Rhododendrons to visit our Nurseries during the latter part of May and very early days of June, and we feel sure it will afford great pleasure to every one who sees our fine collection of over five thousand plants in the beauty of full bloom.

Single specimen plants, bushy, well furnished and well budded, at \$1.00, \$1.50, \$2.00, \$3.00, \$4.00, \$5.00, \$6.00 and \$7.50 each. First-class bushy and well-budded plants, eighteen inches to two feet, at \$12.00 to \$15.00 per dozen; \$75.00 to \$100.00 per hundred. Two to two and one-half feet, \$15.00 to \$20.00 per dozen; \$100.00 to \$125.00 per hundred. Three feet, \$20.00 to \$30.00 per dozen; \$150.00 to \$225.00 per hundred.

responding with advertisers.

## Water Hyacinths.

The most beautiful and easiest grown of aquatic  
plants. Beautiful rosy lilac orchid-like flowers. 10 cts.  
each; 3 for 25 cts.; 75 cts. per dozen, postpaid.

O. H. STEARNS, Eustis, Florida.

PRACTICAL. POPULAR. SCIENTIFICALLY EXACT.

TREATS of the science and the art of gardening, and is a trustworthy record of progress in horticulture. The weekly issues contain practical directions for cultivation under glass and out-of-doors, correspondence on seasonable topics, editorials and articles on forestry, and on legislation affecting the national forests. The contributors are botanists and specialists of the highest standing. The illustrations are original, accurate and artistic.

For the enlightened owners of gardens and woodlands this journal is invaluable.—*New York Tribune*.

Its writers are authorities in their lines and the illustrations very artistic.—*Springfield Union*.

Its character is at once dignified and pleasing, and its contents are scholarly and scientific in the exact sense.—*Chicago Evening Journal*.

Faultless in mechanical make-up, and written throughout in a polished style seldom found in the best periodical literature.—*Philadelphia Press*.

It continues on its high level—its highest level, for it has no peer. It appeals, as mere literature, to every cultivated person, and is full of information for the lover of Flowers and Trees.—*N. Y. Evening Post*.

Its arrival is the coming of a wise and intelligent and entertaining friend, who enables us to live more happily because more harmoniously with nature.—*Harper's Weekly*.

The foremost journal of its class, keeping in touch with every advance in the scientific, artistic and practical phases of horticulture and arboriculture.—*Boston Herald*.

Published weekly. \$4.00 a year.

Specimen copy free on application.

GARDEN AND FOREST PUBLISHING CO.,

Tribune Building, New York.

### THE READING NURSERY,

Special Landscape Department.  
Plans and Estimates furnished.

"The Leading New England Nursery,"  
JACOB W. MANNING, Prop.,  
READING, Mass.

FROM NOW UNTIL

## July 1st, Not Later.

There is no more useful garden material than what are known as Dutch Bulbs, Hyacinths, Tulips, Narcissi, Crocus, etc. They give for a small outlay of time and money an abundance of flowers in the house from December until April, and in the garden almost before the snow is off the ground in the spring until the middle of May. These Bulbs are grown almost exclusively in Holland, and in enormous quantities, where they are sold at very low prices. Usually they pass through the hands of two dealers, and more than double in price before reaching the retail buyer in America.

By ordering from me **NOW**, instead of waiting until fall, you save from 25 to 50 per cent. in cost, get a superior quality of bulbs not usually to be obtained at any price in this country, and have a much larger list of varieties to select from. My orders are selected and packed in Holland, and are delivered to my customers in the original packages immediately upon their arrival from Holland, perfectly fresh and in the best possible condition.

If you wish to take advantage of my very **low prices**, I must have your order **not later than July 1st**, as I import Bulbs to order only. They need not be paid for until after delivery, or taken if not of a satisfactory quality.

My price-list is now ready, and may be had for the asking:

#### A FEW OF THE PRICES.

	Per 100	Per 500
Fine Mixed Hyacinths	\$3.75	\$13.00
" " Tulips	.50	1.85
" " Crocus	.35	1.50
" Named "	.60	2.50
Narcissus Poeticus	.65	2.00
Double Daffodils	1.75	8.00

# GARDEN AND FOREST

A JOURNAL OF HORTICULTURE  
LANDSCAPE ART AND FORESTRY

JUNE · 2 · 1897

PRICE TEN CENTS.]

Copyright, 1897, by THE GARDEN AND FOREST PUBLISHING COMPANY.

[\$4.00 A YEAR, IN ADVANCE.]

## A New Trillium.

A DISTINCT form of *Trillium grandiflorum*, with flowers varying from light pink to deep rose. This new *Trillium* was discovered by us in 1894, and since then we have fully tested it to satisfy ourselves of its merit. We believe it to be a very distinct variety, and possibly a distinct species. It is a very strong grower, with bulbs twice the size of *T. grandiflorum*, and with foliage more like *T. erectum*. The flowers are very large, and vary from light pink to deep rose *when they open*, afterward turning to deeper rose. We have bloomed about 3,000 of them with *T. grandiflorum* for comparison, and find it every way a more desirable *Trillium*, growing much stronger and making more flowers to a plant, while the color is remarkably distinct.

**12 Blooming Bulbs, by mail, for \$1.00.**

We will send out these bulbs about August 1st, which is the best time to plant, and will mail to any address 12 Blooming Bulbs for \$1.00; \$6.00 per 100 by express. Special prices to the trade on application. Orders booked now.

*Those who desire can arrange with our Mr. F. L. BASSETT to advise and oversee the planting of Trilliums, Ferns, Dicentras and other native plants in a natural manner, and thus insure success.*

**WM. F. BASSETT & SON, Hammonton, N. J.**

Readers of GARDEN AND FOREST are requested to mention that paper in corresponding with advertisers.

## FLOWER POTS STANDARD.

We have the **Largest Plant in the World** for the manufacture of Flower Pots, and can supply goods in unlimited quantities and of superior quality. We also manufacture a complete assortment of Fancy Earthenware, comprising **Hanging Pots, Table Pots, Jardinieres, etc.**, to which we invite attention. Catalogues and price-list furnished on application.

**A. H. HEWS & CO., North Cambridge, Mass.**

## Colorado:

ABOUT ITS CLIMATE.

A little 16-page pamphlet which we will cheerfully mail you, free, if you drop us a note or a postal card. We are particularly anxious to put it in the hands of physicians and invalids, but others are welcome to a copy. Please address,

**B. L. WINCHELL,**  
Gen. Pass. Agt.,  
Denver, Col.

U. P., D. & G. Ry.

ORNAMENTAL

## Trees and Shrubs.

Large Stock of fine Maples, Elms, Lindens, Lilacs, Privet, Evergreens, Vines and Shrubs in great variety, which will bear examination. Catalogues on application.

**F. G. PRATT,**

Concord Nurseries, Concord, Mass.

## NUT BOOK

200 pages, illustrated, telling How to Graft, Grow, Market and Cook Them. Postpaid for \$1.00, by JOHN R. PARRY, Parry, N. J.

**FOR SALE,**

**1,500 DIFFERENT SORTS OF PLANTS,**

many of them introduced and offered only by us in the United States. Descriptive catalogue free.

**Southern California Acclimatizing Association,**  
SANTA BARBARA, CALIF.

PRACTICAL. POPULAR. SCIENTIFICALLY EXACT.

TREATS of the science and the art of gardening, and is a trustworthy record of progress in horticulture. The weekly issues contain practical directions for cultivation under glass and out-of-doors, correspondence on seasonable topics, editorials and articles on forestry, and on legislation affecting the national forests. The contributors are botanists and specialists of the highest standing. The illustrations are original, accurate and artistic.

For the enlightened owners of gardens and woodlands this journal is invaluable.—*New York Tribune*.

Its writers are authorities in their lines and the illustrations very artistic.—*Springfield Union*.

Its character is at once dignified and pleasing, and its contents are scholarly and scientific in the exact sense.—*Chicago Evening Journal*.

Faultless in mechanical make-up, and written throughout in a polished style seldom found in the best periodical literature.—*Philadelphia Press*.

It continues on its high level—its highest level, for it has no peer. It appeals, as mere literature, to every cultivated person, and is full of information for the lover of Flowers and Trees.—*N. Y. Evening Post*.

Its arrival is the coming of a wise and intelligent and entertaining friend, who enables us to live more happily because more harmoniously with nature.—*Harper's Weekly*.

The foremost journal of its class, keeping in touch with every advance in the scientific, artistic and practical phases of horticulture and arboriculture.—*Boston Herald*.

Published weekly. \$4.00 a year.

Specimen copy free on application.

GARDEN AND FOREST PUBLISHING CO.,

Tribune Building, New York.

## FOR SALE.

PANSY PLANTS, in full bloom, 5c. each; English Ivy, 4 feet high, 15c. each; Honeysuckles, ever-blooming, 3 years' old, sweet-scented, 10c. each; Carnations, rooted cuttings; Aster seeds to sell cheap.—HENRI BEAULIEU, Woodhaven, L. I., N. Y.

ROCKY MOUNTAIN Plants and Seeds, Ferns and Hardy Cacti, new and interesting sorts. Descriptive catalogue and choice sample free. A rare Cactus free, if you send addresses of five floral friends.—D. M. ANDREWS, Boulder, Colorado.

FOR SALE.—Some fine thoroughbred SCOTCH COLLIE PUPS, 3 months old. Price, \$7 for males, \$5 for females. Color, black and tan.—Address DR. MOORE, West Rupert, Vt.

FOR SALE, CHESHIRE PIGS, 4 to 6 weeks' old, \$3, with certificate of breeding, and delivered at R. R. station free of charge.—F. C. LOUCKS, Hermon, N. Y.

FLORIDA SEA SHELLS, by mail, 25 cents ½ lb., or send for \$1.00, \$3.00 or \$5.00 collection, by express. Safe delivery guaranteed. Orchids. Air Plants, that will grow very ornamental, by mail, 10 cents, 25 cents and 50 cents.—JAMES F. POWELL, Melbourne, Florida.

WANTED, Customers for 10,000 Shade Trees, 8 to 18 ft.; 10,000 Evergreens, all sizes; 3,000 Pear Trees, bearing sizes, 8 to 10 ft.; California Privet, 2 to 5 ft.; Apples, Cherries, Peaches, Quinces, Plums, Small Fruits, Asparagus and Strawberry Plants; Rhododendrons, Azaleas, Blood-leaved Maples, Golden Oaks, etc.—S. CRANE, Proprietor, Norwich Nurseries, Norwich, Ct. (Established 1870.)

## Readers' Wants, Situations Wanted.

ETC., ETC

GARDENERS.—On our register will be found the names of competent Gardeners, adapted for all positions, and we will take pleasure in sending these to any one requiring their services. Correspondence solicited.

HENRY A. DREER, Seedsman & Florist,  
14 Chestnut Street. PHILADELPHIA.

GARDENERS, FARMERS, ETC.—Employers desiring the services of reliable, first-class men to fill positions as above, or as foremen or superintendents, are invited to correspond with us. On our Register are the names of excellent men whom we have known for a long time. No fee charged to any one.—R. & J. FARQUHAR & CO., Seedsmen, 16 and 19 South Market St., Boston.

WANTED, a lady or gentleman of taste and means to establish a distinctively American style, excellently adapted to parks, gardens and grounds designed to be ornamental, commemorative and instructive. No proposal involving the subordination of designs to architects, politicians or nursery-jobbers will be entertained. Verbal conference free, but remittance, covering expenses, should be made by draft on New York or Philadelphia.—Address JAMES MACPHERSON, Landscape Gardener, Trenton, N. J.

SITUATION WANTED.—An experienced florist desires a position as foreman of an establishment where finest cut flowers are required. Persons having a position to offer where ability will be recognized are requested to correspond with NIXON H. GANO, Knightstown, Ind.

AN ENGINEER, who has had a large experience in all the details of landscape architecture, would like a position as Superintendent of a park, or with a landscape architect. Has full knowledge of topographical work, designing and construction. First-class references. Can take position at once.—Address "LANDSCAPE," care of GARDEN AND FOREST, Tribune Building, New York.

WANTED, man and wife (no children), as Working Gardener and good plain Cook. Permanent home for steady couple; Germans or Scotch preferred; must have good references. Family of four. Wages, \$40 monthly, with board and lodging.—Address E. McQUEEN GRAY, Croftonhill Ranch, Florence, New Mexico.

WANTED, at once, a private situation for my thoroughly experienced all-round Gardener. Especially good rose-grower, also good with palms, ferns, orchids, etc., and vegetables under glass; very highly recommended; temperate; moderate wages; 20 years' experience; Englishman.—Address G. H. PERKINS, East Avenue, Rochester, N. Y.

GARDENER, English, married, no family; wife dairy, poultry or board hands.—JOHN KEY-WOOD, 149 East 26th Street, New York.

[\$4.00 A YEAR, IN ADVANCE.]

## The Royal Collection of Japanese Irises.

TWO years ago, a set of Japanese Irises (*Iris Kämpferii*) were sent to me from Japan to test, which were said to be identical with the collection in the Royal Gardens. I cannot vouch for this statement, but I have never seen another collection in America or Europe that would equal it in any way. The collection contains many colors and varieties I have never seen before, and the flowers were all of remarkable size and beauty. When these Irises were in bloom they excited the greatest admiration and enthusiasm, and it was hard to convince people that these unique and exquisitely beautiful flowers were as hardy as apple trees, and as easily grown as potatoes. They will thrive in any good garden soil, but if the soil is made very rich and deep and flooded with water for a month before and during their blooming season, they will produce flowers of wonderful size, sometimes ten to twelve inches across. Planted in the Fall, they will flower the following season, but not freely, and if Fall planted, the bed containing them should have a covering of three inches of stable manure, to prevent them from being thrown out of the ground by frost. These Irises should be planted in full exposure to the sun. I am importing a considerable quantity of this superb collection from Japan, and, until the stock is exhausted, will furnish them at the low prices quoted below.

### Prices for good strong plants, delivered in November.

Set of 12 varieties, \$4.00; set of 25 varieties, \$7.50; set of 50 varieties, \$14.00; set of 100 varieties, \$25.00.

☞ For specially low prices on Japanese Pæonies, Tree and Herbaceous, Japanese Lilies, all varieties, see my import price list.

The largest and most experienced buyers throughout the country are my customers. The reason is not far to seek: I supply them with the best the world produces, and at prices twenty-five to fifty per cent. below those usually asked.

If you wish to take advantage of my very *low prices*, I must have your order **not later than July 1st**, as I import bulbs to order only. They need not be paid for until after delivery, or taken if not of a satisfactory quality. My price list is now ready, and may be had for the asking. Large buyers of Bulbs should send me their lists to be priced.

#### A FEW OF THE PRICES.

GARDENERS.—On our register will be found the names of competent Gardeners, adapted for all positions, and we will take pleasure in sending these to any one requiring their services. Correspondence solicited.

HENRY A. DREER, Seedsman & Florist, 14 Chestnut Street. PHILADELPHIA.

GARDENERS, FARMERS, ETC.—Employers desiring the services of reliable, first-class men to fill positions as above, or as foremen or superintendents, are invited to correspond with us. On our Register are the names of excellent men whom we have known for a long time. No fee charged to any one.—R. & J. FARQUHAR & CO., Seedsmen, 16 and 19 South Market St., Boston.

WANTED, a lady or gentleman of taste and means to establish a distinctively American style, excellently adapted to parks, gardens and grounds designed to be ornamental, commemorative and instructive. No proposal involving the subordination of designs to architects, politicians or nursery-jobbers will be entertained. Verbal conference free, but remittance, covering expenses, should be made by draft on New York or Philadelphia.—Address JAMES MACPHERSON, Landscape Gardener, Trenton, N. J.

SITUATION WANTED.—An experienced florist desires a position as foreman of an establishment where finest cut flowers are required. Persons having a position to offer where ability will be recognized are requested to correspond with NIXON H. GANO, Knightstown, Ind.

AN ENGINEER, who has had a large experience in all the details of landscape architecture, would like a position as Superintendent of a park, or with a landscape architect. Has full knowledge of topographical work, designing and construction. First-class references. Can take position at once.—Address "LANDSCAPE," care of GARDEN AND FOREST, Tribune Building, New York.

WANTED, man and wife (no children), as Working Gardener and good plain Cook. Permanent home for steady couple; Germans or Scotch preferred; must have good references. Family of four. Wages, \$40 monthly, with board and lodging.—Address E. McQUEEN GRAY, Croftonhill Ranch, Florence, New Mexico.

GARDENER.—Norwegian, married; thoroughly competent in greenhouses, carnation and rose-houses, grapes, vegetables, fruits and general outdoor gardening, or gentleman's place. Good references.—C. N., box 347, Hempstead, L. I.

SITUATION WANTED, in wholesale or retail cut flower or commission house, by lady who has had 10 years' practical experience in management of same. Very best of references as to character and ability.—Address Lock Box 774, Marion, Ind.

# GARDEN AND FOREST

A JOURNAL OF HORTICULTURE  
LANDSCAPE ART AND FORESTRY

JUNE 23 1897

PRICE TEN CENTS.]

Copyright, 1897, by THE GARDEN AND FOREST PUBLISHING COMPANY.

[\$4.00 A YEAR, IN ADVANCE.]

## The Royal Collection of Japanese Irises.

TWO years ago, a set of Japanese Irises (*Iris Kämpferii*) were sent to me from Japan to test, which were said to be identical with the collection in the Royal Gardens. I cannot vouch for this statement, but I have never seen another collection in America or Europe that would equal it in any way. The collection contains many colors and varieties I have never seen before, and the flowers were all of remarkable size and beauty. When these Irises were in bloom they excited the greatest admiration and enthusiasm, and it was hard to convince people that these unique and exquisitely beautiful flowers were as hardy as apple trees, and as easily grown as potatoes. They will thrive in any good garden soil, but if the soil is made very rich and deep and flooded with water for a month before and during their blooming season, they will produce flowers of wonderful size, sometimes ten to twelve inches across. Planted in the Fall, they will flower the following season, but not freely, and if Fall planted, the bed containing them should have a covering of three inches of stable manure, to prevent them from being thrown out of the ground by frost. These Irises should be planted in full exposure to the sun. I am importing a considerable quantity of this superb collection from Japan, and, until the stock is exhausted, will furnish them at the low prices quoted below.

### Prices for good strong plants, delivered in November.

Set of 12 varieties, \$4.00; set of 25 varieties, \$7.50; set of 50 varieties, \$14.00; set of 100 varieties, \$25.00.

☞ For specially low prices on Japanese Pæonies, Tree and Herbaceous, Japanese Lilies, all varieties, see my import price list.

The largest and most experienced buyers throughout the country are my customers. The reason is not far to seek: I supply them with the best the world produces, and at prices twenty-five to fifty per cent. below those usually asked.

If you wish to take advantage of my very *low prices*, I must have your order **not later than July 1st**, as I import bulbs to order only. They need not be paid for until after delivery, or taken if not of a satisfactory quality. My price list is now ready, and may be had for the asking. Large buyers of Bulbs should send me their lists to be priced.

#### A FEW OF THE PRICES.

— J. WILKINSON ELLIOTT,

Landscape Architect,  
Horticultural Buyers' Agent,

Carnegie Building, Pittsburgh, Pa.

PRACTICAL. POPULAR. SCIENTIFICALLY EXACT.

TREATS of the science and the art of gardening, and is a trustworthy record of progress in horticulture. The weekly issues contain practical directions for cultivation under glass and out-of-doors, correspondence on seasonable topics, editorials and articles on forestry, and on legislation affecting the national forests. The contributors are botanists and specialists of the highest standing. The illustrations are original, accurate and artistic.

For the enlightened owners of gardens and woodlands this journal is invaluable.—*New York Tribune*.

Its writers are authorities in their lines and the illustrations very artistic.—*Springfield Union*.

Its character is at once dignified and pleasing, and its contents are scholarly and scientific in the exact sense.—*Chicago Evening Journal*.

Faultless in mechanical make-up, and written throughout in a polished style seldom found in the best periodical literature.—*Philadelphia Press*.

It continues on its high level—its highest level, for it has no peer. It appeals, as mere literature, to every cultivated person, and is full of information for the lover of Flowers and Trees.—*N. Y. Evening Post*.

Its arrival is the coming of a wise and intelligent and entertaining friend, who enables us to live more happily because more harmoniously with nature.—*Harper's Weekly*.

The foremost journal of its class, keeping in touch with every advance in the scientific, artistic and practical phases of horticulture and arboriculture.—*Boston Herald*.

Published weekly. \$4.00 a year.

Specimen copy free on application.

GARDEN AND FOREST PUBLISHING CO.,

## The Nation

Was established in 1865 as a weekly review of literature, science, art and politics, and its editorial management has been unchanged from the first. It is conducted in a spirit of complete independence. The list of more than two hundred contributors includes most of the leading names in literature, science, art, philosophy and law in this country, and many of corresponding eminence abroad. *The Nation* presents a complete and accurate record of the world's current history, with impartial comment on questions which should occupy the attention of intelligent men. To the scholar, the student, the thinker and to all professional men it is confidently recommended as an aid to sound thinking. Its Departments are:

*The Week.* Brief comments on the most important current events, domestic and foreign.

*Editorial and Miscellaneous Articles.* Careful and moderate discussion of prominent political and social topics.

*Special Correspondence.* From all quarters of the globe, by intelligent and trustworthy observers.

*Occasional Correspondence.* Letters to the editor on every subject germane to the scope of the paper.

*Notes.* Short paragraphs, chiefly on literary, scientific, musical and dramatic topics.

*Reviews of Books.* By able writers and scholars (mainly specialists) of both hemispheres.

*Fine Arts.* Competent criticism of art exhibitions and works of art, the drama, etc.

Subscription, \$3.00 a year, post-paid. Shorter term at a proportionate rate. Address

THE NATION, 206-210 Broadway, New York.

## ANNOUNCEMENT TO FLORISTS!

We desire to announce the dissolution of the firm of SIPFLE, DOPFFEL & CO., and to introduce to the trade its successor, the SYRACUSE POTTERY CO., which will be under the management of William Dopffel and Conrad Breitschwerth. The business will be conducted as heretofore, except on a larger scale to meet the growing demand for our goods. We have accordingly enlarged our plant and capacity, and with unsurpassed facilities are now prepared to fill the largest order on short notice. Our latest improved machines are turning out the best and most serviceable flower-pots in the market, and assuring you of our intention to lead in further improvements we solicit a continuance of your patronage in the belief that we can supply just what is needed at a price and in a manner satisfactory to all. Send for price-list and samples, and we know you will give us an order. Mention GARDEN AND FOREST.

SYRACUSE POTTERY CO., Office, 403 North Salina Street, Syracuse, N. Y.

## FLOWER POTS STANDARD.

We have the Largest Plant in the World for the manufacture of Flower Pots, and can supply goods in unlimited quantities and of superior quality. We also manufacture a complete assortment of Fancy Earthenware, comprising Hanging Pots, Table Pots, Jardinieres, etc., to which we invite attention. Catalogues and price-list furnished on application.

A. H. HEWS & CO., North Cambridge, Mass.

1840. Old Colony Nurseries. 1896.

## HARDY SHRUBS, TREES, VINES

EVERGREENS AND PERENNIALS.

A large and fine stock of well-rooted plants grown in a sandy loam. Good plants, best sizes for planting, very cheap. Priced Catalogue free on application.

T. R. WATSON, Plymouth, Mass.

## Hardy Evergreens,

For Lawns, Parks and Cemeteries.

A large stock of Colorado Conifers, from six inches to ten feet high, all grown from seeds on our own grounds. Evergreen Seedlings in large quantities for Nursery and Forest planting. Shade Trees for Street and Ornamental planting. Deciduous Tree Seedlings for Forest planting.

R. DOUGLAS & SONS, Waukegan, Ill.

Prices Greatly Reduced.

## ANNOUNCEMENT TO FLORISTS!

We desire to announce the dissolution of the firm of SIFFLE, DOPFFEL & CO., and to introduce to the trade its successor, the SYRACUSE POTTERY CO., which will be under the management of William Dopffel and Conrad Breitschwerth. The business will be conducted as heretofore, except on a larger scale to meet the growing demand for our goods. We have accordingly enlarged our plant and capacity, and with unsurpassed facilities are now prepared to fill the largest order on short notice. Our latest improved machines are turning out the best and most serviceable flower-pots in the market, and assuring you of our intention to lead in further improvements we solicit a continuance of your patronage in the belief that we can supply just what is needed at a price and in a manner satisfactory to all. Send for price-list and samples, and we know you will give us an order. MENTION GARDEN AND FOREST.

SYRACUSE POTTERY CO., Office, 403 North Salina Street, Syracuse, N. Y.

## FLOWER POTS STANDARD.

We have the Largest Plant in the World for the manufacture of Flower Pots, and can supply goods in unlimited quantities and of superior quality. We also manufacture a complete assortment of Fancy Earthenware, comprising Hanging Pots, Table Pots, Jardinieres, etc., to which we invite attention. Catalogues and price-list furnished on application.

A. H. HEWS & CO., North Cambridge, Mass.

1840. Old Colony Nurseries. 1897.

## Readers' Wants, Situations Wanted, ETC., ETC.

GARDENERS.—On our register will be found the names of competent Gardeners, adapted for all positions, and we will take pleasure in sending these to any one requiring their services. Correspondence solicited.

HENRY A. DREEK, Seedsman & Florist, 14 Chestnut Street. PHILADELPHIA.

GARDENERS, FARMERS, ETC.—Employers desiring the services of reliable, first-class men to fill positions as above, or as foremen or superintendents, are invited to correspond with us. On our Register are the names of excellent men whom we have known for a long time. No fee charged to any one.—R. & J. FARQUHAR & CO., Seedsmen, 16 and 19 South Market St., Boston.

WANTED, a lady or gentleman of taste and means to establish a distinctively American style, excellently adapted to parks, gardens and grounds designed to be ornamental, commemorative and instructive. No proposal involving the subordination of designs to architects, politicians or nursery-jobbers will be entertained. Verbal conference free, but remittance, covering expenses, should be made by draft on New York or Philadelphia.—Address JAMES MACPHERSON, Landscape Gardener, Trenton, N. J.

SITUATION WANTED, as Assistant Gardener on gentleman's place, by an experienced florist and plantsman. Single, middle-aged; first-class references from employers. Willing, painstaking worker. Wishes steady situation.—A. FLORAL, West End, New Jersey.

WANTED, by a man of ten years' experience, a position as Superintendent of Cemetery, or as head-gardener on private place. The best of references furnished.—Address CHARLES A. WHITTET, Lowell, Mass.

GARDENER AND SUPERINTENDENT, married, family; 30 years' experience on large estates; up-to-date grower of high-class plants and flowers; 4 years palm specialist; medal for forcing hot-house grapes, peaches, tomatoes, cucumbers, cauliflower, lettuce, etc.; executive ability in handling men, remodeling old estates, building greenhouses, grapevines, etc., moving large trees, shrubs, etc.; 10 years' reference as to my capacity from a large estate. Late manager for the Hon. John D. Crimmins.—J. B., care of GARDEN AND FOREST, Tribune Building, New York.

SITUATION WANTED, by Gardener-Forester. Has had, in addition to garden routine, extensive experience in the culture and management of trees and shrubs, successful transplanting of large trees and laying out of grounds. Could undertake management of large estate including garden, forest and farm.—Address ARBOR, 58 E. Springfield St., Boston, Mass.

GARDENER.—Norwegian, married; thoroughly competent in greenhouses, carnation and rose-houses, grapevines, vegetables, fruits and general outdoor gardening, or gentleman's place. Good references.—C. N., box 347, Hempstead, L. I.

SITUATION WANTED, in wholesale or retail cut flower or commission house, by lady who has had 10 years' practical experience in management of same. Very best of references as to character and ability.—Address Lock Box 774, Marion, Ind.

## Books for the Summer

Familiar Features of the Roadside.

By F. SCHUYLER MATHEWS, author of "Familiar Flowers of Field and Garden," "Familiar Trees and their Leaves," etc. With 130 Illustrations by the Author. 12mo. Cloth, \$1.75.

The country roads have a life of their own of great interest if one is properly guided, and Mr. Mathews has written his book in order to set forth the life of the trees, bushes, flowers, insects, and birds which are found along the roads. He has carried out an idea which will interest those who walk, or drive, or ride a wheel in the country, and the book will be indispensable for any one who lives in or visits the country.

Familiar Trees and their Leaves.

By F. SCHUYLER MATHEWS. Illustrated with over 200 Drawings from Nature by the Author. 12mo. Cloth, \$1.75.

THIRD EDITION.

Familiar Flowers of Field and Garden.

By F. SCHUYLER MATHEWS. Illustrated with 200 Drawings by the Author, and containing an elaborate 50-page index, showing at a glance the botanical and popular names, family, color, locality, environment, and time of bloom of several hundred flowers. 12mo. Library Edition, cloth, \$1.75. Pocket Edition, flexible morocco, \$2.25.

Insect Life.

By JOHN HENRY COMSTOCK, Professor of Entomology in Cornell University. With Illustrations by ANNA BOTSFORD COMSTOCK, Member of the Society of American Wood Engravers. 12mo. Cloth, \$2.50.

Bird Life.

*A Guide to the Study of our Common Birds.*  
By FRANK M. CHAPMAN, Assistant Curator of Mammalogy and Ornithology, American Museum of Natural History. With 75 full-page Plates and numerous Text Drawings by ERNEST SETON THOMPSON. 12mo. Cloth, \$1.75.

FOURTH EDITION

Handbook of Birds of Eastern North America.

By FRANK M. CHAPMAN. With a Field Key to Our Common Land Birds, Keys to the Species, etc., and chapters on the study of Ornithology; How to Identify Birds; How to Collect and Preserve Birds, their Nests and Eggs. With nearly 200 Illustrations. 12mo. Library Edition, cloth, \$3.00; Pocket Edition, flexible morocco, \$3.50.

## Books for the Summer

### Familiar Features of the Roadside.

By F. SCHUYLER MATHEWS, author of "Familiar Flowers of Field and Garden," "Familiar Trees and their Leaves," etc. With 130 Illustrations by the Author. 12mo. Cloth, \$1.75.

The country roads have a life of their own of great interest if one is properly guided, and Mr. Mathews has written his book in order to set forth the life of the trees, bushes, flowers, insects, and birds which are found along the roads. He has carried out an idea which will interest those who walk, or drive, or ride a wheel in the country, and the book will be indispensable for any one who lives in or visits the country.

### Familiar Trees and their Leaves.

By F. SCHUYLER MATHEWS. Illustrated with over 200 Drawings from Nature by the Author. 12mo. Cloth, \$1.75.

THIRD EDITION.

### Familiar Flowers of Field and Garden.

By F. SCHUYLER MATHEWS. Illustrated with 200 Drawings by the Author, and containing an elaborate 50-page index, showing at a glance the botanical and popular names, family, color, locality, environment, and time of bloom of several hundred flowers. 12mo. Library Edition, cloth, \$1.75. Pocket Edition, flexible morocco, \$2.25.

### Insect Life.

By JOHN HENRY COMSTOCK, Professor of Entomology in Cornell University. With Illustrations by ANNA BOTSFORD COMSTOCK, Member of the Society of American Wood Engravers. 12mo. Cloth, \$2.50.

LANDSCAPE ART AND FORESTRY

AUGUST 25 1897

PRICE TEN CENTS.]

Copyright, 1897, by THE GARDEN AND FOREST PUBLISHING COMPANY.

[\$4.00 A YEAR, IN ADVANCE.]

## NOW IS THE TIME TO PLANT . . . POT-GROWN . . . Strawberries

Our collection embraces the best tested varieties, including "McKinley," introduced by us, and which has proved to be one of the most valuable here. Descriptive circular free, on request.

TO SECURE A CROP NEXT SEASON.

ELLWANGER &amp; BARRY,

MOUNT HOPE NURSERIES,

ROCHESTER, N. Y.

## Potted Strawberry Plants,

IF SET OUT IN AUGUST OR SEPTEMBER, will produce a crop of berries the next June. Our Midsummer Price-list, mailed free, describes the most reliable varieties, also offers Vegetable and Flower Seeds for Summer and Autumn sowing.

HENRY A. DREER, No. 714 Chestnut Street, Philadelphia, Pa.

## Rosa setigera,

PRAIRIE ROSE.

GARDEN AND FOREST, August 18th, 1897, page 320, says: "Rosa setigera has been described so often that it is unnecessary to do more than to refer again to its many good qualities, its hardiness and rapid growth, its freedom from the attacks of the insects which disfigure so many Roses, and the charm of its lovely pink flowers, which open about the middle of July, when the flowering time of most Roses is passed."

This uncommon plant has been propagated in our nurseries for many years. We aim to keep everything in the way of

## New & Rare Ornamental Trees, Shrubs & Vines.

New descriptive, illustrated catalogue mailed for six cents in stamps. A unique feature in our catalogue is that trees of all sizes are priced, from small seedling plants to large and well-developed ones, for immediate effect, and for single specimens or for large quantities.

## Books for the Summer

### Familiar Features of the Roadside.

By F. SCHUYLER MATHEWS, author of "Familiar Flowers of Field and Garden," "Familiar Trees and their Leaves," etc. With 130 Illustrations by the Author. 12mo. Cloth, \$1.75.

The country roads have a life of their own of great interest if one is properly guided, and Mr. Mathews has written his book in order to set forth the life of the trees, bushes, flowers, insects, and birds which are found along the roads. He has carried out an idea which will interest those who walk, or drive, or ride a wheel in the country, and the book will be indispensable for any one who lives in or visits the country.

### Familiar Trees and their Leaves.

By F. SCHUYLER MATHEWS. Illustrated with over 200 Drawings from Nature by the Author. 12mo. Cloth, \$1.75.

THIRD EDITION.

### Familiar Flowers of Field and Garden.

By F. SCHUYLER MATHEWS. Illustrated with 200 Drawings by the Author, and containing an elaborate 50-page index, showing at a glance the botanical and popular names, family, color, locality, environment, and time of bloom of several hundred flowers. 12mo. Library Edition, cloth, \$1.75. Pocket Edition, flexible morocco, \$2.25.

### Insect Life.

By JOHN HENRY COMSTOCK, Professor of Entomology in Cornell University. With Illustrations by ANNA BORSFORD COMSTOCK, Member of the Society of American Wood Engravers. 12mo. Cloth, \$2.50.

### Bird Life.

A Guide to the Study of our Common Birds.

By FRANK M. CHAPMAN, Assistant Curator of Mammalogy and Ornithology, American Museum of Natural History. With 75 full-page Plates and numerous Text Drawings by ERNEST SELON THOMPSON. 12mo. Cloth, \$1.75.

FOURTH EDITION

### Handbook of Birds of Eastern North America.

By FRANK M. CHAPMAN. With a Field Key to Our Common Land Birds, Keys to the Species, etc., and chapters on the study of Ornithology; How to Identify Birds; How to Collect and Preserve Birds, their Nests and Eggs. With nearly 200 Illustrations. 12mo. Library Edition, cloth, \$3.00; Pocket Edition, flexible morocco, \$3.50.

For sale by all booksellers; or will be sent by receipt of price to publishers.

HENRY A. DREER, No. 714 Chestnut Street, Philadelphia, Pa.

## Rosa setigera,

PRAIRIE ROSE.

GARDEN AND FOREST, August 18th, 1897, page 320, says: "Rosa setigera has been described so often that it is unnecessary to do more than to refer again to its many good qualities, its hardiness and rapid growth, its freedom from the attacks of the insects which disfigure so many Roses, and the charm of its lovely pink flowers, which open about the middle of July, when the flowering time of most Roses is passed."

This uncommon plant has been propagated in our nurseries for many years. We aim to keep everything in the way of

## New & Rare Ornamental Trees, Shrubs & Vines.

New descriptive, illustrated catalogue mailed for six cents in stamps. A unique feature in our catalogue is that trees of all sizes are priced, from small seedling plants to large and well-developed ones, for immediate effect, and for single specimens or for large quantities.

## Readers' Wants, Situations Wanted, ETC., ETC.

**GARDENERS.**—On our register will be found the names of competent Gardeners, adapted for all positions, and we will take pleasure in sending these to any one requiring their services. Correspondence solicited.

HENRY A. DREER, Seedsman & Florist,  
14 Chestnut Street. PHILADELPHIA.

**GARDENERS, FARMERS, ETC.**—Employers desiring the services of reliable, first-class men to fill positions as above, or as foremen or superintendents, are invited to correspond with us. On our Register are the names of excellent men whom we have known for a long time. No fee charged to any one.—R. & J. FARQUHAR & CO., Seedsmen, 16 and 19 South Market St., Boston.

WANTED, a lady or gentleman of taste and means to establish a distinctively American style, excellently adapted to parks, gardens and grounds designed to be ornamental, commemorative and instructive. No proposal involving the subordination of designs to architects, politicians or nursery-jobbers will be entertained. Verbal conference free, but remittance, covering expenses, should be made by draft on New York or Philadelphia.—Address JAMES MACPHERSON, Landscape Gardener, Trenton, N. J.

**POSITION WANTED,** as Gardener. Married. 25 years' experience in the culture of all kinds of greenhouse plants, fruit, vegetables, forcing grapes, mushrooms, etc., both in England and America. First-class references.—Apply GEORGE NORTON, 164 Centre Street, Bridgeport, Conn.

**SITUATION WANTED,** by a young man as Florist, private or commercial.—Address JOHN CLARK, Box 363, Portsmouth, Ohio.

**SITUATION WANTED,** in commercial or private place, by practical florist, German, age 29. Good grower of cut flowers, pot plants, palms and orchids. Good landscaper. Best American and European references.—H. RAASCH, 342 Cleveland Ave., Chicago.

**LANDSCAPE-GARDENER,** also understands the care of hot-beds, etc.; a middle-aged man; has served three years in a training school for gardeners; has the qualifications for head-gardener or foreman; wants position from 1st of December or 1st of January. First-class recommendation as to character from this country and Europe.—Address Box 145, Hillyard, Wash.

**YOUNG MAN** (22), experienced with dogs, wishes position with a kennel or on a poultry or stock farm. Good references.—FRANK W. THOMPSON, 18 Rockview Terrace, Plainfield, N. J.

**GARDENER** wishes permanent position. Life experience in greenhouses, vegetables, landscape work and the care of a private gentleman's place. Age 39; married, two children. Excellent reference.—B. A., 487 Court St., Brooklyn.

WANTED SITUATION, in a retail florist's establishment, by a young man. English, age 29, married; 18 years' experience in first-class stores. Has had a large experience in design work; quick at making up, and is well versed in both flower and plant business. Distance no object.—J. DAVIS, 513 E. Indiana Ave., Philadelphia, Pa.

**GARDENER and SUPERINTENDENT,** married, family; 30 years' experience on large estates; up-to-date grower of high-class plants and flowers; 4 years palm specialist; medal for forcing hot-house grapes, peaches, tomatoes, cucumbers, cauliflower, lettuce, etc.; executive ability in handling men, remodeling old estates, building greenhouses, graperies, etc., moving large trees, shrubs, etc.; 10 years' reference as to my capacity from a large estate. Late manager for the Hon. John D. Crimmins.—J. B., care of GARDEN AND FOREST, Tribune Building, New York.

HENRY A. DREER, No. 714 Chestnut Street, Philadelphia, Pa.

## Viburnum dentatum,

ARROW-WOOD.

GARDEN AND FOREST, in the August 25th number, illustrates this beautiful Viburnum, and says: "The Arrow-wood, Viburnum dentatum, is the most conspicuous small-flowered member of its family, for, unlike the others of this group, it is not restricted to damp ground and shaded woodland belts, but grows equally well on dry banks and open fields. The foliage is so clean and healthy-looking all summer long, with a striking red marginal coloration in autumn; the white cymes of blossoms are so showy, succeeded by almost equally showy blue berries, that one might suppose it a plant worthy of attention, but in central Pennsylvania all the specimens that have ever come under my observation have been in a wild state. Of course, this Viburnum, like our other native species, is beautiful anywhere, for, taken as a class, there are no handsomer shrubs in our forest glades. But it does seem almost unaccountable that shrubs adapted to every use and situation should have been so universally neglected by American planters."

*We have a splendid stock of this Viburnum of all sizes, as well as*

## New & Rare Ornamental Trees, Shrubs & Vines.

HENRY A. DREER, No. 714 Chestnut Street, Philadelphia, Pa.

## Rosa setigera,

PRAIRIE ROSE.

GARDEN AND FOREST, August 18th, 1897, page 320, says: "Rosa setigera has been described so often that it is unnecessary to do more than to refer again to its many good qualities, its hardiness and rapid growth, its freedom from the attacks of the insects which disfigure so many Roses, and the charm of its lovely pink flowers, which open about the middle of July, when the flowering time of most Roses is passed."

This uncommon plant has been propagated in our nurseries for many years. We aim to keep everything in the way of  
**New & Rare Ornamental Trees, Shrubs & Vines.**

New descriptive, illustrated catalogue mailed for six cents in stamps. A unique feature in our catalogue is that trees of all sizes are priced, from small seedling plants to large and well-developed ones, for immediate effect, and for single specimens or for large quantities.

THOMAS MEEHAN & SONS, Nurserymen and Landscape Engineers,  
Germantown, Phila., Pa.

## Readers' Wants, Situations Wanted, ETC., ETC.

**GARDENERS.**—On our register will be found the names of competent Gardeners, adapted for all positions, and we will take pleasure in sending these to any one requiring their services. Correspondence solicited.

**HENRY A. DREER, Seedsman & Florist,**  
14 Chestnut Street, PHILADELPHIA.

**GARDENERS, FARMERS, ETC.**—Employers desiring the services of reliable, first-class men to fill positions as above, or as foremen or superintendents, are invited to correspond with us. On our Register are the names of excellent men whom we have known for a long time. No fee charged to any one.—**R. & J. FARQUHAR & CO.,** Seedsmen, 16 and 19 South Market St., Boston.

**WANTED,** a lady or gentleman of taste and means to establish a distinctively American style, excellently adapted to parks, gardens and grounds designed to be ornamental, commemorative and instructive. No proposal involving the subordination of designs to architects, politicians or nursery-jobbers will be entertained. Verbal conference free, but remittance, covering expenses, should be made by draft on New York or Philadelphia.—Address **JAMES MACPHERSON,** Landscape Gardener, Trenton, N. J.

**POSITION WANTED,** as Gardener. Married, 25 years' experience in the culture of all kinds of greenhouse plants, fruit, vegetables, forcing graperies, mushrooms, etc., both in England and America. First-class references.—Apply **GEORGE NORTON,** 164 Centre Street, Bridgeport, Conn.

**SITUATION WANTED,** by a young man as Florist, private or commercial.—Address **JOHN CLARK,** Box 363, Portsmouth, Ohio.

**A LANDSCAPE GARDENER,** also understands the care of hot-beds, etc.; a middle-aged man; has served three years in a training school for gardeners; has the qualifications for head-gardener or foreman; wants position from 1st of December or 1st of January. First-class recommendation as to character from this country and Europe.—Address Box 145, Hillyard, Wash.

**SITUATION WANTED,** by an experienced landscape-gardener and florist, German, no children. Please address **CH. DURKOPF,** 4410 Cottage Grove Ave., Chicago, Ill.

**YOUNG MAN,** as Herdsman; eight years' practical experience in the care and feeding of stock. Understands horses, and is a good driver. Married. First-class reference.—Address **MAX BEIDEL,** Mountain Side Farm, Mahwah, Bergen Co., N. J.

**GARDENER** wishes permanent position. Life experience in greenhouses, vegetables, landscape work and the care of a private gentleman's place. Age 39; married, two children. Excellent reference.—**B. A.,** 487 Court St., Brooklyn.

**WANTED SITUATION,** in a retail florist's establishment, by a young man. English, age 29, married; 18 years' experience in first-class stores. Has had a large experience in design work; quick at making up, and is well versed in both flower and plant business. Distance no object.—**J. DAVIS,** 513 E. Indiana Ave., Philadelphia, Pa.

**GARDENER AND SUPERINTENDENT,** married, family; 30 years' experience on large estates; up-to-date grower of high-class plants and flowers; 4 years palm specialist; medal for forcing hot-house grapes, peaches, tomatoes, cucumbers, cauliflower, lettuce, etc.; executive ability in handling men, remodeling old estates, building greenhouses, graperies, etc., moving large trees, shrubs, etc.; 10 years' reference as to my capacity from a large estate. Late manager for the Hon. John D. Crimmins.—**J. B.,** care of GARDEN AND FOREST, Tribune Building, New York.

## Receiver's Sale!

THE ENTIRE STOCK OF PLANTS OF

### PITCHER & MANDA, at Short Hills, N. J.,

Will be offered for Sale, without reserve, on

### OCTOBER 4th, 5th, 6th & 7th NEXT.

The Stock consists of over **100,000 PALMS** in splendid condition, in such standard varieties as

<i>Areca Baueri</i> ,	<i>Kentia Belmoreana</i> ,	<i>Phoenix reclinata</i> ,
<i>Areca lutescens</i> ,	<i>Kentia Forsteriana</i> ,	<i>Livistona rotundifolia</i> ,
<i>Cocos Weddeliana</i> ,	<i>Latania borbonica</i> ,	Etc., etc.

Also the finest stock of **Adiantum Farleyense** ever seen in this country, and a **general assortment of other FERNS**, as well as a very fine lot of **Ornamental Foliage Plants**, containing many choice things not to be found elsewhere, together with all the **Green-houses, Packing Sheds, etc.**, and all the **Real Estate**, which will be sold in four distinct parcels, as follows:

No. 1.—Containing about 10½ acres, on which are located all the greenhouses, about 80,000 feet of glass, all in excellent condition; a good dwelling-house, containing eight rooms; stable, store rooms, packing sheds, several hundred sash and frames, etc., etc. This is a specially favorable opportunity to purchase a well-established Florist and Nursery business at a greatly reduced price, within three minutes' walk of the railroad station, and eighteen miles from New York City.

No. 2.—Contains about 3 acres, with a good dwelling-house on it, within 500 feet of the railroad station.

No. 3.—Contains about 6½ acres, now used as an Herbaceous Nursery, and is well stocked with the largest and best collection of these plants in the country. Close to railroad station.

No. 4.—Contains about 62 acres, well adapted for an excellent Nursery, Farm, or to cut up for building lots. This is situated on the main road between Short Hills and Summit, and one mile from each station.

For Catalogue, containing full particulars, write to

**JOHN N. MAY, Receiver, Short Hills, N. J.,**

OR

## MEEHANS' MONTHLY

A twenty-paged magazine of intelligent and practical horticulture, Wild Flowers and kindred subjects. Illustrated with copper and wood engravings. Each issue contains a beautiful colored plate of a Wild Flower or Fern, engraved and printed by Prang & Co. expressly for this work.

MEEHANS' MONTHLY contains practical and general information on all horticultural subjects, the care and culture of trees, shrubs, hardy plants, fruits and vegetables. The chapters on Wild Flowers and Botany are written in such a simple form that the amateur has no difficulty in gleaned information on a subject that heretofore has only been open to the student of Botany.

It is not a work catering to an idle hour and then to be thrown aside. As a volume for the library it is equal to the best works on botanical and general horticultural subjects, and, as such, it has a value far beyond the usual monthly magazines.

Subscription price, \$2 per year; \$1 for 6 months. Sample copies free.

In club with new subscription to GARDEN AND FOREST for one year for \$5.

THOMAS MEEHAN & SONS, Publishers,

Box D, GERMANTOWN, PHILADELPHIA, PA.

"The novice or amateur fond of flowers (and who is not?), knowing little or nothing of the gardener's art, finds in this periodical constant guidance and instruction conveyed in a popular form."—*Philadelphia Ledger*.

## Art Furniture and Furnishings and Interior Decorations.

"THE DECORATOR AND FURNISHER," as its title suggests, is an art journal devoted to the beautifying of the home, advocating the use of artistic furnishings, not necessarily expensive, but those which will give the greatest satisfaction to the purchaser.

It describes and illustrates modern and antique furniture and furnishings, marquetry, porcelain, carpets, carving, upholstery, etc.

This most instructive and useful magazine (now in its twenty-fifth volume) is the only one of its kind published in this country, and, in fact, there is no foreign publication like it. It gives new and original designs in furniture, the remodeling of interiors, draperies, stained glass, mosaics, etc.

Amateur House Decoration is a special feature, giving hints on every conceivable subject in relation to the adornment of the home. It describes and illustrates the art of arranging cosy corners, Moorish divans, dens, stair-landings, settees, window draperies, portières, dressing-tables, mantel-pieces, screens for dining-rooms, and for enclosing bay windows, window seats, etc., and the decoration of wall panels, dados and friezes.

Now is the Time to Subscribe. Yearly Subscription, \$4.00. Single Copies, 35 cts.

The Decorator and Furnisher, 114 Fifth Ave., New York.

Arnold  
Constable & Co.

## Underwear and Hosiery.

Women's, Men's and Children's Silk,  
Wool, Merino and Swiss Ribbed  
Underwear.

Tartan Hose & Half Hose  
in Silk, Lisle Thread and Cashmere.

Finest line of Golf Hose ever shown.

Broadway & 19th St.

NEW YORK.

## Florida's Finest Fruit.

The Pineapple is a curio. Have you ever seen it grow? Single plant 50 cents, two for 75 cents, guaranteed to fruit.

FRED C. THOMAS,

Orlando Pineries, Box 394,

Orlando, Fla.

## ANNOUNCEMENT TO FLORISTS!

We desire to announce the dissolution of the firm of SIFFLE, DOPFFEL & CO., and to introduce to the trade its successor, the SYRACUSE POTTERY CO., which will be under the management of William Dopffel and Conrad Breitschwerth. The business will be conducted as heretofore, except on a larger scale to meet the growing demand for our goods. We have accordingly enlarged our plant and capacity, and with unsurpassed facilities are now prepared to fill the largest order on short notice. Our latest improved machines are turning out the best and most serviceable flower-pots in the market, and assuring you of our intention to lead in further improvements we solicit a continuance of your patronage in the belief that we can supply just what is needed at a price and in a manner satisfactory to all. Send for price-list and samples, and we know you will give us an order. Mention GARDEN AND FOREST.

SYRACUSE POTTERY CO., Office, 403 North Salina Street, Syracuse, N. Y.

FOREIGN PERIODICAL LITERATURE

**THE LIVING AGE**

Founded by E. LITTELL in 1844.

Reproduces without abridgment the ablest articles from the Leading British periodicals in every department of Literature; also TRANSLATIONS from the French, German, Spanish, Italian and other Continental sources; also, Readings from American Magazines and from New Books.

Serial and short stories by Leading British Authors and translations from the best writers will appear during the year.

**"AN EPOCH-MAKING STORY."****"WITH ALL HER HEART." From the French of M. Rene Bazin.**

The first instalment of a COPYRIGHTED TRANSLATION of this notable story, made expressly for SERIAL PUBLICATION in THE LIVING AGE, appears in its issue of November 6th.

This novel, in its recent presentation in the Revue des Deux Mondes, aroused the greatest interest both in France and England.

Its literary and ethical qualities are so unusual that LES ANNALES LITTERAIRES ET POLITIQUES described it as "An Epoch-Making Story."

**FREE.** To all NEW SUBSCRIBERS to The Living Age for 1898, will be sent FREE the EIGHT NUMBERS of 1897 containing the first instalments of "WITH ALL HER HEART."

Published Weekly at \$6.00 a year, postpaid. Single Copies 15 cents.

**THE LIVING AGE CO., P. O. Box 5206, Boston.**

Address **MANHATTAN NURSERY CO., 47 R. Dey St., New York.**

The accompanying picture shows the NEW CYCLE REVOLVER, made by the Iver Johnson's Arms and Cycle Works of Fitchburg, Mass. Designed especially for the use of the cyclist, the revolver is meeting with much favor amongst them, as it is a good protection against vicious dogs or highwaymen. On account of its small size it can be easily carried in the pocket and, like all other "Iver Johnson" automatic revolvers, this weapon cannot be discharged except by pulling the trigger, thus making accidental discharge impossible.

## The Decorator and Furnisher

IS THE ONLY

ART JOURNAL PUBLISHED IN AMERICA

DEVOTED TO THE SUBJECT OF

## Art Furniture and Furnishings and Interior Decorations.

"THE DECORATOR AND FURNISHER," as its title suggests, is an art journal devoted to the beautifying of the home, advocating the use of artistic furnishings, not necessarily expensive, but those which will give the greatest satisfaction to the purchaser.

It describes and illustrates modern and antique furniture and furnishings, marquetry, porcelain, carpets, carving, upholstery, etc.

This most instructive and useful magazine (now in its twenty-fifth volume) is the only one of its kind published in this country, and, in fact, there is no foreign publication like it. It gives new and original designs in furniture, the remodeling of interiors, draperies, stained glass, mosaics, etc.

Amateur House Decoration is a special feature, giving hints on every conceivable subject in relation to the adornment of the home. It describes and illustrates the art of arranging cosy corners, Moorish divans, dens, stair-landings, settees, window draperies, portières, dressing-tables, mantel-pieces, screens for dining-rooms, and for enclosing bay windows, window seats, etc., and the decoration of wall panels, dados and friezes.

Now is the Time to Subscribe. Yearly Subscription, \$4.00. Single Copies, 35 cts.

The Decorator and Furnisher, 114 Fifth Ave., New York.

## Park and Cemetery.

An illustrated monthly for the advancement of Art out of doors. Practical articles of permanent value by competent authorities on subjects of special interest to Commissioners, Trustees and Superintendents of Parks and Cemeteries, and those interested in Tree Planting and Town and Village Improvements. Plans of Parks or Cemeteries, and their architectural and landscape features, illustrated every month. Subscription \$1.00 a year. R. J. HAIGHT, Publisher, 334 Dearborn Street, Chicago.

Readers of GARDEN AND FOREST are requested to mention that paper in corresponding with advertisers.

## MEEHANS' MONTHLY

"The novice or amateur fond of flowers (and who is not?), knowing little or nothing of the gardener's art, finds in this periodical constant guidance and instruction conveyed in a popular form."—Philadelphia Ledger.

"A magazine that those interested in the subject of gardening cannot well afford to be without."—Boston Herald.

A twenty-paged magazine of intelligent and practical horticulture, Wild Flowers and kindred subjects. Illustrated with copper and wood engravings. Each issue contains a beautiful colored plate of a Wild Flower or Fern, engraved and printed by Prang & Co. expressly for this work.

MEEHANS' MONTHLY contains practical and general information on all horticultural subjects, the care and culture of trees, shrubs, hardy plants, fruits and vegetables. The chapters on Wild Flowers and Botany are written in such a simple form that the amateur has no difficulty in gleaning information on a subject that heretofore has only been open to the student of Botany.

It is not a work catering to an idle hour and then to be thrown aside. As a volume for the library it is equal to the best works on botanical and general horticultural subjects, and, as such, it has a value far beyond the usual monthly magazines.

Subscription price, \$2 per year; \$1 for 6 months. Sample copies free.

In club with new subscription to GARDEN AND FOREST for one year for \$5.

## The Decorator and Furnisher

IS THE ONLY

ART JOURNAL PUBLISHED IN AMERICA

DEVOTED TO THE SUBJECT OF

### Art Furniture and Furnishings and Interior Decorations.

"THE DECORATOR AND FURNISHER," as its title suggests, is an art journal devoted to the beautifying of the home, advocating the use of artistic furnishings, not necessarily expensive, but those which will give the greatest satisfaction to the purchaser.

It describes and illustrates modern and antique furniture and furnishings, marquetry, porcelain, carpets, carving, upholstery, etc.

This most instructive and useful magazine (now in its twenty-fifth volume) is the only one of its kind published in this country, and, in fact, there is no foreign publication like it. It gives new and original designs in furniture, the remodeling of interiors, draperies, stained glass, mosaics, etc.

Amateur House Decoration is a special feature, giving hints on every conceivable subject in relation to the adornment of the home. It describes and illustrates the art of arranging cosy corners, Moorish divans, dens, stair-landings, settees, window draperies, portières, dressing-tables, mantel-pieces, screens for dining-rooms, and for enclosing bay windows, window seats, etc., and the decoration of wall panels, dados and friezes.

Now is the Time to Subscribe. Yearly Subscription, \$4.00. Single Copies, 35 cts.

The Decorator and Furnisher, 114 Fifth Ave., New York.

## Park and Cemetery.

An illustrated monthly for the advancement of Art out of doors. Practical articles of permanent value by competent authorities on subjects of special interest to Commissioners, Trustees and Superintendents of Parks and Cemeteries, and those interested in Tree Planting and Town and Village Improvements. Plans of Parks or Cemeteries, and their architectural and landscape features, illustrated every month. Subscription \$1.00 a year. R. J. HAIGHT, Publisher, 334 Dearborn Street, Chicago.

Readers of GARDEN AND FOREST are requested to mention that paper in corresponding with advertisers.

## MEEHANS' MONTHLY

"The novice or amateur fond of flowers (and who is not?), knowing little or nothing of the gardener's art, finds in this periodical constant guidance and instruction conveyed in a popular form."—Philadelphia Ledger.

"A magazine that those interested in the subject of gardening cannot well afford to be without."—Boston Herald.

A twenty-paged magazine of intelligent and practical horticulture, Wild Flowers and kindred subjects. Illustrated with copper and wood engravings. Each issue contains a beautiful colored plate of a Wild Flower or Fern, engraved and printed by Prang & Co. expressly for this work.

MEEHANS' MONTHLY contains practical and general information on all horticultural subjects, the care and culture of trees, shrubs, hardy plants, fruits and vegetables. The chapters on Wild Flowers and Botany are written in such a simple form that the amateur has no difficulty in gleaning information on a subject that heretofore has only been open to the student of Botany.

It is not a work catering to an idle hour and then to be thrown aside. As a volume for the library it is equal to the best works on botanical and general horticultural subjects, and, as such, it has a value far beyond the usual monthly magazines.

Subscription price, \$2 per year; \$1 for 6 months. Sample copies free.

In club with new subscription to GARDEN AND FOREST for one year for \$5.

THOMAS MEEHAN & SONS, Publishers,

Box D, GERMANTOWN, PHILADELPHIA, PA.

ENGRAVED PLATES FOR ALL ILLUSTRATIVE PURPOSES

320-322 Pearl Street,

NEW YORK.

The FOREST AND STREAM, now in its twenty-fifth year, deals with the purer and nobler side of outdoor sports. It is not strange that it is popular, for one characteristic of the man who casts the fly, or holds the rifle, or cuts down the twisting woodcock, or trims his sails to the wind, one trait of each of these is that he loves to read about his favorite sport.

FOREST AND STREAM treats of these sports in America, and thousands of American sportsmen write for its columns. The Western big-game hunter contributes his stories of adventures with grizzlies and mountain lion, of hunting of the deer, the elk and the mountain sheep, of shooting prairie chickens, grouse, quail and duck, of fishing, of wolf and jack rabbit coursing, and of adventures in the old days with Indians and with buffalo. So, faithful pictures are given of every phase of the Western sportsman's life; and as in the West, so in the East, the South, the North, Central

America, Mexico, Canada, everywhere.

The FOREST AND STREAM believes in the recreation to be found in the haunts of deer and grouse and trout and bass. It believes in the common sense that calls a halt in the business drive and professional grind for holiday with gun or rod or paddle—if only that afterward they may drive the faster and grind the harder. It is a journal for those who love the country and life out-of-doors. It reflects the spirit and records the experiences of the great army of outers. If

you have any sympathy with these things, you may be sure that the FOREST AND STREAM is just the paper you would like sent to your house every week.

FOREST AND STREAM is printed for grown-ups, but it is also a paper for young folks. No better reading can be given to your boy, if you want to see him grow up a manly man. Never a copy of FOREST AND STREAM leaves the press that may not with welcome—as a well-spoken guest—enter any home in the land.

Weekly, 32 pages. Terms, \$4 per year; \$2 for six months. 10 cents a copy. All newsdealers.

We are the largest American publishers of works on outdoor sports. Send for our free illustrated catalogue of books.
